The Teutonic anatomists of last century certainly deserve credit for having realised that about 85 per cent of the terms then in use were unnecessary and for having made a serious and successful attempt to get rid of them Chiefly by postal ballot they sifted out some 25,000 names, leaving as residue the B N A , which is not an international nomenclature based on scientific principles, but merely an inchoate list of 5000 Teutonic names for the various parts and structures of the human body Unfortunately the B N A has been adopted in the United States and in several of the British Dominions Even in Britain certain anatomists have recently attempted to oust the British in favour of the Teutonic nomenclature, and, although this attempt has been bitterly opposed, the student may listen to lectures in the British, dissect in the Teutonic, and converse in both with the natural result that he becomes cloudy in thought and incoherent in speech

It would be a long but by no means a difficult task to prove that the B N A is unscientific in conception, illiterate in language, and careless and inaccurate in execution It is a blunt and clumsy tool which cannot itself turn out the best class of work and which spoils those who use it for any tool capable of doing better

Destructive criticism, however, is of very limited value and a book on new lines, even if time could be found for its production would be foredoomed to failure The writer is inclined to believe that something might be accomplished by a series of short studies which might at least demonstrate what is too lightly regarded as impossible—namely, that the human body can be scientifically described in comparatively simple terms The first principle of anatomical nomenclature is that "every name shall be descriptive and as short and simple as possible" Any nomenclature which, like the Teutonic, professes that its names are "merely memory signs, and need lay no claim to description or to speculative interpretation," is already condemned out of its own mouth

The French have not adopted, and never will adopt, the B N A The time is ripe for throwing off the shackles of the inchoate nomenclature which makes anatomy so needlessly difficult and uninteresting and for producing a simple descriptive nomenclature capable of commanding the respect and winning the adhesion of all who do not confound precision with preciosity and accuracy with lumbering formality

STUDY I

The Direct Method

"Science and simplicity" should be the watchword of all scientific writing, and in accordance with this the first principle of anatomical nomenclature should be that "every name shall be descriptive and as short and simple as possible" The Austro-German nomenclature (which, because it was promulgated in 1895 at the so called International Conference of Anatomists at Basle is known as the Basle Nomina *Anatomica*, or, *for shortness*, the B N A) adopts among others the principles that "each term shall be as short and *simple as possible*" and that "the terms shall be merely *memory signs and need lay no claim to description or to* speculative interpretation" The B N A. does not state, indeed it does not apparently know, what it means by description, and it fails as a nomenclature simply because of its sublime refusal to admit that in anatomy every name should, if possible, have a meaning

What is the Direct Method?—The actual meaning of an anatomical name may in itself be of little importance, but it is only by carefully considering the meaning of each name that a satisfactory nomenclature can be evolved, since simplicity and shortness depend almost entirely upon the directness with which this meaning is expressed The incomparable value of such names as vomer, fibula, cornu, caput, and many others depends not so much upon their actual meaning as upon the directness with which that meaning is expressed How clumsy the forms os vomerinum, os fibulare, processus ceratoideus, processus capitalis or cephaloideus appear by contrast! Yet the B N A. contains many equally grotesque forms, such as os cuneiforme for cuneus os naviculare for navicula cartilago arytænoidea for arytæna, cartilago thyreoidea for thyreus, processus alaris for ala processus condyloideus for condylus The B N A. is indeed most instructive since, although many of its names are ideally descriptive, simple, and short its authors either had not the insight to discover the underlying principle or they lacked the courage or the patience to apply it They evidently realised that the ideal name for a structure or part of the body would be one which in some way related it to another structure or part, but they were puzzled by the fact that in not a few cases this was impossible They did not see that there must be an irreducible minimum of structures which while providing names for other structures, themselves require to be named on some different principle Take, for example, many of the bones Any method which should attempt to find names for the individual bones of the wrist from their relation to the other structures or parts of the body would be very cumbrous They might indeed from their position be called the os carpi proximale (or distale, as the case might be) primum, secundum, tertium, and quartum, but few would care to advocate such a terminology On the other hand, if they are to be named after their physical characters, the simplest method would be to call each bone after some object which it may be supposed in whole or in part to resemble The first bone of the wrist was originally supposed to resemble a scapha (σκαφη vessel, bowl boat), on which account it was called as in the British terminology the scaphoid or scapha like bone (σκαφο-ειδης vessel shaped) The Austro-Germans, taking scapha to mean a boat (cf skiff) latinised the name into os naviculare In either case the direct form scapha or navicula would be simpler and shorter To determine which of these two should be chosen, it should be borne in mind that scapha is the original and the shorter term, that it means a bowl rather than a boat, and that the wrist-bone under consideration, and especially the bone of the foot which bears the same name, resembles the former rather than the latter Still it must be recognised that while it is important that the bone should be called either the scapha or the navicula, it really does not seriously matter which of the two is chosen Some would cut the Gordian knot by retaining both names on the ground that they mean much the same thing and are both well known, although one is originally Greek and the other Latin This would violate one of the first principles of the B N A —namely, that "each part shall have only one name" The decision of such a question does not fall within the scope of this study, nor can any attempt be made here to deal with difficulties which may possibly arise from the use of Greek words through the medium of Latin

In many cases, then, the meaning of a name is of importance, only in so far as it ensures shortness and simplicity It is quite otherwise with names of relation, in which the meaning of the name may be instructive, e g , os frontale, os temporale os coccygis, os ischii. (It will be noticed that the B N A employs either the genitive or the adjective, but the former is certainly the more vivid, e.g , os frontis, os temporis, and it also simplifies the names of related structures)

II —*The Direct Method illustrated in the Naming of the Bones and Cartilages*

Just as the bones are the framework upon which the whole body is built up, so the names of the bones are the framework of all anatomical nomenclature Other structures and parts of the body may be named from the bones and in some cases the bones are named from the region in which they are found Often however, a bone must be named on some entirely different principle such as from its function as in the case of the atlas and axis vertebræ or from its physical resemblance to some object, such as a boat plough sieve wedge cube and so on It is natural, then in considering the principle enumerated above, to make a rapid survey of the names of the bones with which the cartilages may well be included

1 *Names of Complete Bones and Cartilages* —In naming a bone from its physical resemblance to *some object* the B N A adopts two methods

(A.) *The direct method* —In the direct method the bone is called by the actual name of the object which it is supposed to resemble, and it must, of course, be named after one object only If the resemblance is marked so much the better but at least the name is short and simple and the genitive case and adjective are easily formed, as is well seen in the following examples —

B N A	*Genitive*	*Adjective*	*Meaning*
Vomer	Vomeris.	Vomerinus	Plough
Radius	Radii	Radialis	Spoke
Fibula	Fibulæ	Fibularis	Brooch pin
Patella.	Patellæ	Patellaris	Limpet
Malleus	Mallei	Mallealis	Hammer
Incus	Incudis	Incudalis	*Anvil*
Stapes	Stapedis	Stapedius.	Stirrup

(B) *The indirect method* —In the indirect method the name is formed by combining the word os, bone, with an adjective expressing the resemblance e g —

B N A	*Meaning*
Os naviculare	Navicular or boat-shaped bone.
Os lunatum	Lunate or moon-shaped bone.
Os pisiforme.	Pisiform or pea shaped bone
Os cuboideum	Cuboid or cube-shaped bone.
Os ethmoidale	Ethmoidal or sieve-shaped bone

The indirect is the inferior method, since the name is longer, the genitive is clumsy, and the adjective is always some sort of a compromise, e g —

B N A	*Direct*	*Meaning*
1 Os naviculare Ossis navicularis Navicularis	1 Navicula. Naviculæ Navicularis	1 Boat
2. Os lunatum Ossis lunati Lunatus	2. Luna Lunæ Lunaris	2. Moon
3 Os pisiforme Ossis pisiformis Pisiformis	3 Pisum Pisi Pisalis	3 Pea
4 Os cuboideum Ossis cuboidei Cuboideus	4 Cubus Cubi Cubalis	4 Cube
5 Os ethmoidale Ossis ethmoidalis Ethmoidalis	5 Ethmus Ethmi Ethmalis	5 Sieve
6 Os cuneiforme Ossis cuneiformis Cuneiformis	6 Cuneus Cunei Cunealis	6 Wedge
7 Os sphenoidale Ossis sphenoidalis Sphenoidali	7 Sphen Sphenis Sphenalis	7 Wedge
8 Os sesamoideum Ossis sesamoidei Sesamoideus	8 Sesame Sesami Sesamalis	8 Sesame
9 Cartilago thyreoidea Cartilaginis thyreoideæ Thyreoideus	9 Thyreus Thyrei Thyrealis	9 Shield
10 Cartilago cricoidea Cartilaginis cricoideæ Cricoideus	10 Cricus Crici Cricalis	10 Signet ring
11 Cartilago arytænoidea Cartilaginis arytænoideæ Arytænoideus	11 Arytæna Arytænæ Arytænalis	11 Jug
12 Cartilago triticea Cartilaginis triticeæ Triticeus	12 Triticum Tritici Triticeus	12 Wheat grain

2 *General Terms Applied to Parts of Bones and Cartilages* —In naming parts of bones and cartilages the B N A frequently employs the direct method and with excellent result e g —

B N A	*Meaning*	*B N A*	*Meaning*
Spina.	Spine	Rostrum	Beak
Dens.	Tooth	Concha.	Shell
Cornu	Horn	Ala	Wing
Malleolus	Little hammer	Hamulus	Hooklet.
Condylus	Knuckle	Cochlea	Shell
Corona.	Crown	Jugum	Ridge
Caput	Head.	Ramus	Branch
Squama.	Scale	Collum	Neck
Sella.	Saddle	Trochlea	Pulley
Lingula.	Little tongue	Acetabulum	Cup

In the case of the second cervical vertebra the superiority of the B N A. term dens or tooth over the British odontoid process is obvious On the other hand, there are in the B N A many failures, e g —

B N A	*Direct*	*Meaning*
Processus spinosus	Spina.	Spine
Processus mammillaris	Mammilla	Nipple
Processus xiphoideus	Xiphus	Sword
Processus pterygoideus	Pteryx	Wing
Processus pyramidalis	Pyramis	Pyramid
Processus condyloideus	Condylus	Knuckle
Processus coronoideus	*Corona.*	Crown
Processus styloideus	Stylus	Style
Processus alaris	Ala	Wing
Processus coracoideus	Corax	Crow
Pars petrosa	Petra	Rock
Lamina cribrosa.	Cribrum	Sieve
Lamina papyracea	Papyrus	Papyrus
Cavitas glenoidalis	Glene	Cup

3 *Complete Names of Parts of Bones and Cartilages* —The complete name of the part of a bone or cartilage consists of a general term combined with the name of the bone or cartilage itself The B N A does this at haphazard with either the genitive or the adjective, e g —

B N A with Genitive	*B N A with adjective*
Manubrium sterni	Planum sternale
Spina ossis sphenoidalis	Lingula sphenoidalis

In all such combinations the genitive is to be preferred and direct forms should always be used In many instances the B N A is eminently satisfactory, e g —

B N A	
Spina scapulæ	Condylus tibiæ
Trochlea femoris	Ala vomeris

More often perhaps the B N A fails, e g —

B N A	*Direct*
Processus spinosus vertebræ	Spina vertebræ
Processus condyloideus mandibulæ	Condylus mandibulæ
Processus xiphoideus sterni	Xiphus sterni
Processus pterygoideus ossis sphenoidalis	Pteryx sphenis
Processus coronoideus ulnæ	Corona ulnæ
Processus styloideus radii	Stylus radii
Processus alaris ossis ethmoidalis	Ala ethmi
Lamina cribrosa ossis ethmoidalis	Cribrum ethmi
Lamina papyracea ossis ethmoidalis	Papyrus ethmi
Cavitas glenoidalis scapulæ	Glene scapulæ

The names may be even more complex, e g , (*a*) for a portion or part of a bone , (*b*) when part of a bone is in relation with some other structure, e.g —

B N A	*Direct*
(*a*) Laminæ processus pterygoidei ossis sphenoidalis	Laminæ pterygis sphenis
(*b*) Crista ethmoidalis maxillæ	Crista ethmalis maxillæ
Facies cerebralis ossis sphenoidalis	Facies cerebralis sphenis

4 *Names of Bones and Cartilages Employed in Forming Names for other Structures* —If the names of the bones were simple and short the names of many other structures could be shortened and simplified, e g —

B N A	*Direct*
Articulatio ossis pisiformis	Articulatio pisi
Articulatio calcaneocuboidea	Articulatio calcaneocubalis
Ligamentum cuboideonaviculare	Ligamentum cuboscaphale
Ligamentum navicularicuneiforme	Ligamentum scaphocuneale
Musculus thyreoarytænoideus	Musculus thyreoarytænalis
Musculus cricothyreoideus	Musculus cricothyrealis
Arteria thyreoidea	Arteria thyrealis.
Arteria ethmoidalis	Vena ethmalis
Vena chorioidea	Vena chorialis.
Emissarium condyloideum	Emissarium condylare
Nervus pterygoideus	Nervus pterygalis
Nervus ethmoidalis	Nervus ethmalis
Cisternæ subarachnoidales	Cisternæ subarachnales

III —*The Direct Method as a General Principle in Anatomical Nomenclature*

If the principle that "Every name shall be descriptive and as short and simple as possible" were adopted throughout anatomical nomenclature much "rubbish" could rapidly be removed A few examples must suffice

B N A	*Direct*
Dura mater	Dura
Arachnoidea	Arachne
Pia mater	Pia
Corpus callosum	Callosum
Corpus mammillare	Mammilla
Corpus quadrigeminum	Quadrigeminus
Corpus striatum	Striatum
Corpus restiforme	Restis
Rostrum corporis callosi	Rostrum callosi
Nuclei corporis mammillaris	Nuclei mammillæ

These names, without exception, refer to the brain and its membranes, the nomenclature and description of which afford excellent examples of "polysyllabic profundity and pompous prolixity" In a standard British work on histology are to be found in a single line the three adjectives, dural, arachnoidal, and pia matral Why not simply dural, arachnal and pial? The evil consequences of neglect of the direct method are well seen by a comparison of the principles which guided the authors of the B N A with the results attained in that nomenclature The secret of the failure of the B N A is undoubtedly its sublime refusal to admit that every name should, if possible, have a meaning No one who has not carefully studied the question can have the least idea how many terms in the B N A contradict the principles on which it is based Among such principles are the following —

(1) Each part shall have only one name

(2) Each term shall be in Latin and be philologically correct

(3) Each term shall be as short and simple as possible

(4) The terms shall be merely memory signs and need lay no claim to description or to speculative interpretation

The authors of the B N A seem to have been quite unaware how often its terms are unnecessarily and even absurdly long, how many are Greek or philologically incorrect or even actually duplicated In truth, it matters little whether anatomical terms are originally Latin or Greek and whether they are philologically correct, particularly in Britain, in these days when the average student and even teacher of medicine knows so little of either language The one thing of vital importance is that the names should be descriptive and as short and simple as possible If the official names are too often long, or complex or meaningless it is only to be expected that they will not be scrupulously employed. Everyone will find a substitute sometimes good, more often the reverse The official names must be such as no one need hesitate to use even in their official form Much of the apparent precision of the B N A is a specious preciosity indulgence in which soon destroys all sense of the value of words and the power to use them effectively Once admit that names need not mean anything and it is only too easy to speak and write in a way which is intelligible only when the meaning of the words is ignored. It is illiterate to use oid (ο-ειδης) as a simple adjectival termination—e g , taloid for talar, intercondyloid for intercondylar atloid for atlantic, and so on, and to speak of the liver as the hepatic organ is pure pomposity An eminent British surgeon writes that "The nasopharynx should be inspected by means of a post-nasal mirror or by digital exploration with the index finger" As if anyone could inspect with the finger, or could explore with the index otherwise than digitally! Again, "Brain abscesses of otitic origin occur most frequently in the temporo-sphenoidal and cerebellar lobes, more rarely in the frontal and occipital hemispheres" What are the cerebellar lobes, and where may the frontal and occipital hemispheres be found? Such disregard for precision is a poor testimonial to the real quality of science in Britain The B N A , however, is not alone responsible for these and the numerous other examples which might easily be given The British nomenclature is also to some extent guilty

IV —*The Direct Method is the Key to an International Nomenclature*

An international anatomical nomenclature is urgently needed, but conflicting national claims are difficult to reconcile Each national nomenclature, good in many ways, is in others sadly defective The only hope of reconciliation lies in a short and simple descriptive nomenclature based on principles so well defined that national partiality must give way before scientific method and practical utility

The authors of the B N A. had a magnificent opportunity but they failed because of their short-sightedness Instead of aiming at an international nomenclature, they deliberately limited themselves to forming a list of terms acceptable to German speaking anatomists, in the hope that later on they might gain the coöperation of anatomists speaking other languages Out of the 30,000 names to be found in the various standard text books of the day they succeeded in the Herculean task of clearing away about 25,000 They tried to evolve principles by the way, but these were of the most general character—e g , that "each part shall have only one name" , that "each term shall be in Latin and be philologically correct' , that "each term shall be as short and simple as possible" , that "adjectives in general shall be arranged as opposites—e g , dexter and sinister, major and minor, anterior and posterior, superficialis and profundus" Two of their principles were even contradictory—namely, that "related terms shall as far as possible be similar—e g , femur, arteria femoralis, vena femoralis nervus femoralis"—and that "the terms shall be merely memory signs and need lay no claim to description or to speculative interpretation" (or, in other words, "the terms shall be merely labels and need have no meaning")

These principles are quite in accordance with the remarkable method which they employed According to Professor Barker, "the editor took as a basis the names used in the latest large text-book of gross anatomy These terms were written down in a vertical column and the synonyms from a number of other much used text-books placed in parallel columns The lists were manifolded and a copy sent to each commissioner with the request that he mark the term of his choice, or, if he found none suitable to propose a new one for the structure concerned. Each commissioner was to return his list with comments to Professor Krause." Finally a special editing committee was appointed, consisting of Professors His, Krause, and Waldeyer, to whom was delegated "the task of giving a uniform character to the terminology as a whole" This committee must be held responsible for the failure of the B N A. Although the ore had been dug out the metal had not been extracted Each term having been balloted for independently it was now the duty of the special committee carefully to examine the list with a view to working out principles for the systematic naming of all structures belonging to each different type In naming the bones, for example, the B N A employs three methods, in naming the joints four, and so on, and these methods are employed at haphazard There is no principle to determine how many methods are necessary or which is to be chosen in any particular instance This is simply because each name is merely a "memory sign" or label quite independent of its fellows Though the structures fall into groups the members of the various groups need not be correlated in the nomenclature Each term is an isolated unit which need not even have a meaning

Such methods can never produce a scientific international nomenclature At best they may provide a list of terms for the use of anatomists of every nation in studying and teaching their science Even that is almost impossible because each term in the list has to contend against the national terms, and the B N A. has no principle which can decide in its favour Indeed, in many instances national terms are based upon principles before which the B N A. itself must bow Thus there arise from the brain and pass out of the cranium 12 nerves, of which four alone arise from the cerebrum The 12 are called in Germany the cerebral, and in Britain the cranial nerves Unless we are prepared to admit that "the terms shall be merely memory signs and need lay no claim to description or to speculative interpretation" the German term must be given up Moreover, even as a "memory sign" the accurately descriptive British term 'cranial' is preferable to the inaccurately descriptive German term "cerebral" It is throughout a war of principles, and herein lies the weakness of the B N A It has few principles and of these the one which claims that "the terms shall be merely memory signs" is of itself fatal Apart from this, however, the others are too general to decide conflicting national claims

If then the B N A is not, and never was intended to be an international nomenclature, it would be folly to allow it in Britain to oust the national nomenclature nor can we afford to leave the two to fight it out Those anatomists who have thrust the B N A into our midst may have been unwise, but those who object to it will be equally blameworthy if they merely wait and see It is their duty either to cast the B N A or the British nomenclature into an international form, or to work out a new international nomenclature from the various national terms in existence throughout the world to-day The best, probably the only, chance of success lies in remodelling the B N A according to well-defined principles, most of which can readily be evolved from the methods of the B N A itself The first principle of international nomenclature is, however, in part at least, absolutely at variance with the B N A.—' Every name must be descriptive, and as short and simple as possible ' For this the direct method is essential

REPORT OF THE LOCAL GOVERNMENT BOARD FOR 1916-17

THE forty sixth annual report of the Local Government Board has recently been issued With a view to economy it has been still further reduced in size by the exclusion of matter concerning the normal activities of the department and by the omission of statistical and other tables usually contained in these reports Part I gives interesting details of special preventive work for the relief of distress due to war for the maintenance of internment camps and for the accommodation of war refugees Part II deals with the administration of the several Working classes Acts, and of the Act of 1909 which relates to town planning Part III, with which we are more particularly concerned, relates *inter alia* to new work arising out of the war, under circumstances of special difficulty, consequent on serious depletion of the official staff

Public Health

Tuberculous disease—Under the National Insurance Act 291 residential institutions and 370 dispensaries in England and Wales have been approved by the Board, in the former of which 11,883 beds have been set apart for the treatment of tuberculosis This accommodation however, has already been proved insufficient, and proposals are under consideration for the provision of additional beds for tuberculous children In order to meet the needs of tuberculous soldiers and sailors who were about to be discharged from service on account of this infection provision has been made during the year for their treatment in residential institutions In addition to the buildings previously taken over by the military authorities for use as tuberculosis hospitals, a considerable number of beds have been devoted to that purpose in the course of 1916 Thus the adult pavilion at the Huddersfield Sanatorium has recently been completed and adapted for use as a temporary war hospital At Liverpool the Nurses' Home and the Children s Pavilion at the Fazakerley Sanatorium have been placed at the disposal of the War Office At Leeds the Killingbeck Hospital, with 60 beds, has been made available for the treatment of this disease, and additional accommodation has been provided by the town council at the Seacroft isolation hospital The Doncaster town council have lent to the military authorities their Balby Hospital for use in the treatment of tuberculosis

Venereal diseases—Substantial progress has been made in the organisation of measures for the provision of free diagnosis and treatment of venereal diseases The shortage of medical staff and of accommodation at most hospitals has presented serious obstacles Nevertheless, about 150 hospitals in this country have already expressed willingness to engage in the present campaign It is estimated that the arrangements already sanctioned will serve for a population of 18 millions out of a total of 25 millions for which accommodation has been approved The main features of the schemes for the diagnosis and treatment of venereal diseases in each county and borough will be published in a later report

Infectious diseases other than tuberculous and venereal diseases—The notification of the more important common infectious diseases is set forth in a table from which it appears that excluding measles and German measles which only became notifiable in the beginning of 1916 there has been in most cases a decrease in the numbers notified during last year as compared with 1915 This is in some degree attributable to the reduction in the civil population Especially noteworthy is the material fall in the fever attacks during 1916 Statistical details of infectious disease in England and Wales will appear in the report of the Board's medical officer to be issued as a supplement to the present report Having regard however, to war conditions the account of the work of the Board s medical inspectors acting under the medical officer's direction, will be much curtailed.

Maternity and child welfare—Government grants—Substantial progress was achieved last year in the development of schemes for safeguarding the health of expectant and nursing mothers as well as that of their offspring Provision for home visiting is known to be the most effective element in a scheme of this kind By the end of last year the councils of nearly all the large towns and a large proportion of the extra metropolitan county councils, had made some provision for home visiting The number of health visitors appointed by the local authorities which had been 600 in 1914 rose to 812 in 1915, and to 1445 by the end of February 1917 In addition health visiting has been undertaken on behalf of county councils by about 800 district nurses At the end of last year the number of salaried health visitors supported by voluntary agencies is reported to have reached 136, but a large additional number is still required in order to provide satisfactorily for the service of the whole country The maternity and child welfare centres have also increased rapidly—the number up to last Lady day having totalled 842 of which more than half were voluntary undertakings During the year 1916 the Local Government Board made grants in respect of maternity and child welfare schemes amounting to £68 000 The work however is hampered by the fact that the powers of English local authorities are more restricted than those of other parts of the United Kingdom

Medical officers on military service—Owing to the increasing demands of the war, and consequent also on the inhumanity of the enemy in sinking hospital ships, there has been a growing demand for medical men for the Army The number of medical officers released by local authorities in order to take temporary commissions with the forces now exceeds 500

URBAN VITAL STATISTICS

(Week ended Sept 1st 1917)

English and Welsh Towns—In the 96 English and Welsh towns with an aggregate civil population estimated at nearly 17 000 000 persons the annual rate of mortality was 10·6 against rates of 10 4 10 5, and 10 6 per 1000 in the three preceding weeks In London with a population exceeding 4 000 000 persons the death rate was also 10·6 or 0·1 per 1000 above that recorded in the previous week among the remaining towns the death rates ranged from 3 7 in Wallasey 4 4 in Gloucester and 4 8 in Ealing to 15 8 in Leeds 16 2 in Gateshead and 17 6 in Middlesbrough The principal epidemic diseases caused 430 deaths which corresponded to an annual rate of 1 3 per 1000 and comprised 312 from infantile diarrhœa, 41 from measles 31 from whooping-cough 27 from diphtheria, 11 from enteric fever and 8 from scarlet fever The deaths from diarrhœa, which had increased from 53 to 274 in the six preceding weeks further rose to 312, and included 95 in London 26 in Liverpool 18 in Leeds and 15 in West Ham and in Manchester The 622 cases of scarlet fever and 1022 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were respectively 8 above and 41 below the numbers remaining at the end of the previous week Of the 3455 deaths from all causes in the 96 towns 123 resulted from violence The causes of 31 deaths were uncertified of which 7 were registered in Liverpool and 5 in Gateshead but not one in London

Scotch Towns—In the 16 largest Scotch towns with an aggregate population estimated at nearly 2,500,000 persons, the annual death rate was 11·2, against 11 7 and 10·3 per 1000 in the two preceding weeks The 255 deaths in Glasgow corresponded to an annual rate of 11 8 per 1000 and included 33 from infantile diarrhœa, 4 from whooping-cough and 1 each from measles scarlet fever and diphtheria The 58 deaths in Edinburgh were equal to a rate of 9 1 per 1000 and included 1 from diphtheria.

Irish Towns—The 109 deaths in Dublin corresponded to an annual rate of 1 ·2, or 5 3 per 1000 less than that recorded in the previous week and included 26 from infantile diarrhœa and 2 from measles The 94 deaths in Belfast were equal to a rate of 12·5 per 1000, and included 5 from infantile diarrhœa, 2 from measles and one from whooping cough

THE name of Mr H Morriston Davies was inadvertently omitted from the list of the staff of University College Hospital, London given in our Students' Number (August 25th). Mr Davies recently retired from the active staff of the hospital on account of an unfortunate accident to his hand and was then appointed consulting surgeon

The War.

The Casualty List

The following names of medical officers appear among the casualties announced since our last issue —

Killed

Capt C Weller, R A M C, attached London Regiment, was a student at Guy's Hospital, London and qualified in 1910 Before joining up he was in practice at Redhill, Surrey

Drowned

Col T Daly, C M G, R A M C, qualified in Ireland in 1881, and shortly afterwards joined the Army Medical Service, being appointed surgeon-captain in August, 1885 He saw much service in India, and took part in the South African War, for which he received medals and clasps and was mentioned in despatches He joined the Expeditionary Force in France soon after the outbreak of war, and had been an Assistant Director of Medical Services since the middle of 1915 He was on his way to Egypt when he was lost in the sinking of the transport *Arcadian*

Died of Wounds

Capt J E S Wilson, M C, R A M C, attached Oxford and Bucks Light Infantry, was a student at the London Hospital and qualified in 1911 Before joining up he was in practice at Iver, Bucks, where he was medical officer to the local cottage hospital and to the Alexandra House Home for Feeble Minded Girls He died in a hospital abroad The award of the M C was recorded in The Lancet of Sept 30th, 1916, p 621

Capt J C Harris, R A M C, was a student at the Dental Hospital and at the Birmingham University, qualifying L D S R C S Eng in 1906 and M R C S, L R C P Lond in 1910 Before joining up he was in practice at Wolverhampton

Wounded

Capt E G Anderson R A M C
Capt H M Clarke, R A.M C
Capt H J De Brent R A.M C, attached Cheshire Regiment
Capt D Lees, R A M C, attached Irish Guards
Capt W H Lister, M C, R A.M C
Capt H M Anderson, R A.M C
Lieut C J E Edmonds, R A M C, attached Manchester Regiment
Capt R I Harris, M C, R A M.C
Capt G A Hodgson, R A.M C
Capt H G Janion, M C, R A M C
Capt W J Knight, M C, R A M C
Capt I Ogilvie, R A M C
Capt W Leslie, M C, R A M C
Lieut Col C H S Frankau, R A M C
Lieut R T Worthington, R A.M C
Capt E S Smalpage, Australian A.M C

Capt E D F Hayes, R A M C, attached Northampton Regiment

Casualties among the Sons of Medical Men

The following additional casualties among the sons of medical men are reported —

Second Lieut E R Osler, R F A, died of wounds, only child of Sir W Osler, Bart, Regius Professor of Medicine, Oxford University

Capt A Forbes Royal Warwickshire Regiment killed in action, elder son of the late Dr W G Forbes, of Stokesley, Yorkshire

Second Lieut E C G Hull Royal Field Artillery, killed in action elder son of Dr E G Hull of Streatham, London

Capt A V Burlton, Royal Flying Corps, killed in a flying accident at Catterick, only son of Lt Col A H. Burlton, R A.M C (retired)

[We learn that Dr L A Francis, of Uxbridge, has received unofficial information that his son, Second Lieut W F Francis, Hertfordshire Regt, is a prisoner of war at Karlsruhe, and has not been killed in action as officially reported by the War Office, and recorded in The Lancet of August 18th, p 259 *We sincerely trust that the more* recent information is correct]

OBITUARY OF THE WAR

EDWARD COPLEY WARD, M D, M S R U I,

FLEET SURGEON ROYAL NAVY

Fleet-Surgeon E C Ward, who died on August 7th at the Royal Naval Hospital, Chatham, was eldest son of the late Thomas McNamara Ward of Charleville, Co Cork. He received his medical education at the Queen's College, Cork, and Edinburgh University where he had a distinguished career, graduating at the Royal University of Ireland in 1883 A year later he joined the Royal Navy, in which he nearly completed 33 years' service

His first commission was with H M S *Northumberland* at a time when H M the King was serving as a lieutenant His sea service was considerable, and included experiences of the Cape of Good Hope, the West Coast of Africa China, Australasia, the Mediterranean Home, and Channel Fleet Stations From 1907–10 he was senior medical officer of H M Dockyard, Chatham and subsequently in the Portsmouth and Chatham Divisions of the Home Fleets At the outbreak of the war he was serving with H M S *Cornwallis*, was transferred to the *Emperor of India*, and later appointed to the R N Barracks at Chatham, where he was serving as medical transport officer up to the time of his illness He underwent a severe surgical operation from which he appeared to be recovering when uræmic symptoms set in, from which he died rather suddenly

Sir James Porter writes of Fleet-Surgeon Ward as a loyal, devoted and capable public servant "His accuracy and thoroughness were very remarkable" And a friend adds 'He was a most faithful and cheery companion, and his popularity was as universal among his shipmates as it was during his student days"

ALFRED SQUIRE TAYLOR M B EDIN ,

CAPTAIN ROYAL ARMY MEDICAL CORPS

Captain A. S Taylor, who was killed in action in Flanders on July 31st at the age of 28 years was youngest son of Rev D A. Taylor, D D Commissioner of Education in Ireland, and grandson of the late Sir David Taylor, of Belfast. He was educated at Campbell College and Edinburgh University, where he was president of the Union, and obtained his medical degrees in July, 1914 On the declaration of war he immediately volunteered for the Army serving first in France and then in Mesopotamia, whence he was invalided home On recovering his health he was sent again to the Western front attached to the Highland Light Infantry While dressing the wounds of a brother officer both he and his patient were killed instantaneously by the bursting of a shell

His chiefs write of Captain Taylor as a gallant officer and a good friend, cheery under all circumstances His keen sense of duty was seen in the quality of his work Captain Taylor was one of the most brilliant of Irish athletes, well known in the football and cricket fields In 1910 he won his Rugby cap against England and he also played for Ireland against Scotland and Wales as three-quarter

RICHARD WELLINGTON SHEGOG, M B , B CH DUB ,

CAPTAIN ROYAL ARMY MEDICAL CORPS

Captain R W Shegog who died on active service in France on August 1st was elder son of the Rev R Shegog, late rector of Skernes co Dublin He was educated at Mountjoy School and Trinity College Dublin, at both of which he took a number of exhibitions, becoming a scholar and moderator in classics at his college He was an active member of the Dublin Biological Association and was awarded a medal for research work in immunity his paper on the subject being communicated to the Association. After taking his medical degree in June 1915, he joined the Royal Army Medical Corps and had just completed two years service when his career was cut short He was wounded at a dressing station on July 31st and died from shock on the following day

Captain Shegog was recently married to Florence Margaret daughter of the late Dr W Sandham Symes, of Chesterfield and leaves a widow and infant son

EDWARD SPENCER CALTHROP M B B S LOND

SURGEON ROYAL NAVY

Surgeon E S Calthrop who died on July 30th of toxic neuritis contracted in Gallipoli was second son of the late Edward Calthrop M R C S He studied medicine at Charing Cross Hospital Medical School obtaining the diploma of the Conjoint Board in 1913 and the medical degree of London University in the following year The day before war was declared he joined the Navy, going through the whole of the Gallipoli campaign and was afterwards attached to a Naval Division in Salonika and France His chief medical officer writes of him "I believe the world generally has lost a man who would have played a good part in it There was no man who did his duty more fearlessly or conscientiously", and another of his superiors adds "His care for the wounded was marvellous, he always volunteered for any job requiring skill and pluck in carrying it out, like the brave fellow he was The greater the danger the cheerier he was '

JOHN NELIGAN, M B , B CH N U I

CAPTAIN ROYAL ARMY MEDICAL CORPS

Captain J Neligan, whose death on active service was announced in THE LANCET of June 30th, was educated at King s College, London, completing his medical studies at the National University of Ireland where he graduated in June, 1915 After holding the post of assistant medical officer to the Leavesden Asylum, Herts he obtained a commission in the Royal Army Medical Corps, and was sent to Mesopotamia with the relief force in April, 1916 He was present at the capture of Bagdad, being mentioned in Sir Stanley Maude s despatch On his way home he volunteered for a second year's service and remained at Cairo where his death occurred

SAMUEL CHARLES ELLISON, M D EDIN ,

LIEUTENANT ROYAL ARMY MEDICAL CORPS

Lieutenant S C Ellison, who died in a military hospital in Egypt on July 17th, at the age of 42, was son of the late Rev John W Ellison M A., for many years minister of the Presbyterian Church at Sunderland He took his medical studies at the University of Edinburgh and Queen's College Belfast, where he was scholar qualifying in 1902 and obtaining the M D Edin two years later After obtaining practical experience as locum - tenent for a while he settled in Small Heath, Birmingham, where he built up a large practice over a period of 12 years Shortly after the outbreak of war he intimated his readiness to join the Royal Army Medical Corps when required He was ultimately called up last May and was sent out to Egypt where he died shortly after landing At a meeting of the Small Heath Ward of the Birmingham Practitioners Union a resolution was carried conveying the sympathy of the union to Lieutenant Ellison's relatives and placing on record his colleagues high appreciation of his many good qualities especially of his unfailing good nature and the high degree of conscientiousness shown by him in all dealings with his fellow practitioners

IT was stated at the last meeting of the Bristol Board of Guardians that the cost of the new infirmary which was recently erected at Southmead, and is now used as a military hospital was £61,550

TREATMENT OF THE INVALIDED SAILOR OR SOLDIER NEW REGULATIONS OF NATIONAL HEALTH INSURANCE

Memorandum 234 I C, which has just been issued to doctors, deals with the regulations under Section 4 of the National Insurance (Part I Amendment) Act, 1917, extending medical and sanatorium benefits to all invalided *uninsured sailors and soldiers whose income from all sources does not* exceed £160 a year The Insurance Commissioners admit that the position of invalided men in general is exceptional, but not in the absence of data to prove it that an excessive burden of liability to afford treatment necessarily arises They propose therefore what they describe as an "automatic solution" of the question at issue, which is payment on an attendance basis accounts being calculated on a slight extension scale in force as regards "temporary residents" A special fund will be constituted into which 9*s* per head per annum will be paid, and this fund, if insufficient for treatment on an attendance basis, will be supplemented to the necessary extent by an Exchequer grant

The proposed scale for calculating remuneration in respect of the treatment of disabled soldiers runs as follows —

	£	*s*	*d*
(1) Visit to the patient s residence	0	2	6
(2) Attendance on the patient at the practitioner s residence, surgery or dispensary	0	2	0
(3) Special visit (i e visit paid by the patient s desire on the same day as a call received after 10 A M or on Sunday)	0	3	6
(4) Night visit (i e visit made between the hours of 8 P M and 8 A M in response to a call received between those hours)	0	5	0
(5) †Surgical operation requiring local or general anæsthetic	1	1	0
(6) Administration of general anæsthetic for the purposes of any operation included in medical benefit	1	1	0
(7) † Setting of fracture	1	1	0
(8) † Reduction of dislocation	1	1	0
(9) Mileage, per mile beyond three miles (one way only)	0	1	0
(10) Attendance on patient attending at the practitioner s residence, surgery or dispensary for the purpose only of obtaining certificate	0	1	0
(11) Special Report under Art 8 of the National Health Insurance (Medical Benefit) Regulations 1916 (No 2)	0	1	0

† Subsequent visits or attendances to count as ordinary visits or attendances

The Commissioners admit that the case of the medical profession for special consideration applies to all invalided men as a class, and all such men invalided hereafter will be treated under the new payment per attendance arrangement, each invalided man being provided on his discharge with a special form, I S 1, to complete and present to the doctor of his choice, when he receives a special (blue) medical card. "Practical difficulties of identification" prevent the arrangement being made universally retrospective, but with regard to invalided men already included in his list the doctor will be given the option of retaining him as a capitation patient or having him placed upon the new basis. If he prefers the latter a special form, I S 2, to be obtained on application to the Insurance Committee, should be filled in, or when a patient who is already receiving treatment under the ordinary arrangement discloses the fact that he has been invalided from the Forces an endorsement on p 3 of the ordinary medical card "*Invalided in (month and year)*" will insure the issue of the special (blue) medical card

Other clauses in the Memorandum deal with the reference to the Local Pensions Committees for provision of special treatment under the terms of the new Royal Warrant and the admission of practitioners not on the panel under a special agreement to the same terms and conditions of service to invalided men

TREATMENT OF DISABLED SOLDIERS IN SCOTLAND

A scheme is developing in Scotland for the succour of the soldier who finds himself on discharge still suffering from the results of service Three new hospitals in and near Edinburgh have been planned, the sites chosen, and the financial arrangements concluded Under the Pensions Ministry, which has set up district committees for the formation of hospitals, Scotland has been divided for the purpose of caring for the discharged soldier into four districts—namely, Edinburgh and South Eastern, Glasgow and South Western Dundee and Central and Aberdeen and Northern The dominating committee of all these districts is the Institution Committee for Scotland

When these committees were formed the view was taken in the Edinburgh district that five diseases demanded the provision of special hospitals—viz, neurasthenia, epilepsy, tuberculosis, advanced rheumatism, and paraplegia Arrangements have now been made to provide three institutions for the succour of three types of patient The neurasthenic hospital will be at Craig End Liberton This estate has been purchased by the city of Edinburgh corporation for £13,500 and they will lease it to the Edinburgh and South Eastern District Committee. Nearly 60 patients will be admitted there as soon as the conversion is complete. It will be the only hospital of its kind in Scotland, and it is thought that in future years the University of Edinburgh may find it a very suitable establishment for neurasthenic treatment should they follow out their idea, at present put forward, of founding a chair of neurasthenics The hospital for epileptics, the committee s second project, will be at Muriston, near Calder, 16 miles from Edinburgh This epileptic colony may also be retained as a permanent institution For orthopædic cases the Edinburgh Committee has secured a building in Edinburgh which, with comparatively small cost can be transformed into a temporary hospital The aim was to place the new hospital near a centre where discharged disabled soldiers are trained for civilian employment, and it has been located accordingly in the neighbourhood of an institution now controlled by the educational authorities of the city for the purposes of technical instruction Arrangements have been made for the treatment of *discharged men suffering from excessive* rheumatism at Red Cross auxiliary hospitals at Moffat and Strathpeffer, while consumptive and paraplegic patients will come under the special care of existing Edinburgh institutions The financial burden of these enterprises is being borne partly by the Treasury but in greater measure by the Red Cross Society

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

To be temporary Surgeons: C J A. McKillop and A. Selby Green

The following appointments have been notified:—Fleet Surgeons W G Westcott to *Edgar* and T H Vickers to *Hecla* Staff-Surgeons P L. Crosbie to *Apollo* Surgeons W C Carson to *Victory* and J L. THE LUMLEIAN LECTURES AND MEDICAL RESEARCH

THE NEW SCHOOL

To the Editor of THE LANCET

SIR,—Controversy, above all with an old friend, is distasteful to me, there is something more to be said, but this shall be my last word.

It seems I was wrong in my definition of the "old" and "new" schools, it is not that the old is the clinical, and the new school that which armed with the new and powerful methods of polygraph, X rays electro-cardiogram, and so forth has recently laid us under lasting obligations Sir James Mackenzie retorts that "it is the hospital and laboratory workers" (the physiologists and pathologists) that blind" as they are, have "dominated the profession" and given themselves insufferable airs These are the "old" school The new school, as with some candour he gives us to understand, is Sir James Mackenzie himself. As such, he declares, for instance, that "the medical profession" took up "recruiting, utterly unconscious of the fact that they did not possess the necessary knowledge" "Had the Royal College of Physicians itself taken up the duty" (i e, every Member and Fellow except, of course, Sir James Mackenzie himself) "the same disastrous results would have followed because the necessary knowledge does not exist" (though the *new school is not* without some good notion of it). Alas! this accusation is but too true We all unless always for one of us, are far indeed from any certain and comprehensive understanding of that last and crowning miracle of creation, the human body We have been, it is true, modestly thankful that we had penetrated a little way, and learned something, in two thousand years, but we are chastened by the verdict of the new school that our meddling with recruiting has been "disastrous" Not that the medical officers engaged, consisting of persons of various skill and experience, occupied on an unwonted task of enormous difficulty, and driven under terrific pressure, have made mistakes this interpretation would be too generous to them, they would have been better away, their interference has been simply disastrous." Their fault was sheer "ignorance of the amount of work a man in impaired health is capable of undertaking" Why, let us take a simpler case In a girder of a bridge a flaw is found out accidentally—a flaw subject to stresses frosts, and rust The engineer is ordered to state definitely "the amount of work that impaired girder (still *in situ*) is capable of undertaking As the girder is "failing" all the time he can but say that if Baldwin locomotives weighing 400 tons with trucks of like capacity are sent over the bridge at speeds of 60 miles an hour it will collapse pretty soon, but that if light loads and low speeds be enforced well, it may last ever so long But the engineer then will appear as stupid and incompetent as the "old school" physician

We were told that we blundered because we "cannot grasp the (new) movement and "the significance of principles, we cannot search rightly (as the new school does) for the mechanism by which a symptom is produced nor calculate the ultimate effect of the primary fault. Now, to meet the new school I set out after my antique manner one or two only of the more important of these very principles in order to interpret this very "mechanism Above all things surely the heart is a pump and the circulation a hydraulic system I quoted therefore one or two of the elementary hydraulic principles fundamentally implied such as the cross sections of chambers and tubes and the behaviour of viscous fluids in linear or turbulent motion with the respective losses of kinetic energy and so forth, plain laws of dynamics taught in all our schools That they were correctly set out and of no far-spun or academic character but in this matter of immediate and fundamental importance I have since been assured by two or three distinguished physicists and physiologists What is the comment of the new school on my answer to its own demand Sir James Mackenzie says "I frankly confess I don t understand him and refrain from criticising"! The new school "frankly" is indifferent to the elementary laws of the functions of the pump and vascular system of whose "mechanism" it contemptuously asserts that its opponents are stupidly ignorant

Again, Sir James Mackenzie has "searched the writings" of home and foreign authors, and "failed completely to get from any of them a clear description of what is meant by heart failure No wonder, by no literary ingenuity can so loose and colloquial a phrase be made to stand upright or to support any precise argument He pays me the compliment of saying that he has thus searched even my poor essays and in vain I am writing now away from all books, my own or other, but if Sir James Mackenzie will look again into my *Diseases of Arteries* (Vol II) he will find that in my opinion to say a man died of heart failure is about as precise as the old saw that "he died of shortness of breath" No engineer would use "girder failure" as a technical term

While scoffing at us for inattention to the origins of maladies, Sir James Mackenzie himself still hovers only over the final phases of a cardiac fault one, it may be, of long standing, when a local has begun to extend itself into a more general disturbance In his last letter he repeats that the first sign to be looked for is a "sensation" "Every genuine sensation" he says (what is a non genuine sensation?) "has a physical cause in its production" (e g palpitation, exhaustion, &c.) Is "physical" exclusive of psychical? If not, we are left with the information that every sensation is caused, no very bright illumination But it is in part this very psychical element which makes "effort tests" so fallible, until, indeed, "sensations" begin to stare us in the face without their help Sir James Mackenzie adds that "long before physical signs are evident the patient is conscious that something is amiss" This is the sort of proposition that the new school lays down—a vague proposition as often wrong as right One longs for a quarter of an hour of the Socratic method with the new school. As to the paragraph on palpitation, if its content is valuable to the new school, the old school to a man will cheerfully do without it I am not writing flippantly Sir James Mackenzie is a very able man and has no doubt profounder meanings in his mind. I criticise, and can criticise, only what is written

For farther illumination Sir James Mackenzie leaves the heart for gastric ulcer of which, it seems, we are as ignorant as we are of heart diseases Again he twits me personally with "ignorance of the cause and nature of heartburn"—a term surely even as loose as "heart failure" itself Old women and others use it in various senses, but generally to signify, not regurgitation of the cleaner acid of the gastric juice, often in excess in gastric ulcer, but rather of the acrid products of the butyric fermentation, not a very abstruse process However, in gastric ulcer "heartburn is not a characteristic nor a very common feature—not, that is, in the ordinary use of the word The proper pain of gastric ulcer arises when the peritoneal covering of the viscus is affected, as Dr Hugh Anderson has explained.

Furthermore, Sir James Mackenzie writes "The elementary knowledge for understanding pain is not yet known to the profession We even do not know what tissues are capable of producing pain" This assertion reminds me of that in the previous letter which declared that no careful attempts had ever been made to study the behaviour of the heart in pregnancy I then pointed out that on the contrary a great deal of particularly careful work had been devoted to this very subject and now I note that this subject is silently dropped—with the "innocent murmurs" But I gladly testify that in this field, before the "new school began Sir James Mackenzie had done some early, original and promising work work which I believe he has laid aside for other disquisitions, but that merit cannot justify his lofty indifference to the no less valuable work of others in the sensory field such as that of Dogiel Henry Head H K Anderson Mott and many another fellow neurologist Dr Anderson indeed has precisely demonstrated the very tissue which is asked for—namely that in which visceral or other pains have their origin and seat[1] I fear Sir James Mackenzie may again "frankly confess his ignorance of these researches but it is such isolation which allows an author to write without a blush "No physician in the past had any conception of how to bring to light the information behind a patient's sensations, nor knew how to set about acquiring that information "! "No physician in the past", that is, until the new school arose!

---

[1] I am sorry that being away from home I cannot give the reference but I have quoted his researches in my "Diseases of the Arteries"

I have animadverted more than once on the looseness of the terms and phrases of the new school a looseness which betrays a like habit of dealing with thought, evidence, and doctrine In a grave peroration Sir James Mackenzie after advising the younger teachers not to lean on authority but to use their own faculties of observation and reason—a very salutary lesson but one which Sir James Mackenzie must have borrowed from the "old school"—appeals to them farther as follows "Before you teach your students a simple fact, verify it from your personal experience, or search in the writings of your authorities for their reasons in making a statement" A "fact" is rather demonstrated than taught, alone it teaches nothing, nor is a fact a "statement", nor again in the fact alone, uncoördinated with other facts, are there any reasons A fact is no more a rational "statement" than a brick is a house It is this lack of precision in terms in the new school which gives rise to much misunderstanding And I am sorry to note a less excusable error Sir James Mackenzie chides me for refusing for life insurance two brothers, otherwise eligible, on account of occasional extrasystoles in both Now against this reading I had explicitly guarded myself by this clause—"or rather for stating the facts that led to their refusal' I well remember—for the coincidence was a curious one—telling these men that I had advised acceptance It may surprise Sir James Mackenzie to hear that thirty or forty years ago the nature and significance of extrasystoles, thanks to observations of Burdon Sanderson, B W Richardson, Balfour, and many other physicians of the time, were as well, or as little, understood by the old school as they are now by the new

Finally, Sir James Mackenzie knows I hope, that no one has a greater respect for his work, and personal regard for himself than I have We, all of us owe much to him If to my regret I shall have seemed to say anything inconsistent with this regard it is out of my regard for other men and other things also I am, Sir, yours faithfully,

CLIFFORD ALLBUTT

Ullswater Hotel Patterdale Westmorland August 26th 1917

PS —In your issue of Sept 1st is an interesting letter by Dr E W Adams on the question of the adequacy of language to thought That new thoughts may need new language or new readaptations of it, is true, but our first duty is to see that we use in a precise manner such language and terms as we possess

To the Editor of THE LANCET

SIR,—Two years' experience of cardiac work at a base overseas has shown that the question a medical officer has most often to answer in a "heart" case is a practical one "Is the man 'fit' or 'unfit' for active service?' The "effort test" by Army physical drill as recommended by the workers at the Military Hospital at Hampstead, was utilised to aid in answering this important question During the whole of this experience the question of the clinical significance of a systolic murmur at the apex of the heart was constantly under consideration The difficulty of estimating the myocardial efficiency by the response to effort, under circumstances where men may, *even unconsciously*, exaggerate their complaints, increases the complexity of the problem

Sir Clifford Allbutt in his letter to THE LANCET of Aug 4th, which purports to represent the "old" school begs the question by discussing "endocardial murmurs" The assessment of the importance of a systolic murmur is only possible when we know the cause to which it is due To describe a bruit as an endocardial murmur in no way explains the pathology of its origin The teaching of Mackenzie that we should endeavour to ascertain the real cause of any murmur heard, is always illustrated by his conception of the cardiac complications of rheumatic fever Here the student in the "new" school learns the cause to be an infective process, often of slow progression, as demonstrated by the study of the infected individual throughout the rest of his life It becomes difficult to *disentangle "old"* and "new' school ideas, but together they represent the tide of scientific progress A study with the continuity of observation that Sir James Mackenzie desires of the soil," as represented by the infected patient, must bear fruit equally with the researches that are conducted upon the "seed" The more so as to-day the clinical side of the study of many chronic infective processes is just as difficult and obscure as is their bacteriological aspect

I am, Sir, yours faithfully,

JOHN E MACILWAINE

College gardens Belfast August 17th 1917

THE GENESIS OF PHOBIAS IN CHILDHOOD

To the Editor of THE LANCET

SIR,—In your issue of August 18th Captain W H R Rivers has recorded very fully an interesting case of claustrophobia By careful direction of the thoughts of the sufferer, the remembrance of a certain terrifying incident in his childhood was regained As a little child he had been shut up in a closed space, unable to escape the attentions of a growling dog *A complete cure followed* when the tardy recollection of this incident had provided the explanation of the origin of the phobia I suppose it is possible that in the sensitive mind of a child a single severe shock of this kind may produce effects which persist long after the recollection of the incident has faded from memory I have had a patient, 50 years of age, who from fear of falling had never been able to go down stairs without holding on to the banisters In his case, however, family tradition assigned the infirmity to a fall in early childhood, and since he had long accepted this explanation, though without recollection of it himself, I was unable to exercise 'psycho analysis' or effect a cure by a demonstration of the causative incident.

Whether such forgotten experiences are or are not a common cause of neuroses I do not pretend to say but I think that everyone who is a student of childhood as well as of Freudism, in determining the cause of a phobia, would lay the greater stress, not upon any one shocking or terrifying experience, but upon the unwise attitude of parents and nurses in focussing the child's attention upon the fear in sapping his confidence by showing their own apprehensions and communicating them to the suggestible child The child *of himself is not afraid to* fall It is the parents who make him afraid by treating the fall as a disaster The child of himself is not afraid of being left alone It is the parents who undermine his confidence by keeping him always under observation from a nameless dread of what may happen to him

Captain Rivers s analysis of his case of claustrophobia ignores this all important point The malign influence was doubtless here a too great solicitude for an ailing child An atmosphere of unrest and apprehension in the nursery exerts a depressing influence upon the mental equilibrium, the physical constitution, and the whole vitality of the child, and this influence is exerted not on a single occasion only, but throughout all the years of childhood The restoring of the incident to memory and the subsequent freedom from *symptoms indicate no more* than that the extreme suggestibility which was his undoing during an ill managed childhood is still to be found in the patient If this sufferer from claustrophobia had had full recollection of the incident, or if the family had persistently repeated the story to him, would his own study of the teaching of Freud, which we are told had been close have sufficed to effect a cure without the stimulating influence of Captain Rivers s personality? I think not —I am, Sir, yours faithfully,

H CHARLES CAMERON

London, W, August 28th 1917

THE RELATION OF TRENCH FEVER TO OTHER CONDITIONS

To the Editor of THE LANCET

SIR,—The following preliminary statement on the relations existing between trench fever, 'P U O," myalgia, 'rheumatism," 'influenza" 'D A H" (or "soldier s heart") and other obscure conditions accounting for an enormous percentage of the morbidity in the British Armies, appears to us to be of sufficient interest to be brought at once to the notice of the profession The observations on which our conclusions are based were carried out on a large number of cases grouped as indicated above We submit —

1 That it is of the utmost importance to search carefully for the sources of toxin which may have precipitated breakdown in this group of cases

2. That trench fever is a source of toxin in these conditions which cannot safely be ignored

3 That many of the cases diagnosed as "pyrexia of uncertain origin" (P U O), myalgia, "rheumatism," "influenza,' should really be recognised as cases of trench fever

4 That the trench fever infection is far more persistent than has been generally supposed, and that, as a consequence, its sequelæ are more widespread and important than has been recognised

5 That hyperalgesic areas of skin and muscle are commonly met with in cases having a history of trench fever, "P U O ," myalgia, 'rheumatism," influenza " and also malaria, and that the same areas exist in many cases of D A.H., or 'soldier s heart," who may not be able to give a definite history of trench fever at the time of observation, but who, nevertheless, on exposure to undue effort, not infrequently develop a slight remitting temperature and other symptoms indicative of trench fever

Disordered action of the heart (D A.H) in the soldier is now by some observers recognised as a clinical entity, but the condition may, nevertheless, conceivably result in the large majority of instances from one of many forms of intoxication or infection. The importance of leaving no effort unexpended to identify the specific toxin in each instance has not, perhaps, been fully admitted The impairment of physical capacity has been carefully estimated, the classification of patients by their response to graduated exercise has been instituted as a reliable guide to the medical officer, but what remains to be done is to show that, granted intoxication or infection as a cause, a sound treatment must be based on the recognition and subsequent elimination of the toxin which caused the damage

Our observations on the above enumerated conditions seem to us to support the view that intoxication or infection underlies D A.H , and are therefore submitted for publication in the hope that the future investigation of the condition may be along the lines of a broader inquiry into the causes of intoxication rather than in further estimation of its effects

The recent work of one of our number Captain Dimond in his recognition of the organism associated with trench fever illustrates what we mean, and if the remaining sources of intoxication or infection whether in the blood lungs kidneys or alimentary tract could be similarly isolated by special workers we would be safe in assuming that a prognosis could, in most cases be arrived at and prophylactic measures and treatment materially advanced

We hope at an early date to publish a more complete statement upon our findings

We are Sir yours faithfully,
W BYAM, Major R A.M.C Officer in Charge Medical Division
LYN DIMOND Captain, R.A.M C
V E SORAPURE Captain, R A M C
R M WILSON Lieutenant R A.M.C

*** A communication on the subject of trench fever from Captain Lyn Dimond appears in another part of our present issue —ED L

PSYCHIATRY IN ENGLAND

To the Editor of THE LANCET

SIR,—Everyone with any experience of the treatment of mental and nervous breakdown must have read your leading article on The Effect of the War upon Psychiatry in England with the deepest interest. Shell shock cases and other mental disturbances caused by the war must have individual rather than general treatment and as these cases are in the large majority purely functional it is manifestly clear that they require encouragement happy environment and people to be with them to distract their minds in various ways gain their confidence and assure them that they will soon be quite themselves again The excellent book you mention by Professor G Elliot Smith and Mr T H Pear does not to my mind instil into our minds the necessity for well chosen companions or nurses to help in their treatment and too much stress is laid upon the physician s help It is absolutely wicked to send many of these cases to asylums, although I have known of some few cases where such limitations were necessary and where they could not safely be supervised anywhere else especially cases with a definite impulsive suicidal tendency

With some 44 years of experience in lunacy the matter is one that greatly appeals to me For the first 14 years of my medical life I dealt considerably with borderland cases, and many of these were saved from the necessity of certification For the next 20 years I was superintendent of a fairly large private asylum while during the last 10 years I have treated large numbers of borderland cases, and have seen very many mental cases in consultation That the present lunacy laws are a great handicap to early treatment is a matter too well known to need discussion, though I admit that the Board of Control are taking a much less decidedly old fashioned way of dealing with many cases and thus making it easier for experienced psychologists to deal with early mental cases without the fear of legal prosecution against those who receive these cases One great fact which has never been satisfactorily cleared up is the standing reproach that with our palatial institutions for the insane, and with our great increase in pathological research, the recovery rate of insanity is no higher to-day in these institutions than it was in the decade of 1865 to 1875

I have been in correspondence with many mental physicians and with the Lunacy Board of Scotland, in which country far more clinical work is carried out than is the case in England, and yet the recovery rate is still *in statu quo*, and I have not yet been able to come to any definite conclusion as to the cause of this deplorable fact It may be due to many causes (1) the legal restrictions, which make the proper early treatment so difficult, (2) the want of individual study of the character, temperament and causes which have led to the mental breakdown, and (3) perhaps the most important of all causes, the want of proper departmentisation of cases in asylums This last cause has been brought home to me in many cases Patients have been sent to institutions with the danger mark of suicidal *tendency*, and with this stigma they have been placed at once on the side of the asylum with the worst cases, because there, and there only, can constant supervision be easily and economically carried out I have known mild cases of this sort which have been rendered much worse by being herded together with severe mental patients to their definite detriment. In the asylum I presided over I made a point of this departmentisation with very good results, while some of my patients who lived with my family hardly realised that they were in an asylum, and I could give the history of the recovery of many of such cases Then, again I fear we do not employ sufficient lady and gentleman companions who if well trained, have such a beneficial effect upon many patients

It is certainly the fact that many general practitioners are now getting into touch with mental cases caused by shell shock and nervous disturbance and gaining a considerable experience but we still have many busy medical men who in their own words cannot be bothered with mental cases and have no spare time to give to looking after them, ' and are only too glad to get them off their books

I am, Sir, yours faithfully,
Bournemouth Sept 3rd 1917 L A. WEATHERLY, M D

INFANT MORTALITY AT VILLIERS-LE-DUC

To the Editor of THE LANCET

SIR,—In your annotation in THE LANCET of Sept 1st relating to the report on infant mortality issued by the Commonwealth Committee on Death and Invalidity you say that the report refers to the scheme enforced by the Municipality of Villiers le-Duc which it claims has simply abolished the death rate of infants The same claim was made in a recent Milroy lecture I have not seen the Commonwealth report but it is difficult to believe that its authors were aware of the extreme smallness of the data upon which these conclusions are based The experience of *Villiers le-Duc has* been widely boomed by social reformers, but in none of the accounts which I have seen have the actual figures been quoted—merely the death *rates* The following are the facts —

	Total births	Deaths	Infant mortality rate.
1892-1903	54	0	0
1903-1915	43	4	93

Taking the two periods together we have a rate of 41 deaths per 1000 births which is about equal to the average of Connaught and much of the west of Ireland and many healthy English rural districts

Of course, no one with even an elementary knowledge of statistics would draw inferences from such wholly insufficient material, and to work out infant mortality rates per 1000 births on an average of less than 6 births per annum is the acme of absurdity Yet this has been done in several of the published accounts of the Villiers le Duc scheme in order to show the effects of regulations

I am, Sir, yours faithfully,
WILLIAM A BREND

Barmouth North Wales Sept 2nd 1917

CAUTION IN GRANTING MEDICAL CERTIFICATES

To the Editor of THE LANCET

SIR,—Inasmuch as one of the daily duties of consultants just now is the granting of medical certificates to men who anticipate being called up on military service, it has occurred to me that in order to prevent the possibility of personation by unscrupulous people it is wise to get the examinee to write his signature in one's presence on the certificate given him Otherwise the unfortunate consultant might find himself figuring at a later period in a criminal trial !

I am, Sir, yours faithfully,
Wimpole-street W, August 29th 1917 DAN MCKENZIE

Obituary.

ARTHUR EDWARD PATTERSON, M D ABERD

Dr A E Patterson, who died on August 26th after a short illness, was senior assistant medical officer to the City of London Mental Hospital, Dartford Son of the late Major D A Patterson, he received the whole of his education in Aberdeen, graduating M B, C M at the University in 1885 After a short period of general practice he became assistant medical officer to the Derby Borough Asylum, and was later appointed to the City of London Mental Hospital A conscientious and painstaking officer, his cheery manner and true kindness of heart made him popular amongst staff and patients alike He was an active member of the Medico Psychological Association, and published several articles, of which the most important was "An Analysis of 1000 Admissions into the City of London Asylum," in the *Journal of Mental Science*

Medical News.

MEDICAL OFFICERSHIP OF BATH —The post of medical officer of health for the city of Bath, rendered vacant by the death of Dr W H Symons, will be temporarily filled for the duration of the war and six months afterwards by Mr C A G Collins, the medical officer of the Bath Statutory Hospital It was felt by the sanitary authority of the city that, with so many potential candidates serving in the war, it would have been unfair to have advertised a permanent appointment, a view with which Mr Collins has stated himself to be in accord

MEASLES AND RESEARCH —At the last meeting of the Sanitary Committee of the Manchester Corporation the following resolution was passed —

> That in view of the frequently recurring outbreaks of measles on an extensive scale throughout the country and the mortality among young children occasioned thereby this council urges upon the Government the desirability of setting aside a sum of money for research work into the causation of this disease and the best means of securing its prevention

A copy of the resolution has been forwarded to the President of the Local Government Board

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index)

When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor

APPLECROSS PARISH COUNCIL.—Medical Officer and Public Vaccinator for the Torridon District Salary £150 per annum with house, &c

BELFAST MUNICIPAL SANATORIUM Whiteabbey —Lady Superintendent (Temporary) Salary at rate of £120 per annum with rations &c

BIRKENHEAD BOROUGH HOSPITAL —Junior House Surgeon Salary £175 per annum with board &c.

BIRKENHEAD UNION INFIRMARY —Junior Female Resident Assistant Medical Officer Salary at rate of £300 per annum with board &c.

BOLTON INFIRMARY —Female Locum Tenens Assistant House Surgeon

BRISTOL ROYAL INFIRMARY —House Physician and House Surgeon. Salary at rate of £120 per annum with board &c

BURY INFIRMARY —Junior House Surgeon Salary £150 per annum with board &c

CARLISLE CUMBERLAND INFIRMARY —Female House Surgeon for six months Salary at rate of £250 per annum with board &c. Also Female House Physician for six months. Salary at rate of £200 per annum with board &c

STOCKPORT INFIRMARY —Senior House Surgeon Salary £250 per annum with board &c

WEST LONDON HOSPITAL Hammersmith W —House Surgeon Salary £4 4s weekly with board, &c

WIGAN ROYAL ALBERT EDWARD INFIRMARY —Junior House Surgeon Salary £200 per annum with board &c

THE Chief Inspector of Factories, Home Office, London S W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Littleborough (Lancaster) and Wotton under Edge (Gloucester)

Births, Marriages, and Deaths.

BIRTHS

DAUNT —On August 19th in Edinburgh the wife of Captain Francis Eldon Daunt M B B S Lond R A M C of a daughter

ORAM —On August 31st, at Ridgemount, Anerley Park, S E the wife of Capt Alger Roy Oram M B B Ch B A O N U I R A M C of a daughter

ROXBURGH —On August 30th at Belgrave crescent Edinburgh the wife of Temp Surgeon Archibald Cathcart Roxburgh, M B B C Camb R N of a son

WADMORE —On August 28th at Clifton Bristol the wife of Captain Wadmore R A M C, of a son

MARRIAGES

HEARN—COOLING —On Sept 3rd at the Hampstead Parish Church Captain Reginald John Hearn L M S S A Lond R A M C to Winifred Maud younger daughter of Mr and Mrs Cooling of Hampstead

HIGGINS–INGRAM —On August 29th at the Parish Church Congleton Cheshire by the Rev Thomas Twistington Higgins M A father of the bridegroom assisted by the Rev Charles Edward Sullivan M A vicar of Hulme Walfield Thomas Twistington Higgins F R C S Captain R A M C to Jessie younger daughter of Thomas Ingram B A of Melrose, Scotland

WRIGHT—LOWENFELD —On August 25th at the Chapel Royal Savoy Henry Wardel Snarey Wright M R C S Eng L R C P Lond Captain R A M C to Helena Rosa Lowenfeld M B B S Lond of Great Cumberland place London

DEATHS

ATKINSON —On Sept 1st, at Saffron Walden John Parkinson Atkinson M D Glasg L R C P Lond L R C S Ed J P aged 79

FIELDING —On August 31st at Bethel street Norwich James Fielding M D Vict Univ Canada L R C P Edin M R C S Eng of The Crescent Norwich

GRIFFITH WILLIAMS —On Sept. 1st at Mattishall William Henry Griffith Williams L R C P L R C S Edin

HORA —On August 31st at his residence Hazel Brae Filsham Park St Leonards-on Sea Mr James Hora Vice-President of the London Hospital and treasurer of Westminster Hospital late of Victoria street Westminster S W aged 91

LAVER.—On August 31st at 43 Head-street, Colchester Alderman Henry Laver, J P M R C S, F S A in his 88th year Funeral Tuesday Sept 4th St. Mary at the Walls Church Colchester

N B —A fee of 5s is charged for the insertion of Notices of Births Marriages and Deaths

Notes, Short Comments, and Answers to Correspondents.

HEALTH AND HOSPITALS IN HONG KONG

A REPORT on the Blue book of Hong Kong for the year 1916 has just been presented through the Colonial Office to the Houses of Parliament It states, *inter alia* that the civil population of the colony, according to the Census taken in 1911, was 456,739, of whom 104,287 resided in the New Territories and in New Kowloon, at the Census taken in 1906 it was 301,967 exclusive of the New Territories and of New Kowloon The estimated total population at the middle of the year under review was 528 010, but this includes the New Territories, and, as the birth and death figures given below do not include those from this area (*with the exception of New Kowloon*), the population for the purposes of calculating these rates is estimated at 431,510, of whom 13,390 were non Chinese

The corrected birth rate for the year was 8 1 per 1000 among the Chinese community and 23·05 per 1000 among the non Chinese community as compared with 8 4 and 13 2 during 1915 The death rate for the year was 24·6 per 1000 among the Chinese community and 15·03 among the non Chinese *community*, as compared with 19 0 and 9 4 during 1915 The number of deaths from malaria (378) showed an increase on the previous year (356) The deaths of Chinese *from* this cause in the city of Victoria numbered 162 out of a population of 270 300 or a rate of 0·6 per 1000 per annum The deaths from plague numbered 39 as compared with 144 in 1915 Small pox deaths numbered 542, all Chinese with the exception of three British and one each American Portuguese, and Indian There were 2112 deaths *from* respiratory diseases among the Chinese as compared with 2313 in 1915 Pulmonary tuberculosis and phthisis claimed 963 Chinese victims while other forms of tuberculosis *represent* an additional 554 deaths, making a total of 1517 or 14 4 per cent of the grand total of deaths among that community Beri beri was *responsible* for 517 deaths as compared with 393 during 1915 and 333 in 1914 During the past few years circulars have been distributed *to* all large employers of coolie labour calling their attention to the fact that beri beri is produced by the consumption of white rice as the staple article of diet without a sufficiency of other foods and advising that beans should be supplied with the rice when fresh *meat* or *fresh* fish cannot be afforded

The Civil Hospital at Hong Kong *contains* 150 beds in 19 wards In it 3063 in patients and 12 620 out patients were treated during 1916 as against 3065 and 14 159 respectively in 1915 360 cases of malarial fever were admitted as against 364 in 1915 and 324 in 1914 but the total cases of malaria for all Government *hospitals* and the Tung Wa Hospital showed an increase of 684 cases as compared with the year 1915 At Kennedy Town Infectious Diseases Hospital which contains 26 beds 30 cases were treated *in 1916* all being small pox The lunatic asylum is under the direction of the superintendent of the civil hospital European and Chinese patients are separated the European portion containing 8 *beds* in separate wards, and the Chinese portion 16 beds 237 patients of all races were treated during 1916 and there were 6 deaths The *Tung Wa Hospital* opened in 1872, is *mainly* supported by the voluntary subscriptions of Chinese but receives an annual grant of 8000 dollars from the *Government* Only Chinese are *treated in* this institution Chinese as well as European methods of treatment are employed in accordance with the wishes expressed by the patients or their friends about half the *number* are now treated by Western methods It is under the supervision of a visiting physician who is a member of the medical department whilst two Chinese house *surgeons*, trained in Western medicine are members of the hospital staff There are 323 beds in the buildings and 5150 patients were accommodated during 1916 *The Tung Wa* also maintain a *branch* hospital for small pox cases (Chinese only) at Kennedy Town It contains 58 beds, and during 1916 171 cases were treated The Alice Memorial and Affiliated *Hospitals* are managed and controlled by the missionaries resident in Hong Kong agents *of* the London Missionary Society and consist of the Alice Memorial Hospital opened in 1887 the Nethersole Hospital opened in 1893 the Alice Memorial Maternity Hospital opened in 1904 and the Ho Miu Ling Hospital opened in 1906 The number of in patients in 1915 was 1731 the number of labours in the Maternity Hospital was 450

To avoid the complete seclusion from friends and relatives which removal of Chinese plague patients to the Kennedy Town Infectious Diseases Hospital entailed four district plague hospitals are now maintained by the Chinese in various parts of the colony These are under the management of the same committee as are the Chinese public dispensaries These dispensaries eight in number are maintained by voluntary subscriptions in order to provide the Chinese with the services of doctors whose certificates will be accepted by the registrar of deaths and with the services of interpreters who can [illegible] the inmates of houses where cases of infectious diseases occur Coolies are engaged and ambulances and dead vans provided in order to remove cases of infectious disease to the Infectious Diseases Hospital and dead bodies to the mortuary The dispensaries also receive infants and send them to one or other of the convents and arrange for the burial of dead infants Free advice and medicine are given and patients are [illegible] at their houses The Kwong Wa Hospital for Chinese in the Kowloon Peninsula contains [illegible] patients were accommodated during 1916 One [illegible] in the colony [illegible] supported by [illegible] founded under the will of the late Mr Granville Sharp and [illegible] British American and [illegible] accommodation [illegible] three [illegible] a main [illegible] for [illegible] block [illegible] during [illegible] the main building

The mean shade temperature for the year at the Royal Observatory Kowloon (108 feet above mean sea level) was 71 8° 0 4° lower than the mean for the past 10 years The total rainfall for the year was 79 855 inches as compared with an average of 82 56 inches during the 10 preceding years

One of the most notable events of the year in Hong Kong was the first Congregation of the University, which was held on Dec. 14th, when honorary degrees were conferred on, amongst others, Sir Robert Ho Tung, a merchant of Hong Kong, the founder of a chair of clinical surgery in the University, Dr Wu Lien Teh, who, after a brilliant career at Cambridge and in medical schools in England and on the continent, has done much useful work in China, including the stamping out of the plague epidemic in North Manchuria in 1910–11, and several graduates in the Faculty of Medicine At the end of the year the number of students taking the course in medicine at the University was 52 The University is composed of three faculties—Medical, Arts and Engineering The medical offers ample facilities for the practice of medicine The anatomical laboratories were the gift of a Cantonese gentleman, Mr Ng Li hing There is a large staff of instructors in medicine and all the principal medical practitioners in Hong Kong give lectures at the University

INTRAMUSCULAR GALYL

Messrs The Anglo French Drug Company, Limited, of Gamage Building Holborn, London, E C 1, point out in regard to our analytical notice of this preparation in our issue last week that the capacity of the ampoule was stated to be 15 cubic centimetres, whereas the volume of fluid is 2 cubic centimetres, containing 15 centigrammes of galyl

---

N I Z—All writers on medical jurisprudence agree that the giving of a second certificate of death is inadvisable There is no statute expressly forbidding a medical practitioner to do so but apparently there are provisions annulling the value of any certificate other than the one first given These provisions had their origin in a praiseworthy attempt to prevent the over insurance of children A section in the Friendly Societies Act, 1875 prohibits a registrar of deaths giving a certificate for an insured child unless the cause of death has been entered in the register on the certificate of a coroner or of a registered medical practitioner The issue of two medical certificates might place the registrar in a difficult position

Medical Diary for the ensuing Week.

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR" and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention should be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, *and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification*

Letters whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Offices 423, STRAND, LONDON W C 2.

MANAGER'S NOTICES

VOLUMES AND CASES

VOLUMES for the first half of the year 1917 are now ready Bound in cloth, gilt lettered, price 21s , carriage extra

Cases for binding the half year's numbers (inland edition) are also ready Cloth, gilt lettered, price 2s 6d , by post 2s 10d

To be obtained on application to the Manager, accompanied by remittance

TO COLONIAL AND FOREIGN SUBSCRIBERS.

Subscribers abroad are particularly requested to note the rates of subscriptions given on page 4

The Manager will be pleased to forward copies direct from the Offices to places abroad at the rates shown, whatever be the weight of any of the copies so supplied

FOURTH

Analysis

OF

CASES OF TETANUS TREATED IN HOME MILITARY HOSPITALS

DURING PART OF OCTOBER NOVEMBER, AND PART OF DECEMBER, 1916

By Sir DAVID BRUCE, C B, F R S, F R C P,
SURGEON GENERAL, ARMY MEDICAL SERVICE.

THREE analyses of cases of tetanus treated in home hospitals have been published in THE LANCET—one on Oct 23rd, 1915 the second on Dec 2nd, 1916, and the third on June 30th, 1917

In the third analysis it was stated that the intention was to publish each series of 100 cases as they occurred, and the present paper deals with the first 100 cases completed since the last analysis was written The number of cases of tetanus dealt with in the four periods and the rate of mortality are given in Table I —

TABLE I.

Analyses	No of cases	Recovered	Died.	Mortality per cent
1914-15	231	98	133	57·7
1915-16	195	99	96	49·2
Aug -Oct 1916.	200	127	73	36·5
Oct -Dec. 1916	100	69	31	31·0

It is satisfactory to see that the rate of mortality is steadily going down

THE DISTRIBUTION OF CASES OF TETANUS FROM AUGUST, 1914, TO DECEMBER, 1916

Diagram 1 merely represents the number of cases of tetanus which have been treated in home military hospitals since the beginning of the war They are taken from the date of the wound not from the date of onset of the disease. For example in August 1914 there were five men wounded who sooner or later developed tetanus The figures have no relation to the number of wounded or the number of troops engaged It shows periods of activity and inactivity in the fighting line

Diagram 2 represents the number of cases of tetanus which have been treated in home military hospitals since the beginning of the war They are taken from the date of the onset of the disease For example in August 1914 there were two wounded men in England who had been attacked by tetanus

THE NUMBER OF CASES OF TETANUS OCCURRING AMONG WOUNDED SOLDIERS

Diagram 3 represents the ratio of cases of tetanus to the number of wounded soldiers treated in home military hospitals from August 1914 to December 1916 It will be seen that the ratio in September 1914 is about six times as high as in November 1914 and that it remains at the lower level until the end of 1916 This fall in the ratio is undoubtedly to a great extent due to the introduction of prophylactic injections of antitetanic serum which took place about the middle of October

RELATION OF THE NUMBER OF DAYS WHICH ELAPSED BETWEEN THE DATE OF WOUND AND THE ONSET OF SYMPTOMS AND THE RATE OF MORTALITY

Diagram 4 shows that in the 100 cases dealt with, if the symptoms of tetanus appeared within 10 days of receiving the wound the mortality was 83 3 per cent , if between the eleventh and twenty fourth day 29 6 per cent The remaining 57 cases with an incubation period of from 25 to 100 days 16 per cent The shorter the incubation period the greater the rate of mortality the longer the incubation period the smaller the rate of mortality

No 4907

DIAGRAM 1.

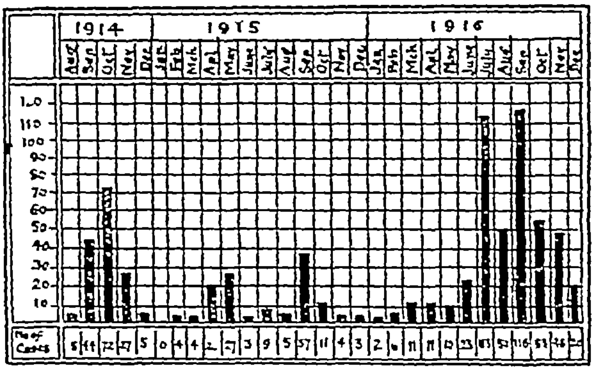

DIAGRAM 2

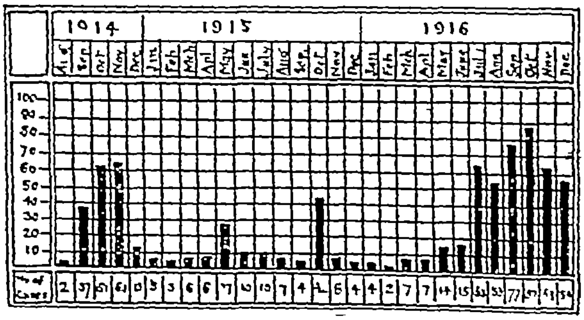

DIAGRAM 3

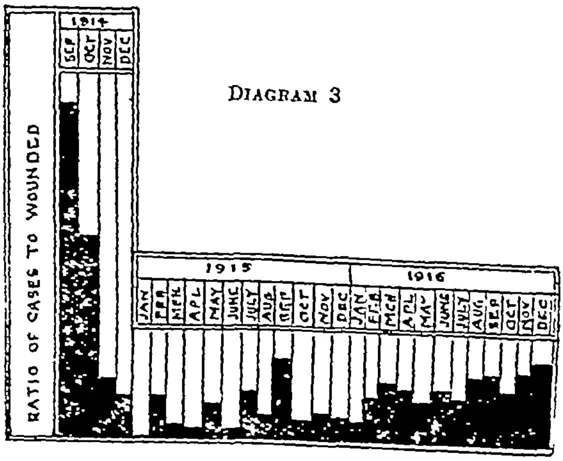

DIAGRAM 4

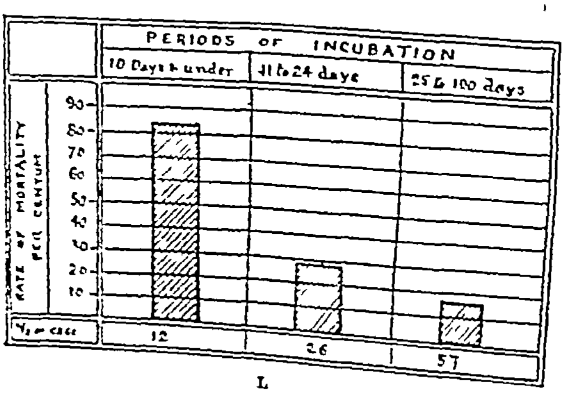
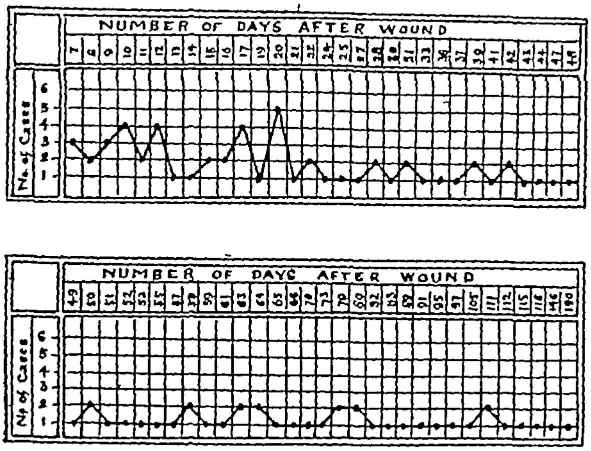


THE INCUBATION PERIOD, OR NUMBER OF DAYS WHICH ELAPSE BETWEEN THE DATE OF WOUND AND THE ONSET OF TETANUS SYMPTOMS

CURVE A



Curve A shows the number of cases which occurred on each day after the date of the wound. The shortest period of incubation was seven days, the longest 190 Only 95 out of the 100 cases are recorded, the incubation period in the remaining 5 not being given in their reports There were only 12 cases with a short incubation period—that is, up to 10 days, and 60 cases with an incubation period of more than 22 days

THE VARIATION IN THE PERIOD OF INCUBATION SINCE THE BEGINNING OF THE WAR

The following table gives the number, in percentages, of cases of tetanus with short, medium, and long incubation periods which have occurred since the beginning of the war From it will be seen that in the first year there were 47 per cent of cases with a short incubation, whereas in the last analysis this has fallen to 12 6 per cent. In 1914–15 there were only 6 4 per cent of cases with a long incubation period, this rose at the end of 1916 to 61 1 per cent

TABLE II.—*Incubation Periods*

Analyses.	Up to 10 days per cent.	11 to 22 days, per cent	More than 22 days, per cent.
1914–15	47·0	46·4	6·4
1915–16	15·5	48 8	35·6
Aug to Oct, 1916	14·0	43 8	42 1
Oct to Dec, 1916	12·6	26 3	61 1

This is a measure of the action of the prophylactic inoculation of antitoxin. During the first year of the war many of the wounded did not receive this, hence the number of acute cases with a short incubation

THE PROPORTION OF CASES OF LOCAL TETANUS TO GENERAL TETANUS

It is by no means easy in many cases to decide whether a case is one of generalised or localised tetanus By generalised tetanus is meant the occurrence of spasticity or rigidity in muscles distant from the site of wound Trismus is the most common initial symptom in general tetanus

In local tetanus the spasticity or rigidity is confined to the muscles in the neighbourhood of the wound In a case of this kind arising, for example, from a wound of the right leg the toxin may be pictured as passing up the nerves and affecting the motor cells of the cord which regulate the nervous supply to the muscles of the wounded leg In these cases the toxin does not appear to proceed farther up the cord or to be capable of spreading by the blood stream Hence the symptoms of twitching, spasm, or rigidity are confined to the wounded limb Local tetanus may be looked upon as a much modified variety of the original disease, or even as a new type, due to the action of the prophylactic injection of antitoxin

In general tetanus, on the other hand, the toxin molecules may be pictured as gaining entrance to the circulation and so reaching all parts of the nervous system In this case trismus is frequently the first symptom either on account of some selective quality towards the toxin inherent in the fifth nerve or on account of the shortness of the nervous route between the masseter muscles and the central nervous system

On examining the 100 cases under consideration it was found that 61 could be placed in the general and 28 in the local group In 11 it was doubtful to which group they belonged or if the cause of death was tetanus In the 61 cases of generalised tetanus there were 40 recoveries and 21 deaths, a mortality of 34 4 per cent All the cases of localised tetanus recovered The symptom of trismus is recorded in 54 out of the 61 cases, opisthotonos in 17 The following table gives this in tabular form —

TABLE III

Cases	Type of tetanus	Recovered	Died.	Mortality, per cent
61	General	40	21	34·4
28	Local	28	0	0·0
11	Doubtful	1	10	91·0

THE POSITION OF THE WOUNDS IN REFERENCE TO THE MORTALITY

TABLE IV

Position of wounds	No of cases.	Recovered.	Died	Mortality per cent.
Body	38	24	14	36·8
Limbs	62	45	17	27·4

Among these were nine cases of trench feet, seven of whom died. Also a case following appendicitis and one following an operation for hæmorrhoids

THE EFFECT OF FRACTURES ON THE RATE OF MORTALITY IN CASES OF TETANUS

TABLE V

Wound.	No of cases	Recovered.	Died	Mortality per cent.
Fractures ..	35	31	4	11·4
No fracture	65	38	27	41·5

In the previous, or third, analysis the percentage of wounds with fracture of one or more bones was 36, with a rate of mortality of 30 1 per cent It is difficult to understand why this fall in the rate of mortality to 11·4 per cent has taken place

TETANUS OCCURRING AFTER OPERATIVE INTERFERENCE WITH THE WOUND

TABLE VI.

No of case.	Date of wound	Date of operation	Date of tetanus	Days after wound	Days after operation	Nature of wound	Nature of operation	Recovered	Died
	1916	1916	1916						
637	12–8	30–10	9–11	89	10	Fract r thigh	Amputation.	—	D
550	28–8	3–11	10–11	82	7	Fract. l thigh leg & l. elbow	Passive movement of elbow	R	—
611	14–11	23–11	25–11	11	2	Wound of calf	Vein ligatured.	—	D
620	7–11	22–11	23–11	15	1	Behind l ear and elbow	Removal of bullet near 2nd cerv vertebra	—	D
647	12–10	25–10	8–11	27	14	R leg & foot	Re-amputation	R	—
656	6–10	17–10	23–10	17	6	R arm & hand.	Removal of metal from thumb	R	—
631	28–9	15–11	22–11	55	7	Back, l. leg and knee.	Swelling opened in r flank	–	D
663	18–8	?	7–12	111	?	Fracture both thighs, scrotum & forearm	Fell against bed on old injury wounds healed	—	D
669	18–9	14–10	31–10	43	17	R scapula, 2 wounds l. arm	Shrapnel removed from shoulder	R	—
672	28–9	7–12	10–12	73	3	Foot and ankle.	Shrapnel removed from ankle	R	—
673	?–3	5–10	8–10	over 190	3	Thigh	4 pieces of metal removed	—	D
674	5–11	24–11	25–11	20	1	R buttock	Shrapnel removed	R	—
698	5–10	7–11	20–11	44	13	Fract. l leg	Amputation.	R	—
737	9–8	17–11	29–11	112	12	R thigh	Metal removed	R	—
751	13–11	28–11	29–11	16	1	R heel	Pieces of sock and boot removed	R	—

Table VI gives the cases, 15 in all, in which tetanus is reported to have followed on an operation. There were 6 deaths, a mortality of 40 per cent In only 2 of these cases was a prophylactic inoculation given before the operation The Tetanus Committee advise that when operations are performed at the site of wounds, even if they are healed, a prophylactic injection of serum should invariably be given

ON OPERATIVE INTERFERENCE AFTER TETANUS SYMPTOMS HAVE APPEARED

TABLE VII

No of case	Date of tetanus	Date of operation	Days after onset	Nature of wound	Nature of operation	Recovered
61	15-9-16	16-9-16	1	Fract face and l arm	Bone from arm and jaw removed	R
62	4-12-16	8-12-16	4	Fracture of humerus	Sequestrum removed.	R

Table VII gives the cases, 2 in all, in which an operation was carried out on the wound after the appearance of symptoms of tetanus There were two recoveries Since the beginning of the war 52 cases of this kind have been reported, with a mortality of 40 per cent

The opinion of the Tetanus Committee is that it appears to be safer to abstain from surgical interference with the wound until the ordinary treatment for tetanus has been carried out, unless there exist other and imperative reasons for immediate operation When the symptoms of tetanus have subsided and the tissues are flooded with antitoxin, then the wound can be opened up and searched for foreign bodies or hidden collections of pus and tetanus bacilli

TREATMENT OF TETANUS BY ANTITETANIC SERUM

A. *Prophylactic or Preventive Treatment*

Among the 100 cases 61 are noted as having received a prophylactic injection of antitetanic serum in France. Ten cases are reported to have received secondary prophylactic injections in home hospitals It is evident that the recommendations of the Tetanus Committee regarding these secondary injections were only beginning to bear a promise of fruit at the end of 1916 Of these 61 cases 51 recovered and 10 died giving a mortality of 16·4 per cent Of the remaining 39 cases there is no record of prophylactic treatment in 22 although in all probability many of them received it Of these 22 12 recovered and 10 died—a mortality of 40 5 per cent The remaining 17 cases are stated to have had no prophylactic injection of any kind Of these 6 recovered and 11 died—a mortality of 64 7 per cent This may be represented shortly in the following table which also gives the results since the beginning of the war —

TABLE VIII

Prophylactic injections	Rate of mortality per cent			
	1914-15	1915-16	Aug to Oct 1916	Oct to Dec. 1916
Received	51 3	42 8	27·[illegible]	16·4
Not recorded	41 1	52·0	44·8	40·5
None given	62 5	55 5	[illegible]5	64 7

In regard to the question as to what influence if any promptitude in giving these prophylactic injections has in reducing mortality the following table gives all the available information —

TABLE IX

No of cases	Inoculated	Recovered	Died	Mortality per cent
42	On day of wound	35	7	16·6
9	One day after wound	7	2	22·2
7	Two days	7	0	—
1	Four „	0	1	—
2	More than four days	2	0	—

Of the 42 cases inoculated on day of wound the average incubation period was 48 days Of the 17 cases which are reported to have received no prophylactic inoculation the average incubation was 14 3 days.

ON THE RESULTS OBTAINED FROM MULTIPLE PROPHYLACTIC INJECTIONS.

The Tetanus Committee have laid down that four prophylactic injections should be given to every wounded soldier at intervals of seven days In the 100 cases under review the case mortality was 31 per cent It will be remembered that only 61 out of the 100 cases were recorded as having received a prophylactic injection in France

The following table represents the rate of mortality of cases of tetanus which have received one to four prophylactic injections From this table it would appear that one prophylactic inoculation is more potent than two, three, or four, but the numbers are small

TABLE X

Number of inoculations.	No of cases.	Recovered	Died	Mortality per cent
Received one	37	33	4	10·8
„ two	18	14	4	22·2
„ three.	5	3	2	40·0
„ four	1	1	0	0·0

Table XI represents the effect of one inoculation or more on the incubation period.

TABLE XI

Number of inoculations	No of cases	Average incubation period in days.
1	37	49·3
2	18	38 7
3	5	73·[illegible]
4	1	70·0

B *Therapeutic or Curative Treatment*

Out of the total of 100 cases the number treated with antitetanic serum after the onset of symptoms was 98 Two cases did not receive therapeutic treatment with antitetanic serum in England, 1 recovered 1 died The patient who recovered is reported to have had a prophylactic injection on day of wound, of the one who died there is no record. The man who recovered showed symptoms of tetanus after an incubation of 63 days, he had opisthotonos but no trismus The symptoms lasted for three days He was treated with nux vomica and strychnia. There is no reason given for his not having received specific treatment The man who died showed symptoms of tetanus on Nov 5th and died four days afterwards Very few details are given in his tetanus report but it is evident that antitetanic serum was not given owing to failure to diagnose the disease in time. On Oct. 30th an amputation of the affected leg was performed but no prophylactic injection was given at the time It is evident that in these two cases the recommendations of the Tetanus Committee were not followed.

Of the 98 cases which received serum treatment 68 recovered and 30 died Mortality 30·6 per cent

ON THE INFLUENCE OF ROUTE IN THE INJECTION OF ANTITETANIC SERUM

The Tetanus Committee in their Memorandum are of opinion "that in acute general tetanus the best method of treatment lies in the earliest possible administration of large doses of antitoxin serum by the intrathecal route." Of the 98 cases—

	Mortality per cent
3 were treated by subcutaneous injections alone 2 recovered 1 died ...	33 3
10 were treated by intramuscular injections alone 8 recovered 2 died ...	20·0
1 was treated by intravenous injection alone 1 recovered ...	0·0
2 were treated by intrathecal injections alone 2 died	100·0
There were 75 cases which included intrathecal injections 49 recovered 26 died ...	34·6
There were 23 cases which did not receive intrathecal injections 19 recovered 4 died ...	17 4
There were 15 cases which included intravenous injections 13 recovered, 2 died ...	13 3
There were 83 cases which did not include intravenous injections 55 recovered 28 died ...	33 7

It would appear from the above table that no advantage in favour of intrathecal injections emerges from the figures, as seemed to be the case in 1914–15 The numbers are too small, but are given in order to make the different analyses comparable. It must also be noted that it is the severe cases which are treated by the intrathecal route, the slight cases by the intramuscular or subcutaneous As is shown elsewhere, cases of localised tetanus tend strongly to recovery, and it is in these cases that intramuscular injections are given It is, in fact, so laid down in the Memorandum on Tetanus "In the *chronic forms of tetanus*, particularly the form of localised tetanus limited to one limb, without trismus or other sign of generalisation, there appears to be no need to resort to intrathecal injection A course of serum treatment by the intramuscular method will, in most cases, do all that is required."

It may be thought that an apology to the reader is demanded for bringing up figures that prove nothing But it may be urged that the same figures give information of some kind or another, for example, it is shown that in the latter part of the year 1916 98 per cent of cases of tetanus were treated in England by antitoxic serum, and in 75 per cent the serum was inoculated intrathecally This is of some interest to-day and may be of more interest in the future

IS THERE ANY OTHER EVIDENCE TO BE FOUND IN THE TETANUS REPORTS THAT THE INTRATHECAL ROUTE HAS ANY ADVANTAGE OVER THE OTHER METHODS OF INJECTION?

Treatment Beginning on Day of Onset of Disease	Mortality per cent.
During the period October–December, 1916 57 cases were treated with antitetanic serum on the day the symptoms declared themselves 34 recovered 23 died ..	40 3
Out of the 57 cases the following received antitoxin but not intrathecally on the day of the disease 26 cases 18 recovered 8 died	30 7
Out of the 57 cases the following received antitoxin, including intrathecally on the day of onset of the disease. 31 cases: 16 recovered, 15 died	48 4
Treatment Beginning on the Day following the Onset of Disease	
During this period 12 cases were treated with antitetanic serum beginning one day after the symptoms had declared themselves 11 recovered 1 died	8 3
Out of the 12 cases the following received antitoxin but not intrathecally one day after the onset of the disease 10 cases 9 recovered 1 died ..	10·0
Out of the 12 cases the following received antitoxin including intrathecally, one day after the onset of the disease 2 cases: 2 recovered ...	0 0
Treatment Beginning Two Days after the Onset of the Disease	
During this period 8 cases were treated with antitetanic serum beginning two days after the symptoms had declared themselves 6 recovered 2 died ..	25·0
Out of the 8 cases the following received antitoxin but not intrathecally, two days after the onset of the disease 2 cases: 2 recovered	0·0
Out of the 8 cases the following received antitoxin including intrathecally two days after the onset of the disease 6 cases 4 recovered 2 died ..	33 3
Treatment Beginning Three to Eight Days after the Onset of the Disease	
During the same period 21 cases were treated with antitetanic serum beginning three to eight days after the symptoms had declared themselves 17 recovered 4 died ..	19·0
Of the 21 cases the following received antitoxin but not intrathecally, three to eight days after the onset of the disease 11 cases: 10 recovered, 1 died	9 0
Of the 21 cases the following received antitoxin, including intrathecally three to eight days after the onset of the disease 10 cases: 7 recovered 3 died ..	30·0

It is evident that no case either for or against the intrathecal route can be made out from these figures and again, as in the last analysis, it would appear better to defer treatment for one or more days after the onset of the disease This probably only means that the severe cases are treated at once, the less severe are dallied with

THE INFLUENCE OF DOSAGE ON THE CURATIVE ACTION OF ANTITETANIC SERUM

(a) The Total Quantity of Antitoxin Given During the Attack

Out of the 98 cases—

		Recovered.	Died	Mortality per cent.
0 received	1 000 units or under	2	0	0·0
2 "	1 001 to 5 000 units	4	4	50 0
8 "	5 001 " 10 000 "	7	2	22 2
9 "	10 001 " 15 000 "	7	2	0·0
5 "	15 001 " 20 000 "	5	0	0·0
15 "	20 001 " 30 000 "	8	7	46 0
12 "	30 001 " 40,000 "	8	4	33 3
19 "	40 001 " 60 000 "	12	7	36 8
21 "	60 001 " 100 000 "	16	5	23·8
7 "	100,001 " 249 000 "	6	1	14·2

(b) The Daily Quantity of Antitoxin Given

Out of the 98 cases—

1 received	1 000 units or under	1	—	0·0
31 "	1 001 " 5 000 units	29	2	6 4
33 "	5 001 " 10 001 "	21	12	36 3
22 "	10 001 " 20 000 "	13	9	40·9
7 "	20 001 " 30 000 "	2	5	71 4
3 "	30 001 " 40 000 "	1	2	66 6
1 "	40 001 " 52,000 "	—	1	100·0

From these figures relating to dosage no useful deduction can be made They may be useful to enable a comparison to be made with the amount of serum given at different periods during the war

OTHER THERAPEUTIC REMEDIES

During this period no cases were treated with carbolic acid injections or magnesium sulphate

CONCLUSIONS

1 In the 100 cases of tetanus under review the mortality was 31 per cent

2 The ratio of the number of cases of tetanus to the wounded has fallen greatly since the beginning of the war due in all probability to a great extent to the introduction of prophylactic injections of antitetanic serum

3 The incubation period *tends to become longer*, hence there are only 12 cases reported with an incubation of 10 days or under

4 Only 10 cases are reported to have received secondary prophylactic injections of antitetanic serum in home hospitals

5 In regard to the therapeutic effect of antitoxic serum the evidence is still inconclusive.

6 The rate of mortality in generalised tetanus is 34 4 per cent, in localised tetanus 0 0 per cent

WAR NEPHRITIS

BY C E SUNDELL, M D LOND, M R C P LOND,
TEMPORARY CAPTAIN R.A.M.C.
AND
A T NANKIVELL, M D LOND, D P H CAMB,
TEMPORARY CAPTAIN R.A.M.C.

THIS communication is based upon the study of 250 cases of nephritis which have come under the personal treatment or supervision of one of us (C E S) and upon the pathological investigation of the last 50 of these (A. T N) The figures quoted below refer to 160 of those cases whose records are available

It is proposed to deal with the subject under the headings of Clinical Aspects and Pathology, and to review the various work which has been done upon its etiology

Clinical Aspects

Seasonal incidence —Our own cases reached their maximum in the months of January and February This is contrary to the observations of other writers and is probably to be explained by an increase in the military population from which this hospital draws its sick, during these months divisional units were "resting" in the neighbourhood

Age incidence —The average age of our last 160 patients was 31 years The disease was commonest in the decade 25 to 35, 8 per cent of the cases, in which a history of previous disease could be excluded, occurred over the age of 40

Previous renal disease —A history of this could rarely be obtained Of 160 cases, 6 *certainly* and 2 probably had suffered from a previous attack of nephritis Of these, 2 gave a history of nephritis while on active service, one six months, the other 12 months previously, 4 had had acute nephritis in civil life, 2 gave histories of scarlet fever with delayed convalescence within the preceding five years

Nature of the duties on which the patients were employed — Of our 160 cases 10 per cent had never been in the front line, while the remainder had all served at the front, in many cases such service had been discontinued for a period of weeks or months before the onset of nephritis Three of our 250 cases occurred in officers The average stay in France of our last 80 cases was 7½ months, 5 cases occurred before the fourth month

Associated conditions —Some degree of bronchitis was a constant feature, it was often a serious complication, and in two of the fatal cases was responsible for death Septic infection of the skin in the form of impetigo or a superficial wound was present in 12 of our cases Trench foot was present in two cases Quinsy preceded the onset of nephritis by five days in one case (Contrast Citron [9])

Type of case —There are all varieties in the severity of the disease, ranging from the slight attack with little or no œdema to the typical and fatal case It seems possible that slight atypical or abortive cases, who suffer from an undiagnosed malaise, may recover without admission to hospital

Mode of onset —The appearance of the more striking symptoms is so impressive that it is only occasionally that the patient volunteers the statement that he had been indisposed for any time before he was compelled to "go sick." Careful inquiry will, however, in a large majority of instances elicit the information that there has been some departure from the normal health for two or three days before the onset of the acute symptoms. Such slight prodromal symptoms include headache backache, "a cold," and a feeling of fatigue after slight exertion, some degree of bronchial catarrh is practically constant at this stage Alimentary symptoms are rarely mentioned, and it is unusual for complaint to be made of any alteration of urine or micturition during the prodromal period, but some patients speak of "scalding" as having occurred from the very commencement of the illness The following symptoms and signs are found in every typical case œdema *dyspnœa, headache* Very common, but not invariable, are backache, limb-pains, slight pyrexia, and scanty micturition Probably if these patients came under observation at the earliest stage of the disease these symptoms would be more often in evidence

Œdema —This always affects the face, it may be confined to this situation or involve the whole body The positions in which it is found are, in order of frequency, face, feet, hands, lumbar region, scrotum, and abdominal wall Ascites and pleural effusions are uncommon except in those patients in whom the disease tends to run a prolonged course The duration of the œdema is very variable—usually it disappears rapidly, if the case is not seen during the first three or four days it may already be entirely absent, we have seen it disappear completely within 36 hours of the onset Associated with the œdema an almost characteristic flush of the skin is often seen, it is not a cyanosis but a red flush resembling early sunburn In our experience this appearance has been most noticeable in patients suffering from capillary bronchitis

Dyspnœa —Some degree of respiratory distress is constant Most of the patients describe the onset as quite sudden, the man may parade in full marching order without discomfort, and fall out a few minutes later, quite unable to march after the column has gone a few hundred yards Many of the men however when closely questioned, state that they have noticed gradually increasing shortness of breath for two or three days before the occurrence of the dramatic attack In a large proportion of cases this shortness of breath, slight and gradual or sudden and severe, may precede the appearance of facial œdema by several days When at rest the condition is one of hurried respiration rather than a true dyspnœa It lasts for several days and may persist after the disappearance of œdema Cheyne Stokes *respiration* is not seen except in conditions of severe uræmia. Urgent respiratory distress while the patient is at rest *may* occur if the disease is complicated by severe bronchitis or as a manifestation of uræmia Two of our seven deaths were due to sudden uræmic dyspnœa

Headache —All our patients suffered from dull headache, most commonly frontal often occipital rarely vertical This is one of the earliest symptoms and is often of long duration An increase in its severity has been noted as a herald of uræmia. We were unable to demonstrate a definite relationship between the degree of the headache and systolic blood pressure Its disappearance is accompanied by a sense of well being which cannot in our opinion be entirely due to the relief from a moderate though persistent pain

Cough —All our patients suffered to some extent from cough often accompanied by a considerable amount of expectoration the sputum being usually frothy and liquid, except in those cases which were complicated by purulent bronchitis

Backache —This is practically constant, rarely severe, it persists for several days It is localised to the loin, and does not radiate, it is variously described as a dull ache, a weight or a load on the loins

Abdominal pain is occasionally complained of, in our experience chiefly in those patients who suffer from uræmic symptoms It is transient and variable in intensity and position

Limb-pains —These are common but transient Nothing approaching in severity or persistence the "shin pains" of trench fever has been met with. This point is of some clinical importance, for in many cases of trench fever albuminuria occurs during the first few days The limb pains of nephritis are present only in the early stage of the disease, they disappear with the return of the temperature to normal

Urine —In the first days oliguria or suppression is the rule—this is usually of a few days' duration only, and is frequently followed by polyuria which persists after all obvious œdema has disappeared Frequency and scalding are not uncommon during the first few days Incontinence of urine in non-comatose patients occurred in two cases in our series This symptom has been noted by a German observer In 250 cases true dysuria with hypogastric and penile pain was present, these may have been "lower tract" affections as described by Abercrombie [5] They recovered without special medication

Albuminuria is constant at first but may be remarkably transient, it has a tendency to vary from day to day irrespective of diet changes No information as to its ultimate persistence is given by the cases of our series, for they were too short a time under observation

Hæmaturia —Naked eye examination reveals the presence of blood in rather less than half the cases Its amount is even more variable than the albumin, but it may be most persistent The microscopical characters of the urine are described under the heading of "Pathology"

Temperature —Moderate pyrexia for a few days is the rule its duration is brief and relapse uncommon In the presence of associated disease, such as sepsis or severe bronchitis, the pyrexia is more definite and sustained, but with these exceptions war nephritis may, after the few days at the onset be regarded as an afebrile disease

Pulse —The pulse rate is little altered It may rise to 90 or 100 and remain at this figure for a week or 10 days, but persistent tachycardia has been a very rare symptom In two cases it occurred without any other apparent cause

Blood pressure —The hæmodynamometer was not used in all cases and experience has convinced us of the fallacy of relying upon digital impressions in estimating blood pressure The highest record obtained was 210 mm. this was met with in a uræmic case in the presence of which complication readings of 150–180 were not uncommon In mild and quiescent cases no striking rise of blood pressure was met with

Eye changes —Captain R Graham Brown, R A.M C, kindly reported upon 35 consecutive cases The fundus was normal in 29, while in 6 slight blurring of a portion of the disc margin or papillœdema was present All these patients had facial œdema The retinal change and the facial œdema appeared to clear up at the same time No case was under observation at a sufficiently late stage for chronic changes to be manifest. Transient blindness occurred in 2 cases as one of several uræmic symptoms Difficulty in reading was complained of by a few patients early in the disease, and some of these had slight blurring of the disc, but it is doubtful whether this disability could not be explained by general causes

Complications —Only two serious complications were met with—bronchitis and uræmia The importance of the former is very great and its presence has a very adverse influence upon prognosis.

Uræmia is seen in about 8 *per cent* of the cases Its onset is usually early in the disease, it may afford the first manifestation In only 2 cases of our 160 did it occur after the tenth day The common manifestations of uræmia are torpor severe headache nausea, vomiting (always to be regarded as a danger signal) and convulsions Uræmic convulsions in this disease present several interesting features They come on with very little warning, they are very violent, they usually occur quite early in the course of the illness and paradoxical as it may seem are to be regarded on clinical experience as of good prognosis provided they are not fatal within the first few hours Our experience has been that those patients who have had severe uræmic convulsions calling for active measures and causing considerable alarm have, after a few days of semi coma, passed on rapidly towards almost complete recovery, their albuminuria has ceased, the flow of urine has been re established, and there has been a speedy return of a sense of well being Chronic uræmia, giving rise to a prolonged state of cheerful busy delirium bordering on mania, occurred in two cases who ultimately returned to apparently normal mental health

Treatment

Treatment has been mainly expectant or aimed at the removal of complications as they arose Diuretics were rarely used and seemed of no value Diaphoretics were employed in a few cases, but it is doubtful whether they had any influence on the course of the disease It is remarkable how these patients sweat without drug treatment It is the exception to find the skin dry after the first few days Hot packs were rarely used, they seemed of doubtful benefit and, by adding to risk of chill, a real danger Fluids were not restricted, but the patients were not encouraged to drink more than they desired No attempt to wash out nitrogenous material by flushing the system was made A reason for avoiding copious drinks is the effect which the intake of large quantities of fluid has upon the blood pressure Purgation was used, but was never drastic Calomel gr iii at night followed by a saline purge in the morning was the routine Occasionally an enema was employed at the commencement of the treatment

All cases were kept for three days at least on a rigid milk diet Three pints per diem were allowed After this time, if the albumin showed signs of diminishing, if blood was no longer visible to the naked eye in the urine, if the quantity of urine was normal, if the blood pressure was not raised, and if headache was not troublesome an increase in the diet was allowed—toast, biscuits, a flavouring of tea in the milk, rice milk (a fluid form of rice pudding made without eggs) In no case did the patient's condition call for a return to strict milk diet

While uræmic danger signs were present the strict milk diet was enforced The treatment of uræmia followed the usual lines—venesection, intravenous infusion of saline, and lumbar puncture The last operation is of the greatest benefit, it is necessary to perform it under chloroform anæsthesia on account of the uncontrolled movement of the patient, the removal of six or seven drachms of fluid is followed by a striking improvement The fluid is usually under slightly increased pressure, but it is possible that this is due to the anæsthesia

Opium in the form of morphia or omnopon was given freely and with benefit in uræmic cases, its diaphoretic effect was very noticeable

In the chronic form of excitement bromide, even in large doses, had little or no effect, opium had to be substituted

Prognosis

Our observation of these cases has been too short to allow any opinion as to their ultimate prognosis to be formed but certain points bearing on their immediate prognosis have been noted The coexistence of a severe degree of bronchitis is of bad omen, four cases died and the partial recovery of others was delayed greatly The coexistence of sepsis did not seem to have any adverse influence The presence of uræmic symptoms varied in significance The cases that showed great sleepiness during the first few days did as well as those who did not show this sign Uræmic convulsions, as has already been noted, if not immediately fatal, were shown by experience of several cases to be of good prognosis Persisting mental changes, which may be regarded as uræmic in origin, however, were associated with persistence of albuminuria and hæmaturia long after the normal date for their disappearance The blood pressure in the early stages gave little guidance Some patients with a systolic pressure of 180 mm Hg made as rapid a recovery as those in whom the pressure was not raised As a herald of approaching uræmia sustained high blood pressure may be regarded as of importance Pressure-readings during or immediately after a convulsion are probably of little value as they must be influenced by the muscular exertion involved in the seizure As no patient was allowed to get up before his evacuation from this hospital no information is available as to the possible return of albuminuria in non albuminous cases after apparent recovery and on the resumption of the erect posture Temporary increase of the albumin occurs commonly in cases still confined to bed without change in general symptoms and appears to be independent of changes in the diet

Pathology

The urines from 50 cases of war nephritis have been examined since February of this year Concurrently with these, 44 urines, both from normal individuals and from men who were patients in hospital, have been examined as a control

All cases of war nephritis showed casts in the urine. The casts were hyaline, granular, fatty and blood, the first two being the most common As would be expected, the more definite the clinical symptoms the larger was the number of casts Again, all cases of war nephritis showed the presence of many degenerate endothelial cells in pronounced distinction to urines obtained from men suffering with other illnes es where endothelial cells were few or absent. The presence of casts and of endothelial cells is, in our opinion, sufficient microscopical evidence on which to diagnose this form of nephritis The endothelial cells are of all shapes and sizes, but are most commonly spherical, varying from about 10μ to 35 or 40μ They show vacuoles, one or more nuclei, and are invariably granular in appearance They are in all stages of degeneration Occasionally one has been seen to bud, and it is common to find one bursting open and the intracellular protoplasm being distributed into the surrounding fluid It seems to us that these cells may be similar to the "amœba urinata granulata," described by other writers [1 2] They have never shown any true amœboid movement, however, and are exactly similar in appearance to endothelial cells from pleural effusions or to those found in the fæces in chronic cases of dysentery They stain well in moist preparations, especially if the urine sediment has previously been washed in distilled water As has been said, their presence in the urine of cases of war nephritis is invariable, nor are they found in any number in other conditions We had two cases, however, of injury in the loin, where although the kidney was not damaged microscopically endothelial cells were found in the urine These were, no doubt due to the fact that the kidney substance was disturbed by the force of the original wound shock or by toxin absorption from the wound This was confirmed by microscopical examination in one case

In mild cases of war nephritis a few only of such degenerate cells will be found in the centrifugalised deposit of the urine In a serious case many may be found in each field of the microscope (objective 6 X eyepiece) One of our cases who at first showed no definite clinical signs gave no endothelial cells in the urine, but as his symptoms of nephritis developed the endothelial cells appeared These bodies persist in the urine after the patient is apparently well—even when the urine shows no casts, and perhaps they may be of value not only in the diagnosis of a doubtful case, but also in determining whether a man has had war nephritis in the past How long they persist *we are at present unable to say*

Thirty six out of these 50 cases showed red blood corpuscles in the urine The amount of blood did not appear to indicate the severity of the attack. One of our most serious cases had very little, other clinically mild cases showed much blood The determination of the presence of red blood corpuscles was made microscopically on the centrifugalised deposit of a fresh specimen

Twenty two men had albumin in the urine, and the urines of the remainder—28—failed to give the nitric acid or boiling test for albumin

A few red blood cells a few casts, and endothelial cells in a low specific gravity urine would hardly be sufficient to give a definite and appreciable chemical test and here we would like to urge the importance of examining microscopically the *centrifugalised deposit of urine*, since in the absence of this definite examination it would be possible to miss many slight atypical or convalescent cases Renal tubule cells and cells from the renal pelvis, in all stages of degeneration were found in 9 cases out of the 50 Leucocytes, more in number than could be accounted for by the blood in the urine, were present in 3 cases

Of the series of negative cases taken concurrently with those of war nephritis, none showed either casts, or more than a very few endothelial cells Five had albuminuria, 1, who was possibly suffering from a renal calculus, showed renal pelvis cells, 5 had blood in the urine, 4 showed excess oxalates, and 7 had leucocytes Of these 44 cases 7 had definite inflammation of the urinary tract, without, however, the endothelial cells found in the nephritis cases

No cultural results were obtained aerobically or anaerobically—either from the urines or from two cases whose venous blood was examined

Blood films were made and differentially counted in 15 cases with the following results Small mononuclears ranged from 16 to 30 per cent, with an average of 22 2 per cent, large mononuclears from 8 to 18 per cent, with an average of 13 3 per cent, finely granular polymorphonuclear leucocytes ranged from 47 to 69 per cent, with an average of 62 1 per cent, and eosinophiles were from 1 to 5 per cent., with an average of 2 4 per cent "Mast" cells were not counted differentially, but were present frequently No myelocytes were observed Basophiles were found occasionally No obvious change was noted in the red cells and no parasites were observed The blood counts individually were typical of the so-called protozoal blood count with large mononuclear increase, and in addition to this most of the cases showed a slight eosinophile increase Citron[6] in his cases records an eosinophilia up to 10 per cent

Two specimens of the cerebro-spinal fluid from cases of uræmia were examined One was apparently a normal fluid, the other showed excess of small mononuclear cells and contained 0·022 per cent of urea Aerobic and anaerobic cultures failed to isolate any pathogenic organism Only one case of war nephritis has died out of this series of 50 At the post mortem the kidney was found apparently normal and not appreciably enlarged—it certainly was not the enlarged and œdematous kidney of ordinary acute nephritis, and showed no intense engorgement such as is found in early scarlatinal nephritis No macroscopic changes were evident Parts of one kidney *were fixed in formalin* 10 per cent and mounted in paraffin Sections were cut of these and were specially stained and examined for micro-organisms and for protozoa None, however, were observed Sections stained with hæmatoxylin and *eosin showed* the following points of interest The nephritis was irregular in distribution, parts of the kidney seemed absolutely normal—one field, for example, showed healthy kidney tissue, and yet the field next to it showed definite evidence of disease The nephritis is both tubular and glomerular Many of the glomeruli were almost entirely destroyed or swollen and degenerate and filled with endothelial plugs The cells lining Bowman's capsule showed almost equal destruction, as did the cells of the convoluted and straight tubules Some of these latter were found filled with casts Between the glomeruli and among the tubules were patches of interstitial hæmorrhage The smaller arterioles in the affected parts of the kidney showed endarteritis. The nephritis was, in other words focal and not diffuse This has also been observed by Pick.[4]

Of the total number of our clinical cases (250 in all) there were seven deaths A post mortem examination was made on each of these although, with the exception of the case described above, no microscopical investigation of material was possible, in the absence at that time of laboratory facilities The most striking feature was the small departure from normal in the naked eye appearance of the kidneys Four cases had suffered from severe intercurrent purulent bronchitis with consequent circulatory embarrassment No case showed evidence of chronic renal disease Patchy pallor of the cortex was noticed in two cases Moderate enlargement was seen in one case the others showed no macroscopic changes except *for* slight blurring of the cortical structure in one case These patients had died between the fourth and seventeenth day of illness

Ætiology.

It is proposed shortly to consider the various hypotheses that have been advanced on the etiology of war nephritis and to discuss the validity of each

Damp, cold, and exposure have been suggested by many writers as predisposing causes or even as the immediate causative agents of nephritis Hirsch at the Austro German Medical Congress at Warsaw,[2] Pick,[3] and others lay special stress on this exposure theory During the Franco Prussian War, in which a German authority states that there was much nephritis, it is interesting to note that the chief fighting took place in wet weather But against this we have the incidence in the American Civil War, 1861–63, when the cases were most frequent in the summer months Again, Rose Bradford[5] notes that cases were few in the British Expeditionary Force until March and April, 1915, and that their incidence in the summer of that year was especially high Taken together, all these conflicting observations do not favour the supposition that damp, cold, and exposure are essential epidemiological factors

Forced marches have been suggested as a possible cause by Th Rumpel[6] Certainly prolonged fatigue may produce albuminuria, but this is only transitory, and there is no evidence that this passing albuminuria predisposes to disease at a later date As a predisposition to renal disease it is as unlikely a factor as a surfeit of green apples is a factor in the cause of mucous colitis Typical war nephritis occurs among people who have been subject to no excessive muscular fatigue—e g, hospital nurses and orderlies and patients convalescing from some other disease and from injury

Streptococcal tonsillitis was suggested by Citron[7] as a cause We find no incidence of this, nor does Abercrombie in his paper[8] give any support to this hypothesis A few of our cases, but a few only, had a streptococcal infection—viz, impetigo, but the majority did not show this

Singer[9] considers that dysentery is a predisposing factor, and also that protective inoculation against enteric fever may lead to a stirring up of other organisms which had hitherto been quiescent No other writer has, as far as we can learn, considered dysentery to be a factor in the epidemiology of war nephritis, nor do our own cases lend any support to this view Again, there is nothing in the suggestion that inoculation or vaccination predisposes a man to nephritis Troops at home are not affected with nephritis, although they are vaccinated and inoculated against enteric

Lead, arsenic, and zinc have been accused of being the causative agents of this condition They can be ruled out at once The cases do not develop any of the well known symptoms caused by these poisons, and Mackenzie Wallis[10] has been able to show by ultra filtration that the urines of cases of war nephritis do not contain salts of the heavy metals

Thornley claims[11] to have isolated a small Gram negative diplococcus from the blood of cases of war nephritis As far as we can discover, this work has not been confirmed, and our own blood cultures showed no such micro-organisms Mackenzie Wallis[10] *considers that* there are powerfully toxic agents in the urines of cases, and that the organism may be ultra microscopic He has not succeeded in producing the typical disease in animals

That the affection originates in the lung tissue has been suggested by Dunn,[12] who described changes in the lungs similar to those seen in cases of *irritant gas poisoning* It is possible that the pathological changes noted by this observer were the result of the purulent bronchitis, so often a complication, to which attention has been drawn already It seems rather to be an intercurrent affection than to have any causative influence on this disease Exposure to irritant gas could be absolutely excluded in the majority of our own cases

McLeod and Ameuille[13] conclude that the disease is due to deficiency of certain elements in diet and to the consumption of excessive protein They *think that this is the* most likely explanation of transient albuminuria, and that it may contribute towards the development of the more severe cases They are supported by Gaud and Mauriac[14] who consider that fatigue and deficient food elements are the most important factors in the causation of war nephritis

In the face of so many conflicting facts and theories regarding the epidemiology of this disease it may safely be said that the cause is still unknown

The possible infective nature of nephritis is suggested by the following points *there is frequently* a febrile onset, the disease according to Abercrombie relapses in about 2 per cent of cases which is one of the characteristics of protozoal infections, the slightly raised eosinophile count and the marked increase in large mononuclears support this hypothesis regarded on clinical experience as of good prognosis provided they are not fatal within the first few hours Our experience has been that those patients who have had severe uræmic convulsions calling for active measures and causing considerable alarm have, after a few days of semi coma, passed on rapidly towards almost complete recovery, their albuminuria has ceased, the flow of urine has been re-established, and there has been a speedy return of a sense of well being Chronic uræmia, giving rise to a prolonged state of cheerful busy delirium bordering on mania occurred in two cases who ultimately returned to apparently normal mental health

Treatment

Treatment has been mainly expectant or aimed at the removal of complications as they arose Diuretics were rarely used and seemed of no value Diaphoretics were employed in a few cases, but it is doubtful whether they had any influence on the course of the disease It is remarkable how these patients sweat without drug treatment It is the exception to find the skin dry after the first few days. Hot packs were rarely used, they seemed of doubtful benefit and, by adding to risk of chill, a real danger Fluids were not restricted, but the patients were not encouraged to drink more than they desired. No attempt to wash out nitrogenous material by flushing the system was made. A reason for avoiding copious drinks is the effect which the intake of large quantities of fluid has upon the blood pressure Purgation was used, but was never drastic Calomel gr iii at night followed by a saline purge in the morning was the routine Occasionally an enema was employed at the commencement of the treatment

All cases were kept for three days at least on a rigid milk diet Three pints per diem were allowed After this time, if the albumin showed signs of diminishing, if blood was no longer visible to the naked eye in the urine, if the quantity of urine was normal, if the blood pressure was not raised, and if headache was not troublesome an increase in the diet was allowed—toast, biscuits, a flavouring of tea in the milk, rice milk (a fluid form of rice pudding made without eggs) In no case did the patient's condition call for a return to strict milk diet

While uræmic danger signs were present the strict milk diet was enforced The treatment of uræmia followed the usual lines—venesection, intravenous infusion of saline, and lumbar puncture The last operation is of the greatest benefit, it is necessary to perform it under chloroform anæsthesia on account of the uncontrolled movement of the patient, the removal of six or seven drachms of fluid is followed by a striking improvement The fluid is usually under slightly increased pressure, but it is possible that this is due to the anæsthesia

Opium in the form of morphia or omnopon was given freely and with benefit in uræmic cases, its diaphoretic effect was very noticeable

In the chronic form of excitement bromide, even in large doses, had little or no effect, opium had to be substituted

Prognosis

Our observation of these cases has been too short to allow any opinion as to their ultimate prognosis to be formed but certain points bearing on their immediate prognosis have been noted The coexistence of a severe degree of bronchitis is of bad omen, four cases died and the partial recovery of others was delayed greatly The coexistence of sepsis did not seem to have any adverse influence The presence of uræmic symptoms varied in significance The cases that showed great sleepiness during the first few days did as well as those who did not show this sign Uræmic convulsions, as has already been noted, if not immediately fatal, were shown by experience of several cases to be of good prognosis Persisting mental changes, which may be regarded as uræmic in origin however, were associated with persistence of albuminuria and hæmaturia long after the normal date for their disappearance The blood pressure in the early stages gave little guidance Some patients with a systolic pressure of 180 mm Hg made as rapid a recovery as those in whom the pressure was not raised. As a herald of approaching uræmia sustained high blood pressure may be regarded as of importance Pressure readings during or immediately after a convulsion are probably of little value as they must be influenced by the muscular exertion involved in the seizure As no patient was allowed to get up before his evacuation from this hospital no information is available as to the possible return of albuminuria in non albuminous cases after apparent recovery and on the resumption of the erect posture Temporary increase of the albumin occurs commonly in cases still confined to bed without change in general symptoms and appears to be independent of changes in the diet

Pathology

The urines from 50 cases of war nephritis have been examined since February of this year Concurrently with these, 44 urines, both from normal individuals and from men who were patients in hospital, have been examined as a control

All cases of war nephritis showed casts in the urine. The casts were hyaline, granular, fatty and blood, the first two being the most common As would be expected, the more definite the clinical symptoms the larger was the number of casts Again, all cases of war nephritis showed the presence of many degenerate endothelial cells in pronounced distinction to urines obtained from men suffering with other illnesses where endothelial cells were few or absent. The presence of casts and of endothelial cells is, in our opinion, sufficient microscopical evidence on which to diagnose this form of nephritis The endothelial cells are of all shapes and sizes, but are most commonly spherical, varying from about 10μ to 35 or 40μ They show vacuoles, one or more nuclei, and are invariably granular in appearance. They are in all stages of degeneration Occasionally one has been seen to bud, and it is common to find one bursting open and the intracellular protoplasm being distributed into the surrounding fluid It seems to us that these cells may be similar to the "amœba urinata granulata," described by other writers [1, 2] They have never shown any true amœboid movement, however, and are exactly similar in appearance to endothelial cells from pleural effusions or to those found in the fæces in chronic cases of dysentery They stain well in moist preparations, especially if the urine sediment has previously been washed in distilled water As has been said, their presence in the urine of cases of war nephritis is invariable, nor are they found in any number in other conditions We had two cases, however, of injury in the loin, where although the kidney was not damaged microscopically endothelial cells were found in the urine These were, no doubt, due to the fact that the kidney substance was disturbed by the force of the original wound shock or by toxin absorption from the wound This was confirmed by microscopical examination in one case

In mild cases of war nephritis a few only of such degenerate cells will be found in the centrifugalised deposit of the urine In a serious case many may be found in each field of the microscope (objective 6 X eyepiece) One of our cases who at first showed no definite clinical signs gave no endothelial cells in the urine, but as his symptoms of nephritis developed the endothelial cells appeared These bodies persist in the urine after the patient is apparently well—even when the urine shows no casts, and perhaps they may be of value not only in the diagnosis of a doubtful case, but also in determining whether a man has had war nephritis in the past How long they persist we are at present unable to say

Thirty six out of these 50 cases showed red blood corpuscles in the urine The amount of blood did not appear to indicate the severity of the attack. One of our most serious cases had very little, other clinically mild cases showed much blood The determination of the presence of red blood corpuscles was made microscopically on the centrifugalised deposit of a fresh specimen

Twenty two men had albumin in the urine, and the urines of the remainder—28—failed to give the nitric acid or boiling test for albumin

A few red blood cells a few casts, and endothelial cells in a low specific gravity urine would hardly be sufficient to give a definite and appreciable chemical test and here we would like to urge the importance of examining microscopically the centrifugalised deposit of urine, since in the absence of this definite examination it would be possible to miss many slight atypical or convalescent cases Renal tubule cells and cells from the renal pelvis, in all stages of degeneration were found in 9 cases out of the 50 Leucocytes, more in number than could be accounted for by the blood in the urine, were present in 3 cases

Of the series of negative cases taken concurrently with those of war nephritis, none showed either casts, or more than a very few endothelial cells Five had albuminuria, 1, who was possibly suffering from a renal calculus, showed renal pelvis cells, 5 had blood in the urine, 4 showed excess oxalates, and 7 had leucocytes Of these 44 cases 7 had definite inflammation of the urinary tract, without, however, the endothelial cells found in the nephritis cases

No cultural results were obtained aerobically or anaerobically—either from the urines or from two cases whose venous blood was examined

Blood films were made and differentially counted in 15 cases with the following results Small mononuclears ranged from 16 to 30 per cent, with an average of 22 2 per cent, large mononuclears from 8 to 18 per cent, with an average of 13 3 per cent, finely granular polymorphonuclear leucocytes ranged from 47 to 69 per cent, with an average of 62 1 per cent, and eosinophiles were from 1 to 5 per cent., with an average of 2·4 per cent "Mast" cells were not counted differentially, but were present frequently No myelocytes were observed. Basophiles were found occasionally No obvious change was noted in the red cells and no parasites were observed The blood counts individually were typical of the so-called protozoal blood count with large-mononuclear increase, and in addition to this most of the cases showed a slight eosinophile increase Citron[7] in his cases records an eosinophilia up to 10 per cent

Two specimens of the cerebro-spinal fluid from cases of uræmia were examined One was apparently a normal fluid, the other showed excess of small mononuclear cells and contained 0·022 per cent of urea. Aerobic and anaerobic cultures failed to isolate any pathogenic organism Only one case of war nephritis has died out of this series of 50 At the post mortem the kidney was found apparently normal and not appreciably enlarged—it certainly was not the enlarged and œdematous kidney of ordinary acute nephritis, and showed no intense engorgement such as is found in early scarlatinal nephritis No macroscopic changes were evident Parts of one kidney were fixed in formalin 10 per cent and mounted in paraffin Sections were cut of these and were specially stained and examined for micro organisms and for protozoa None, however, were observed Sections stained with hæmatoxylin and eosin showed the following points of interest The nephritis was irregular in distribution, parts of the kidney seemed absolutely normal—one field, for example, showed healthy kidney tissue, and yet the field next to it showed definite evidence of disease The nephritis is both tubular and glomerular Many of the glomeruli were almost entirely destroyed or swollen and degenerate and filled with endothelial plugs The cells lining Bowman's capsule showed almost equal destruction, as did the cells of the convoluted and straight tubules Some of these latter were found filled with casts Between the glomeruli and among the tubules were patches of interstitial hæmorrhage The smaller arterioles in the affected parts of the kidney showed endarteritis The nephritis was, in other words focal and not diffuse This has also been observed by Pick[4]

Of the total number of our clinical cases (250 in all) there were seven deaths A post mortem examination was made on each of these although, with the exception of the case described above, no microscopical investigation of material was possible, in the absence at that time of laboratory facilities The most striking feature was the small departure from normal in the naked eye appearance of the kidneys Four cases had suffered from severe intercurrent purulent bronchitis with consequent circulatory embarrassment No case showed evidence of chronic renal disease Patchy pallor of the cortex was noticed in two cases Moderate enlargement was seen in one case the others showed no macroscopic changes except for slight blurring of the cortical structure in one case These patients had died between the fourth and seventeenth day of illness

Etiology

It is proposed shortly to consider the various hypotheses that have been advanced on the etiology of war nephritis and to discuss the validity of each

Damp, cold, and exposure have been suggested by many writers as predisposing causes or even as the immediate causative agents of nephritis Hirsch at the Austro-German Medical Congress at Warsaw,[3] Pick,[4] and others lay special stress on this exposure theory During the Franco Prussian War, in which a German authority states that there was much nephritis, it is interesting to note that the chief fighting took place in wet weather But against this we have the incidence in the American Civil War, 1861-63, when the cases were most frequent in the summer months Again, Rose Bradford[5] notes that cases were few in the British Expeditionary Force until March and April, 1915, and that their incidence in the summer of that year was especially high Taken together, all these conflicting observations do not favour the supposition that damp, cold, and exposure are essential epidemiological factors

Forced marches have been suggested as a possible cause by Th Rumpel.[6] Certainly prolonged fatigue may produce albuminuria, but this is only transitory, and there is no evidence that this passing albuminuria predisposes to disease at a later date As a predisposition to renal disease it is as unlikely a factor as a surfeit of green apples is a factor in the cause of mucous colitis Typical war nephritis occurs among people who have been subject to no excessive muscular fatigue—e g, hospital nurses and orderlies and patients convalescing from some other disease and from injury

Streptococcal tonsillitis was suggested by Citron[7] as a cause We find no incidence of this, nor does Abercrombie in his paper[8] give any support to this hypothesis A few of our cases, but a few only, had a streptococcal infection—viz, impetigo, but the majority did not show this

Singer[9] considers that dysentery is a predisposing factor, and also that protective inoculation against enteric fever may lead to a stirring up of other organisms which had hitherto been quiescent No other writer has, as far as we can learn, considered dysentery to be a factor in the epidemiology of war nephritis, nor do our own cases lend any support to this view Again, there is nothing in the suggestion that inoculation or vaccination predisposes a man to nephritis Troops at home are not affected with nephritis, although they are vaccinated and inoculated against enteric

Lead, arsenic, and zinc have been accused of being the causative agents of this condition They can be ruled out at once The cases do not develop any of the well known symptoms caused by these poisons, and Mackenzie Wallis[10] has been able to show by ultra filtration that the urines of cases of war nephritis do not contain salts of the heavy metals

Thornley claims[11] to have isolated a small Gram negative diplococcus from the blood of cases of war nephritis As far as we can discover, this work has not been confirmed and our own blood cultures showed no such micro-organisms Mackenzie Wallis[10] considers that there are powerfully toxic agents in the urines of cases, and that the organism may be ultra microscopic He has not succeeded in producing the typical disease in animals

That the affection originates in the lung tissue has been suggested by Dunn,[12] who described changes in the lungs similar to those seen in cases of irritant gas poisoning It is possible that the pathological changes noted by this observer were the result of the purulent bronchitis, so often a complication, to which attention has been drawn already It seems rather to be an intercurrent affection than to have any causative influence on this disease Exposure to irritant gas could be absolutely excluded in the majority of our own cases

McLeod and Ameuille[13] conclude that the disease is due to deficiency of certain elements in diet and to the consumption of excessive protein They think that this is the most likely explanation of transient albuminuria, and that it may contribute towards the development of the more severe cases They are supported by Gaud and Mauriac[14] who consider that fatigue and deficient food elements are the most important factors in the causation of war nephritis

In the face of so many conflicting facts and theories regarding the epidemiology of this disease it may safely be said that the cause is still unknown

The possible infective nature of nephritis is suggested by the following points there is frequently a febrile onset, the disease according to Abercrombie relapses in about 2 per cent of cases which is one of the characteristics of protozoal infections, the slightly raised eosinophile count and the marked increase in large mononuclears support this hypothesis

Rose Bradford[15] and also Pick[4] have drawn attention to the comparative immunity of officers to war nephritis, and the former has also reported the complete immunity of the Indian troops to this disease The Indian troops suffered from all other war diseases, including bronchitis, but not from nephritis These facts suggest that British officers and Indian troops share something in common, or avoid something equally, which influences the onset of war nephritis In the British Army officers and men at the front line live under almost similar conditions all drink from the same water supplies, all breathe the same polluted air and live under the same unpleasant conditions The officers do, however, eat fresh food Even in the trenches during the Somme battle salads and fruit were seen in officers' dug outs When out at rest officers buy fresh food and vegetables and are able often to obtain new milk, in other words, they supplement their rations This applies equally well to officers living on the lines of communication or at the base, probably they have a "ration mess," but certainly they supplement their rations with fresh food The soldier, however, does not do this He draws his rations, but has little or no opportunity, even if he desires to do so, of purchasing fresh eatables The Indian troops were accustomed to eat fresh meat newly killed and not the frozen or canned meat of European troops They had fresh milk and not the tinned variety So, in common with British officers, the native troops obtained fresh food

It is perhaps a suggestive fact that in the urines of cases of beri beri Hewlett and De Korté[10] found a body similar in appearance to the endothelial cell We, too, have found endothelial cells in the urines of cases of beri beri imported into France with Asiatic labour

The hæmaturia of war nephritis, which is often persistent, is reminiscent of that which occurs in mild cases of scurvy It is interesting to note that the majority of cases had been in this country, and restricted living rations, for about seven months Experience of work with front-line battalions has impressed upon both of us the frequency of boils and skin eruptions, the scorbutic origin of which is suggested by their great improvement when a lime juice ration was instituted The objection may possibly be raised that the maximum incidence of the disease corresponds with the summer weather and the fruit season, this is met by the fact that fresh fruit and vegetables in France are beyond the financial resources or cooking abilities of the average soldier

Careful consideration of all the views discussed above leads us to think that war nephritis may be attributed to some error in metabolism due to dietary deficiency Our own observations would suggest the possibility of this, although we feel that our hypothesis is as yet by no means proved

We wish to express our thanks to Major A B Smallman, D S O R A M C, for his kindness in affording us access to the publications of other writers upon this subject

WOMEN AND THE INDIAN MEDICAL SERVICE —The Government of India is said to be considering the advisability of employing a certain number of medical women in the Indian hospitals with a view to setting free more medical officers for military service The names of medical women prepared to offer their services are being called for

MEDICAL DISPENSARY AND WORKHOUSE SALARIES IN IRELAND —The Lurgan board of guardians have (Sept 6th) adopted a graded scale of salaries for the medical officers of that union The new scale means that the salary of Dr W W Duff (Aghalee) will be increased from £100 to £145, Dr S Agnew's (Lurgan), £123 to £160, Dr H Reid's (Montiaghs), £110 to £135, Mr T H Brownrigg's (Moira), £105 to £150, Mr J L Rowlett's (Portadown), £110 to £160, Dr G Dougan's (Tartaraghan), £100 to £150, Dr W Frier's (Waringstown), £100 to £150, Dr J S Darling's (Workhouse), £130 to £155

A REPORT ON THE
TREATMENT OF *ENTAMŒBA HISTOLYTICA* "CARRIERS" WITH EMETINE BISMUTH IODIDE,
GIVING A COMPARISON BETWEEN THE KERATIN COATED TABLOIDS AND SALOL COATED PILLS

BY D G LILLIE, M A CAMB,
LATE BIOLOGIST TO THE BRITISH ANTARCTIC EXPEDITION 1910
AND
S SHEPHEARD, M R C S, L R C P LOND,
CAPTAIN R.A.M.C (T)

(*A Report to the Medical Research Committee from the Mont Dore Military Hospital, Bournemouth*)

THE treatment of the 104 cases dealt with in this report was carried out in a special ward set apart for the purpose. The cases were under the care of one medical officer in order to keep the conditions of treatment as uniform as possible Both forms of the drug were given in doses of 3 grains per day for 12 consecutive days without any additional treatment The tabloids and pills were given entire as a full dose during breakfast We have considered a case to be cured when he has had at least six or seven negative tests over a period of not less than seven weeks from the termination of his course of treatment The last one or two tests were made at the Barton Convalescent Depôt The great majority of the cases, however, had many more tests some were examined almost daily and were under observation for nearly three months after the end of treatment

First Course of Treatment

The number of men treated with one course of the keratin coated tabloids supplied by Burroughs, Wellcome and Co was 79 and the number of men who were given one course of the salol coated pills prepared by Allen and Hanburys was 25

We have found it advisable to divide these two sets of men into those who had injections of emetine hydrochloride before entering hospital and those who did not receive this treatment The results are as follows —

Cases without emetine injections —Forty five men were given one course of the keratin-coated tabloids and 29 were cured—i e, 64 5 per cent

Seventeen men were given one course of the salol-coated pills and 12 men were cured—i e, 70 per cent.

Cases with emetine injections —Thirty four men were given one course of the keratin-coated tabloids and 12 were cured—i e, 35 per cent

Eight men were given one course of the salol-coated pills and five were cured—i e, 62 per cent

Second course of treatment —Twenty four men who had relapsed after one course of the keratin-coated tabloids were given a second course of the same form of the drug and four were cured—i e, 16 6 per cent

Fourteen men who had relapsed after two or three courses of the keratin coated tabloids were treated with one course of the salol coated pills and four were cured—i e, 28 5 per cent

Effect of the Time Interval between the Onset of Disease and Treatment

The object of this part of the inquiry was to ascertain whether those cases which relapsed after treatment could be shown to be "carriers" of longer standing, in whom *E histolytica* had become better established and consequently harder to cure In order to make certain, as far as possible, that the onset of disease referred to was that of amœbic dysentery, only those patients were included under this section whose blood failed to agglutinate *B dysenteriæ* Shiga and *B dysenteriæ* Flexner

Cases without emetine injections —Out of 19 men who were cured by emetine bismuth iodide (E.B I) 7 (36 8 per cent) had an interval of over 20 weeks between the date of onset of their dysentery symptoms and the date on which they received E B I treatment The average interval for the 19 cases was 19 weeks

Out of 14 men who relapsed after treatment with E B.I 8 (50 7 per cent) had an interval of over 20 weeks between the dates of onset and treatment The average interval for the 14 cases was 22 weeks

Cases with emetine injections—Out of 12 men who were cured by E.B.I. treatment 10 (80·3 per cent) had an interval of over 20 weeks between dates of onset and treatment The average interval for the 12 cases was 29 weeks

Out of 14 men who relapsed after treatment with E.B.I. 11 (78·5 per cent) had an interval of over 20 weeks between the dates of onset and treatment The average interval of the 14 cases was 42 weeks

Influence of Other Factors

Vomiting—Out of 46 cases cured by the keratin-coated tabloids 40 vomited during treatment—i e 87 per cent The total number of days on which the 40 vomited was 288 The average number of vomiting days for those men who vomited gives a convenient coefficient for purposes of comparison—i e , 7

Out of 21 cases cured by the salol pills 14 vomited during treatment—i e , 66 per cent The 14 who vomited had 53 vomiting days—i e , vomiting coefficient 3 7

Out of 45 cases who relapsed after the keratin-coated tabloids 37 vomited during treatment—i e 82 per cent The 37 who vomited had 333 vomiting days—i e , vomiting coefficient 9

Out of 18 cases who relapsed after the salol coated pills 14 vomited during treatment—i e , 78 per cent The 14 who vomited had 63 vomiting days—i e , vomiting coefficient 4 5

Loss of weight—Out of 46 men cured by keratin-coated tabloids 24 lost weight—i e , 52 per cent

Out of 21 men cured by salol-coated pills 7 lost weight—i e , 33 per cent.

Out of 45 men who relapsed after keratin-coated tabloids 18 lost weight—i.e , 40 per cent

Out of 10 cases who relapsed after salol-coated pills 5 lost weight—i e , 50 per cent

Effect of age on curative results—The average age of 38 cases cured by keratin-coated tabloids was 27 6 years 11 men out of the 38 were over 30 years of age

The average age of 38 cases which relapsed after keratin coated tabloids was 28·9 years 11 men out of the 38 were over 30 years of age

The average age of 17 cases cured by salol-coated pills was 28 7 years 4 of the 17 were over 30 years of age

The average age of 17 cases which relapsed after salol coated pills was 28 4 5 of the 17 were over 30 years of age

Effect of age on vomiting—36 men under 25 years treated with keratin-coated tabloids had 271 vomiting days—i e , vomiting coefficient 7 5

26 men over 30 years treated with the same tabloids had 157 vomiting days—i e , vomiting coefficient 6

7 men over 40 years treated with the same tabloids had 22 vomiting days—i e , vomiting coefficient 3 1

Conclusions

The conclusions which we think may be drawn from the foregoing facts are as follows —

1 (*a*) That "carriers' of *E histolytica* who had not had any injections of emetine hydrochloride were cured to the extent of 78 per cent by two courses of the salol-coated emetine bismuth iodide pills (*b*) In the case of men who had had emetine injections 72 8 per cent. were cured by two courses of the salol coated pills (*c*) In the case of men who had not had emetine injections 70 per cent were cured by two courses of the keratin coated tabloids (*d*) In the case of men who had had emetine injections 45·4 per cent were cured by two courses of the keratin coated tabloids

The difference between the percentages in (*a*) and (*b*) are within the range of experimental error and need not be considered But in (*c*) and (*d*) the difference is too great to be ignored This difference may be due to variation in the quality of the keratin-coated tabloids, but such a defect would be common to both cases which had received injections of emetine and those which had not. It is generally admitted that certain carriers of *E histolytica* are not cured by emetine in any form and it may be, as Mr Dobell suggests that these cases become segregated in (*d*) It seems possible that the difference in the two percentages may be due to the injections of emetine rendering the carriers ' less liable to be cured by E.B I

For comparison with the above percentages of cures by a maximum of 72 grains of E B I carried out in the special ward we give the number and percentage of cures in the other wards of this hospital The number of grains of E.B I which these cases received varied from 38 to 200 A case was regarded as cured after not less than 5 negative examinations over a period of not less than 5 weeks after the end of treatment The last test was made at the Barton Convalescent Depot. Out of 160 cases treated 142 were cured—i.e 88 7 per cent.

2. There is no evidence that the length of time between the dates of onset of dysentery symptoms and the treatment has any effect upon the chances of cure by E.B I

3 There is no ground for the belief that the vomiting diminishes the chance of cure by the E B I treatment There is nearly as much vomiting among the cases which are cured as among those which relapse.

4 The age of the patient has no effect upon the chance of cure by the drug But there is evidence to show that men over 40 years of age vomit less while undergoing treatment

5 The salol coated pills are a distinct improvement upon the keratin coated tabloids from a curative point of view They also cause less vomiting and loss of weight

In conclusion, we express our hearty thanks to Temporary Honorary Captain A C Inman, R.A.M C , Mr W O Redman King and Mr A G Thacker for making some of the examinations for us and for help in many ways To Lieutenant-Colonel T H F Clarkson R A.M C , officer commanding, Mont Dore Military Hospital, Bournemouth, we are indebted for permission to publish this report

THE TREATMENT OF FUNCTIONAL CONTRACTURE BY FATIGUE

BY E F REEVE, M B , B S LOND , M R C S ,
L R C P LOND ,
CAPTAIN (TEMPORARY) R.A.M.C MILITARY HOSPITAL, MAGHULL.

ONE of the most striking and obstinate of the objective disabilities displayed in the functional war neuroses is muscular contracture The majority of the functional disorders met with are due to the absence or diminished activity of a normal function, and are easily and rapidly curable by suggestion and re-educative measures Contractures on the other hand form part of a group of cases dependent not so much upon the absence of a normal function as upon its excessive and disordered activity As a general rule, they are not very amenable to treatment by suggestion and re-education. —

The object of this paper is to describe a method which the writer has used in dealing with this type of war neurosis He has seen no reference to this treatment in the literature, and, as far as he knows, it has not been used by others The advantage of the method is that once a diagnosis of functional contracture has been made no special experience is required in the carrying out of the treatment

In the cases which have come under my care this treatment has invariably proved successful in the course of a few days although most of them had been treated without benefit for long periods in various hospitals by other methods The principle of the treatment simply consists in *producing a condition of fatigue in the muscles responsible for the contracture* This is obtained by continuous passive movements in a direction opposed to the normal action of the contracted muscles A good deal of force is often necessary in the early stages of the treatment but as time goes on the spasmodic return of the muscles becomes slower and weaker until finally a limp, toneless, and fatigued condition is brought about The offending muscles are then no longer able to produce the deformity for which they were responsible

In the case of the more powerful muscles it may be necessary to continue the forcible movements for many hours before the condition of fatigue results, and relays of men must be 'told off ' to relieve each other, so that the muscles may get no opportunity of recovering their tone. In my own wards I have been in the habit of getting patients to assist in the work and in particular I find it helpful to make use of those who have themselves been cured by the same kind of treatment

It is always my custom carefully to explain matters in the simplest language to the patient before commencing the treatment I describe to him the nature of a spasm and tell him that once it is relieved he will be able to bring into action opposing muscles which are now unable to perform their functions on account of this persistent spasmodic contraction

Illustrative Cases

It will be seen from the description of the cases given below that many of them have been suffering from these contractures for a great length of time Almost every case has been treated by one or all of the following methods fixation in splints electricity, passive movements, and suggestion with or without hypnosis In some cases the fixation had been effected under general anæsthesia

Case 1 —J D aged 28 Had been fighting in France from August 18th, 1914 and had twice previously been wounded On July 14th, 1916 he was wounded a third time, a machine-gun bullet going through the fleshy part of the left forearm The hand immediately became clenched and continued so after the wound had healed and the dressings had been removed The fingers could be forcibly opened but became clenched again immediately they were released He was treated by electricity massage, passive movements and fixation for weeks together in a straight splint, but up to the time of his admission to Maghull Military Hospital on April 18th 1917, no improvement had resulted

Two days after admission treatment was begun The condition was thoroughly explained to the patient and he was told that after fatiguing the flexor muscles to such an extent that they would no longer be able to pull the fingers into the clenched position the antagonistic muscles on the back of the forearm would be able to perform their work. The second stage of the treatment then followed For six hours without interruption the fingers were forcibly opened and opened again directly they closed into the palm of the hand After a few hours the fingers returned more and more slowly, till at last they remained straight out in the extended position

The following morning the fingers were still straight out and the condition of spasm has never returned At first the extensor muscles were very feeble in their action but improved daily When discharged from hospital on July 2nd 1917, the patient s hand was as strong and useful as it ever had been

Case 2.—J D , aged 20 was wounded by a rifle bullet on July 10th 1916 the bullet going through the fleshy part of the back of the neck. The wound healed satisfactorily and the patient was discharged from hospital on Oct 1st 1916. Two weeks after returning to his depôt there was a Zeppelin raid and the troops were turned out in the middle of the night In the morning his neck was found to be twisted round and bent over on to his left shoulder After treatment in various hospitals for several months, fixation in the corrected position by plaster of Paris was resorted to but the deformity returned immediately the bandages were removed.

The patient was admitted to Maghull on April 18th, 1917 There was strong spasm of the left trapezius and right sterno-mastoid muscles causing the neck to be drawn down on the left shoulder and rotated The deformity was easily corrected under hypnosis but the condition returned A week after admission the neck was forcibly straightened and straightened again as fast as it returned to its old position After some hours, the offending muscles were in a condition of fatigue, and the neck remained straight The following morning a slight return of the deformity was noticed, and the procedure of the previous day was repeated From that day the neck remained straight and the condition did not return The patient was discharged from hospital on July 2nd

Case 3 —F C aged 27 was wounded in left forefinger on July 18th 1916 by machine-gun bullet Again wounded on Feb 18th 1917 on back of right knee by piece of metal, and remained for 36 hours in a shell hole before being picked up A few weeks later he noticed that he was unable to use the left hand and a note on the medical history sheet, dated March 24th states that the hand was in a position of ' main en griffe " He was admitted to Maghull Hospital on June 6th 1917 Two days after admission the fingers were forcibly straightened as in Case 1 After some hours the deformity failed to return, and from that time onwards the hand has not come back to its abnormal position

Case 4 —C M aged 32, was buried by a shell on August 2nd, 1916 He was not wounded but was extensively bruised about the back He remained constantly in bed till February 1917 Up to that time any attempt to move his legs brought on severe tremors He was then allowed up and efforts were made to get him to walk However any attempt at walking involved kicking one foot with the other As a result of this his ankles became so bruised that it was necessary to pad his feet with cotton wool

On admission to Maghull on June 12th 1917 it was noticed that one leg was crossed over the other and that the adductor muscles of the thigh were in a state of spasmodic contraction More especially was this the case on the right side The thighs could not be separated without using a good deal of force Obviously this spasm had to be reduced before walking could be attempted

The patient was laid on his back and the thighs were forcibly separated, each leg being pulled by a man The separation was repeated as quickly as the thighs met again Three days' hard work of four hours a day were necessary before the spasm was fully reduced. On the fourth day the patient was able to walk with assistance On the sixth day he walked a distance of over a mile without help and the spasm has never returned

Case 5 —W H aged 37 was knocked over by a bursting shell in September 1916 For some months he was unable to walk or even to stand, there were general tremors and his left foot was fixed in a position of marked flexion On admission to Maghull on Dec. 20th 1916 he could not walk without assistance the sole of the left foot was drawn up by spasmodic contraction of the flexor muscles of the front of the leg, and his weight when treading on the left foot was borne entirely on the heel He was treated by repeatedly extending the foot against the resistance of the contracted muscles After some hours the spasm of the flexor muscles disappeared and the foot could be moved without resistance as desired He quickly walked quite naturally and was discharged on May 11th 1917

Case 6 —E M , aged 29 was wounded by a rifle bullet on June 4th 1915 The bullet entered through the intraspinous fossa of the right scapula and passed out through the pectoralis major just internal to the head of the humerus The patient stated that an operation was performed for joining the nerves two months later and that the wound became septic, necessitating further operations for the purpose of drainage Note in medical history sheet states: 'Since August, 1915 the arm has been fixed to the side and every attempt to move it evokes strong muscular spasm The elbow is extended by contraction of the triceps For a long time the fingers were tightly flexed and the wrist extended, but this condition cleared up in March 1917 only to recur in May " A further note dated June 8th 1917 states ' Electrical massage gives free movement, but spasm returns in half an hour

The patient was admitted to Maghull on June 12th 1917 The arm was tightly held to the side. It could be forcibly abducted but sprang back like the blade of a clasp knife, on being released The arm was held rigid by the triceps muscle and the elbow could not be voluntarily flexed there was however, free movement of the wrist and fingers

Treatment was begun three days after admission At first the elbow was forcibly flexed and this operation was repeated for some hours until at last all trace of spasm had disappeared The following day, the forearm being still freely moveable at the elbow the arm was forcibly abducted and this movement was repeated again and again until after some four or five hours the limb could be held voluntarily away from the body A good deal of force had to be used at first so much so that it was necessary for one man to steady to body while another forced the arm away from the side This forcible abduction of the limb from the body was repeated day after day till at the end of the week the patient was able to lift his hand to the back of his head, all trace of spasm having disappeared.

Case 7 —T W , aged 24, was buried by a shell in February 1915. He was unable to walk had general tremors, and was kept in bed for about four months. On getting up it was noticed that his feet were strongly inverted so that on standing all his weight rested on their outer edges An attempt was made to correct the deformity by means of splints but the condition was quite unimproved at the end of three months Strong faradic currents, massage and passive movements were then tried but with equal lack of success Finally he was fitted with special boots designed to tilt the foot over into the correct position by means of leather wedges The condition, however still remained unimproved

The patient was admitted to Maghull on Nov 18th, 1916. On admission the feet were strongly inverted and a good deal of force was necessary to straighten them He walked on the outer edges of his feet with the help of two sticks He was treated by exercises, passive movements and suggestive and re-educative measures. He improved up to a certain point and after some months he could get about without the help of sticks The condition of claw foot," however, still persisted, although not to the same marked extent as on admission

Treatment by fatigue was commenced at the end of June For eight hours without intermission the feet were forcibly flexed and everted At the end of this time the deformity had entirely disappeared but returned to a slight degree the next day Another sitting of eight hours effected a complete disappearance of the spasm, and the contraction has not returned He now walks on the flat of his feet and his gait is perfectly normal He was discharged on July 20th 1917

Case 8 —A. W aged 27, was wounded on Oct 22nd, 1916 by a shrapnel bullet which went through the fleshy part of the back of the left forearm The hand immediately became clenched and remained so although the wound healed satisfactorily For four months the fingers were kept straight by means of splints, but every time they were taken off the contracture returned.

On July 5th 1917 he was sent to Maghull. The fingers were tightly clenched and had obviously not been opened for many weeks for when forcibly straightened the skin on the palmar surface of the hand and fingers was found to be in a sodden condition and emitted a most offensive odour A good deal of force had to be used to get the fingers open partly owing to fibrous adhesions along the course of the flexor tendons, and they contracted into the hand again directly they were released Repeated forcible extension was persevered with for many hours for two consecutive days At the end of this time the fingers remained out limp in the extended position and the contracture has not returned

Some General Considerations

This form of treatment follows the lines of the general methods employed at Maghull The nature of the disability is explained to the patient and he is made to understand the curative measures as they are carried out. That this is a distinct advantage there can be no question, for not only can the patient in many cases coöperate in his own cure, but he in his turn helps later on in the treatment of others Thus a curative atmosphere is developed in the ward the value of which it is impossible to overestimate (See *Note* at end)

Further advantages of the treatment are —

1 No apparatus of any kind is required and no specialised knowledge on the part of the physician is necessary

2 It is accessible to all, since the personal influence of the physician does not operate to the same extent as in treatment by purely suggestive methods That such personal influence must come into play to some degree cannot be denied, for although the patient's cure is brought about in the first instance by a purely physical means, psychical factors must operate once fatigue has worn off It is probable, however, that the all important factor which conduces to the permanency of the cure is the actual demonstration to the patient that the contracture no longer exists, it having been dispersed by a method which he has no difficulty in understanding

3 It is applicable to cases which have been treated previously without success by other methods, and its success is not prejudiced by these previous failures It therefore appears to be preferable to suggestive measures

4 The process by which the contracture is actually eliminated is a physiological one and is not subject to interference from psychical factors—e.g , the degree of the patient's faith that he will be cured

5 Any fear of a relapse is distinctly reduced by the patient's knowledge both of the mechanism by which the disability was produced and of that by which he was cured

6 Such a method does not undermine the patient's self-respect in the slightest degree , in fact, in most cases it may increase it by deepening his self knowledge and convincing him that his disability is a natural phenomenon and not something occult

Cases 6 and 7 are of special interest in that they had both been in hospital for more than two years before treatment by fatigue was resorted to In each case the disability was cured in less than a week.

I am told that the condition called "claw foot" is the most common of the contractures met with in this war, and that it is particularly intractable. Many are sent out of hospital fitted with an 'inside splint," and remain for months or even years with little or no improvement It seems highly probable that such cases could be cured in a few days by the method above described

The idea suggests itself too, that this method might be applicable to those contractures met with in civil practice in the grave forms of hysteria.

Objective and Subjective Symptoms

As this paper deals only with the treatment of muscular contracture, no mention has been made of any accompanying subjective symptoms Such troubles, however, were present in more or less marked degree in all the cases It is very doubtful if a hard and fast line can be drawn between "subjective" and 'objective' symptoms

From the physician's standpoint it may be easy but to the patient it may matter little whether his trouble expresses itself to others through a physical symptom or is known only to himself In fact, the distress caused by the "subjective" troubles is often greater than that due to the "objective" troubles Doubts, fears, hesitations, obsessive thoughts of all kinds often oppress the patient who *seems* to be suffering merely from muscular contraction To allay these is the physician's plain duty Indeed, the future may show that in the causation of these "objective" troubles psychical influences have played the major rôle, and until investigation has cast more light upon this fascinating problem we must not speak too hastily of purely 'objective" symptoms Attention should always be paid by the physician to the individual history of the case, and especially to the way in which the patient himself regards his trouble If this is done, not seldom will the patient leave hospital a wiser and stronger man in that he knows himself better

The fundamental principles underlying the form of treatment above described have not been discussed It is hoped, however, that the whole subject will be elaborated in greater detail in a subsequent communication In conclusion, I wish to express my thanks to Major R. G Rows officer in charge of the Military Hospital, Maghull, for permission to publish these notes

Note —It may be pointed out that this curative atmosphere is of the greatest help to the physician in his treatment of the purely subjective troubles met with in the psycho-neuroses It is sometimes forgotten that "psychical infection" which is so much feared by those who deprecate the treatment of neurasthenics in special hospitals often has a beneficial effect in that patients who are getting better are able to convince others suffering from similar troubles that their own cure will come about in due course

ACTIVE TREATMENT IN ESTABLISHED ECLAMPSIA

BY GILBERT I STRACHAN, M D GLASG ,
M R.C P LOND ,

LATE RESIDENT OBSTETRICIAN THE ROYAL GLASGOW MATERNITY AND WOMEN'S HOSPITAL LATE RESIDENT GYNÆCOLOGIST THE WESTERN INFIRMARY, GLASGOW

IN this paper I propose to confine myself to the active treatment of the fully-established condition

Methods of treatment had best be considered under two headings, palliative and radical or operative, and naturally we have a much wider range of choice in the former than in the latter class As a palliative measure sedatives are urgently indicated , this point is agreed on by all Morphia is probably the best, and is certainly one of the best of these, but it must be properly used , Bumm and Jardine, however, are averse to its use I have found the following a safe and efficient method of administration as soon as possible after the case comes under observation give gr ½ as an initial dose, if necessary give another gr ¼ in two hours' time, and if necessary repeat the smaller dose in another two hours but give no more than the three doses Mostly a satisfactory sedative result is obtained , if not, more radical measures will be necessary If used carefully as described I have never seen any harmful results accrue from its administration, nor have I ever seen any evidence of its supposed damaging effect on renal tissue Chloroform is most valuable as a sedative although such authorities as Tweedy and Ward are strongly opposed to its administration They hold the drug responsible for harmful hepatic lesions, and liken its administration to that of an antipyretic in a case of fever It is best as an adjuvant to operative treatment , if administered in big doses and over a long period it is certainly deleterious, and then may cause liver lesions very similar to those found in established eclampsia Therefore in giving it give as little as possible to produce the sedative effect aimed at Chloral hydrate with potass bromide are of more use for general restlessness between fits than for actual convulsions I have never seen any real sedative effect from these drugs alone in eclampsia Paraldehyde, on the other hand, I have always found sound and absolutely safe Two drachms rectally, with repetition of half that dose if necessary at two-hourly intervals, is usually as efficient as the largest dose of morphia and is without any of the contra indications of that drug I am strongly of opinion that paraldehyde has not yet reached its proper place in professional estimation

Great attention is to be paid to the general surroundings of the patient make only one and that one a complete pelvic examination then leave the patient in peace, lest by unnecessary pelvic stimulation fresh fits be set up

In general terms, then, exclude everything acting unduly on the visual, aural, tactile, or other receptor systems and the attaining of these desiderata will include good nursing, a suitably warmed and darkened room, and experienced attention Stroganoff, of Petrograd, has of late perfected sedative treatment, space forbids a full account of his methods but by paying attention to all these factors and details in recent years he has managed to reduce his death-rate to 6 per cent , which is quite a wonderful figure, and other obstetricians who have followed the details of his treatment also quote much improved results Some writers recommend circulatory sedatives and vaso-dilators, as hæmorrhages in various organs are of such frequent occurrence in this disease, but I have never used them, as they can have no important place in treatment Zinke uses veratrum viride and speaks well of it, while hydrate of amyl is used by Hürle and others with improved quoted results, but my personal opinion is as stated.

Elimination must play a large part in any system of efficient treatment the stomach and bowel must first be thoroughly washed out and then a hydragogue purgative administered In this respect mag sulph , grs 60 daily or pulv jalap co , grs 90 as required, will be found the most efficient , croton oil I have found disappointing and of little purgative value in these cases, while Jardine has reported a case where œdema glottidis followed its exhibition By these means the alimentary tract—a possible source of toxin manufacture—can usually be satisfactorily cleared out Diaphoresis usually gives excellent results, but the pulse must be watched, although I have never seen any collapse during this The hot pack or hot-air bath are the most useful agents in the matter,

Now the toxic substances are circulating in the blood, and by withdrawing a certain amount of blood a certain amount of toxin will be abstracted, while if fluid be introduced to replace the abstracted blood the remaining toxin will be diluted and at the same time the kidneys stimulated to more active excretion These conclusions have been substantiated in practice and in a case of normal severity 15 to 20 fl. oz of blood may safely be withdrawn from a median basilic vein, while at the same operation 2 to 3 pints of normal saline may be introduced into the vein

Jardine and others at first used sod acet on account of its supposed diuretic action, but they quickly found that normal saline was just as effective Generalised œdema is usually held as a contra indication to transfusion, but I have not found it so , however, œdema of the lungs certainly is, and with such a condition present saline should certainly be withheld lest the œdema be accentuated and the patient literally drowned If the case be less urgent the rectum will be found a most useful channel of administration I have no doubt as to the efficacy of this line of treatment, and I have seen rapid and great improvement in almost every case in which it was tried, and certainly in every case of moderate severity These are the main lines of sedative treatment as at present practised, and we can now consider the more radical or operative methods and the indications for their application

Before discussing the commonly employed forms of operative treatment, I shall remark on certain procedures which have never become popular mostly for reasons which will be obvious Renal decapsulation, the first of these, was introduced by Edebohls, and has at times been practised and recommended by various American and European obstetricians of repute It aims at relieving renal congestion but as this is only an accompaniment and certainly not a cause of eclampsia its basis is obviously unsound. It is typically an operation which is likely to do far more harm than good I have never seen it performed, and never intend to perform it personally

Sellheim s operation of amputation of the breasts (the supposed place of origin of the causative toxic substance) must rely on the accompanying loss of blood for any good that may ensue It is a farcical procedure, and is not seriously regarded at the present day To empty the uterus, however, is the keystone of our operative efforts, and is a most rational procedure A safe rule in practice is this unless a case of eclampsia be showing immediate, speedy, and considerable improvement by palliative treatment, empty the uterus at once Consider only the mother's interests, and entirely disregard those of the fœtus Bumm quoted 30 per cent mortality with expectant treatment, but since 1901 he has delivered as soon as possible after the first fit, and now reports a mortality of 2 per cent —truly a changed figure Most obstetricians will agree with me in recommending this line of treatment, although Ballantyne and Stroganoff, amongst others, still advocate expectancy In most cases labour will have set in, and if so, the uterus may be left to empty itself, possibly with the help of forceps, but unless some strong indication be present—e g , extreme collapse—no rough method of haste must be employed However, if dilatation be too slow, and the eclamptic condition becoming worse, operative cervical dilatation is called for

Forcible dilatation by hand or by Harris's dilators must be done if at all only with very great care, as so much operative shock is caused by such a procedure In such a case I strongly recommend incising the cervix , the accompanying loss of blood is of benefit and full dilatation is immediately secured Again, any necessary intra uterine manipulation may now be proceeded with , of these latter version and forceps will be the most often called for, and version will be indicated, especially when speed is required—e g , when a fœtal heart be heard

When the uterus is emptied as described, and unless the case be very grave and far advanced, immediate and continuous improvement will be noticed and recovery will be rapid, contrasting strongly with the uncertain and anxious state of affairs when purely expectant treatment is relied on Cæsarean section has been employed in only a few cases to empty the uterus, and the cases are too few and the results too uncertain yet to speak definitely of it. The maternal mortality is roughly about 50 per cent in published cases, so that *prima facie* the operation does not recommend itself Unless for mechanical reasons—e.g , contracted pelvis—I can see no prospect in performing the operation for eclampsia

These, then, are my conclusions regarding the active treatment of eclampsia , I present them in no dictatorial spirit, but merely as the result of recent clinical observation and study

Cardiff

TWO CASES OF GUNSHOT FRACTURES OF THE MANDIBLE WITH LOSS OF SUBSTANCE

BY RICHARD J GREEN, L D S ENG

THE necessity for efficient treatment of fractured jaws grows more urgent every day Deformity of the face means, in many cases, unhappiness, but is, together with an impaired masticating action, nearly always avoidable. The treatment is, in most cases, better left to the dental surgeon, who, by his training, is particularly adapted to make use of mechanical appliances to achieve the best result, and knows the great importance of correct articulation

I wish to emphasise this most strongly, because during hospital practice and work with the South African Field Forces I have so often seen bad results due to lack of special training on the part of the general surgeon

Too often in busy hospitals the old four tailed bandage is made to serve, and wiring of the jaws, so much practised by the general surgeon, often ends in the "open bite," or leaves the mandible considerably deflected to one side or the other, altering the appearance of the patient. It is in war time particularly that the dental surgeon should be encouraged by having many hospitals for gunshot fractures of the jaws only This field of surgery is a small one and the manipulative skill of the dental surgeon is high

CASE 1 —Private ——, aged 18 *History* The patient was hit by a machine gun bullet at the close range of nine yards on April 18th, 1915 The bullet passed through the mandible immediately behind the mental foramen on the right side, carrying away a large piece of bone and causing much splintering It struck his teeth with force, and in its deflected course carried away the crowns of all his teeth (with the exception of the right upper and lower wisdom) the anterior third of his tongue, his superior maxillary bone on the left side, and the corner of his mouth, together with a piece of cheek He lay partly unconscious for nine hours, was taken to a base hospital, and a four tailed bandage was applied He was sent to England 12 days afterwards, on April 30th On admission the condition of his mouth was very bad He had a swollen tongue and lips, an extremely sensitive upper jaw, and the exposed pulps of many teeth all bathed in a pool of pus He was nervous but otherwise in fair condition

First operation (six weeks after admission, June 11th) —(It will be seen that no form of wire splint attached to teeth was possible he had no teeth, and no splint in the form of a Gunning could be used, because half his superior maxilla had been shot away and was extremely sensitive) I decided to plate the lower jaw with silver No 8 plate and fasten it in position with three silver plated brass screws The plate was 1¼ in in length, shaped rather like a cradle, but open at the ends, ¼ in high on the buccal surface but only 1/16 in on the lingual (Fig A) The screws were ¼ in long and of a very small gauge During the operation I removed some large sequestra and fibrous attachments The mandible was considerably deflected downwards and to the right side I applied a little pressure and forced the jaw into correct position By means of a cable attachment to a small electric motor, and using spear and rose head burs, I drilled the necessary screw holes into the jaw bone avoiding the inferior dental canal, and fastened the plate in position, which firmly held the fractured ends He was a lively patient, so the sister in charge suggested a further protection in the form of a chin and jaw frame of perforated wire gauze, edged with rubber strapping

FIG A

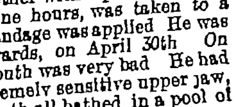

Plate seen from the lingual side.

Second operation (August 25th, 1915) —I removed the plate and his "middle line" had been preserved, which is my chief reason for reporting this case, as I do not think by any other method it could have been successful I extracted all the roots of his teeth one week afterwards, and freed the upper lips of its cicatricial attachment to the alveolus, thus making a false sulcus

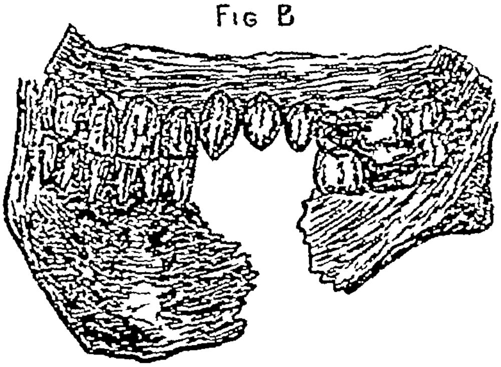
In December, 1915, he complained of pain in his left maxilla I found he had suppuration of his left antrum of Highmore I opened it under novocaine, and packed with gauze dipped in tincture of iodine, B P strength This was left for 48 hours and then removed After syringing for seven days with glyco thymoline it was allowed to close and all discharge ceased Of 17 cases of suppuration of the antrum of Highmore this case cleared up soonest I believe this method should always be tried first before tubes or something more radical is attempted

Six months after the extractions the dentures were inserted but as the patient complained of a tingling sensation on the right side of the mandible I opened up the inferior dental canal under novocaine, injected cocaine into it, dragged the nerve outwards without causing pain, and cut off half an inch, the tingling sensation did not recur He was discharged in March, 1916

CASE 2 —Private ——, aged 19 (Wounded April 18th, 1915) *History* A bullet at a range of 150 yards struck the lower part of the thorax on the left side, passed upwards, apparently without injury to his lungs, and came out near the middle of his left clavicle It then struck his mandible (probably broadside on) in the region of his premolar teeth carrying away 1¼ in of bone, entered his mouth and passing over his lip without causing injury, was caught in his hand On admission (April 30th, 1915) there was a large sinus, a copious discharge of pus, no pain, and the jaw was very much deflected downwards and to the left side

Method of attaching appliance —Four "Angle bands" were attached to the patient's 12 year lower molars and 6-year old upper molars as in Fig B These bands are gold plated with nut and thread for tightening purposes and with a stud to which one can attach ligatures To the studs I attached a figure-of 8 wire ligature on each side of his jaws and using pressure held the jaws in proper position—the teeth intercuspidating—tightened the ligatures, and kept the jaws closed in this position for ten weeks The patient was fed with liquid diet through the space left by his left lower canine and premolars which had been carried away Many sequestra worked out the sinus healed, and strong bony union took place no shrinkage occurred after the removal of the bands, his teeth intercuspidated, and his middle line was correct

FIG B



Angle bands in position with stud screw and nut figure-of-8 wire ligatures attached similar bands on opposite side of jaws

Had I wired the jaws in this case I think it probable that the fine splintered pieces in contact would have been disturbed and fibrous union would have resulted

Bandaging wiring and fastening teeth together by means of ligatures tied to adjoining teeth are crude relics of the past the general surgeon has no facilities to avoid these methods

Sunderland

PROFESSORS IN INDIAN MEDICAL COLLEGES —The educational conference recently held at Bombay decided to urge the Indian Government to select professors for the Government medical colleges from the entire medical profession in England and India outside and inside the services A resolution was passed advocating the necessity of an adequate system of research scholarship to be started and maintained by the Government for the advancement of scientific knowledge

THE EFFECT OF X RAYS UPON DISEASES OF BACTERIAL ORIGIN[1]

BY CHRISTOPHER KEMPSTER, M R C S,
L R C P LOND,

PHYSICIAN IN CHARGE OF X RAY AND ELECTRO-THERAPEUTIC DEPARTMENTS OF ST JOHN'S HOSPITAL FOR DISEASES OF THE SKIN AND CITY OF LONDON MILITARY HOSPITAL ASSISTANT X RAY AND ELECTRO THERAPEUTIC DEPARTMENT CANCER HOSPITAL, LONDON

DURING recent years there has been an increasing application of the X rays as a means of treatment of diseases of bacterial origin both superficial and deep-seated, with results which have in many cases been surprisingly successful, cases which had under other methods of treatment either become worse or had not improved at all making a rapid recovery This has naturally led to an inquiry as to the reason of the improvement, and consequently as to whether the X rays possessed any specific germicidal action

Close observation and examination has led to some complexity of opinion upon this point, some observers being of the opinion that the X rays do not possess any such power, whereas others are equally of opinion that the germicidal action of the rays is undoubted It would be difficult to find opinions more diverse than these, but, nevertheless, the adherents to each of these conclusions have some good reason for their assumption Those who declare that the X rays are non germicidal bring evidence to show that germs which were present before irradiation are still there after that operation, and those who are of opinion that the rays possess a decided germicidal property give equally substantial evidence in support of their contention by producing cases which have become sterile of the infecting micro-organisms after treatment

Upon the principle that there is no result without a cause, there must be some good reason why evidence so contradictory can be produced for it is certain that investigation upon thoroughly scientific lines has led to the conflict of opinion, and it appears probable that the investigations have been made in different directions The one set of investigators have based their claims upon findings made as the result of experiments and observations of the action of X rays upon bacteria in *inert* or dead *media*, whereas the other set have based their claims upon the result of the action of the rays upon micro-organisms in *living animal tissues*—a distinction of the utmost importance and one which will reconcile these opposite opinions and prove them both to be true

It will therefore be interesting to inquire into the effect of X rays upon bacteria first in *inert media* and then in *living animal* tissues We shall then see that the action of X rays upon bacteria in inert media is not germicidal, and we shall also see that the absence of bacteria in living animal tissues after irradiation is not due to the lethal action of the X rays but to the stimulation of the living animal tissues leading to increased phagocytosis and so to the disappearance of the micro-organisms, but that the phagocytosis is materially aided by the action of the X rays upon the bacteria

Results of Experiments

To this end we will now inquire into a few experiments

If fresh plate cultures of tubercle bacilli be exposed to the X rays in such manner that one-half of the culture plate be protected from the action of the rays by means of a lead sheet, it will be found that upon the portion of the medium covered by the lead growth of the bacilli will have taken place, whereas upon the exposed half no such growth will be evident although the bacilli placed there will still be present Again if developed colonies of bacilli be exposed to the X rays they will not be destroyed by the exposures, but no further development will take place[2]

It is evident from these experiments that the micro-organisms are not destroyed by the rays, but that their growth is stopped, and it has been found impossible by any ordinary long exposure to high vacuum tubes to kill growths of bacilli by X rays[3]

Bergonié and Mangour demonstrated that they were unable to destroy the virulence of tubercle bacilli by exposing sputum containing them to the X rays, for after an exposure of six hours to the rays at a distance of 20 mm from the tube the tuberculous sputum when injected into guinea-pigs caused acute miliary tuberculosis in all the animals injected [4]

[1] A paper read before the London Dermatological Society

[2] Münch med Wochenschr., 1898, xlv 773 1902 xlix 402

[3] Compt rend Soc Biol 1897 (Série 10) iv, 609 Archives Röntgen Soc 1900 v 3

This subject has claimed the attention of many bacteriologists, and from the results of their work there is undeniable proof that the X rays themselves have no germicidal properties and that the germicidal influence of the X rays themselves upon the bacteria is practically nil. We have thus seen that the germicidal action of the X rays upon bacteria in inert cultures is practically negative, the effect of the rays upon micro organisms in living animal tissues, however, is quite different

Pusey and Caldwell [5] say that when a suppurating ulcer is exposed to the X rays unmistakeable evidence of interference with the growth of the pus organisms is shown The discharge changes from pus to a sero-purulent and then to a sero-fibrinous fluid, and soon the ulcer becomes clean and free of contamination with pus organisms This drying up and cleaning of infected ulcers has been noted by many observers, and it occurs regardless of the character of the ulcer, dirty septic ulcers of carcinoma, syphilis, and lupus become clean and sterile under the influence of X rays alone *without the use of antiseptics in localities where cleanliness* cannot be maintained, it is, therefore, clear from this cleaning process that the micro-organisms responsible for the septic conditions have been destroyed as a result of the exhibition of the rays to the living animal tissues

In order to demonstrate the effect of tubercle bacilli in living animal tissues, experiments were made upon eight guinea pigs, which were inoculated in the inguinal region with tubercle bacilli Three of them were then exposed to the X rays, and all three remained well, whereas the five guinea pigs which were not exposed to the rays all developed tuberculous diseases at the point of inoculation [6]

Pusey and Caldwell have emphasised the fact that organisms can be destroyed by exposures to X rays when situated in living animal tissues, whereas the same organisms in inert cultures are not destroyed by the X ray exposures, proving that it is not the influence of the X rays themselves that causes their destruction, but that the living tissues, doubtless under conditions of activity excited by the X rays, play an important part in this germicidal process, and that it may well *be imagined that this process is in the nature of* stimulation of the cells, which are rendered thereby better able to take care of themselves against the invasion of the organisms, and that this effect on bacteria is caused by increased phagocytosis

Conclusions

It might well be said that if the increased phagocytosis is due to increased stimulation of the tissues, what proof is there that the X rays play any part different from that of any other stimulant applied to the region? The answer is that if tuberculous glands, such as are commonly met with in the cervical region, be subjected to the influence of the X *rays, they will in course of time atrophy* and become sterile of tubercle bacilli whereas glands of a similar nature exposed to stimulation of other kinds, such as fomentations poultices, iodine, &c, do not atrophy and become sterile, but rather increase in size and bacillary virulence

We thus see that the phagocytosis encouraged by the applied *stimulation, is not alone sufficient to prevent* infection, it follows, therefore, that the X rays must play an important and specific part in the prevention of the infection by and in the destruction of the bacilli

We found that when the tubercle bacilli were exposed to the rays they did not form colonies, and we also found that developed colonies exposed to the *rays did not grow, that* the bacilli were not destroyed in either instance but that their increase and multiplication had been inhibited

This, then, is the reason why inoculated guinea pigs when subjected to the influence of the X rays do not develop tuberculous lesions The phagocytes are equal to the task of destroying the germs inoculated into the *animal if the germs* are deprived of their power of rapid reproduction but if their reproductivity is not inhibited the phagocytes are unequal to the task of dealing with the ever increasing invading forces

We may therefore conclude that the effect of X rays upon diseases of bacterial origin is that they have not any germicidal powers but that *they have a decided inhibitory* effect upon the reproduction and increase of the germs, and that they produce stimulation of the living tissues leading to an increased phagocytosis, which is capable of destroying an unreproductive colony of micro-organisms

A NOTE ON THE REFLEXES IN TETANUS

BY A G GIBSON, M D OXON, F R C P.,

MAJOR, R A M.C, T INSPECTOR FOR TETANUS

THE deep and superficial reflexes are an index of the degree of spasticity in the particular group of muscles concerned in the reflex Elicited with certain precautions the briskness of these reflexes affords considerable assistance in the diagnosis of nervous disease. In tetanus they can be similarly used to ascertain the progress of the disease The muscular reflexes in tetanus tend to be increased in the part affected, and in the more highly spastic muscles clonus can be obtained provided the antagonisers are not in spasm. We know that the chief method of the spread of the toxin is upwards to the spinal cord by means of the lymphatics of the nerve sheaths near the wound, and it is possible by means of daily estimation of the reflexes to demonstrate how the *different groups of muscles become affected* One group of muscles near the area affected may show an increase or diminution of spasticity according as the disease is increasing or decreasing in intensity Thus in one case under treatment with a wound of the right arm the knee-jerks on a certain day were both markedly increased, but much more *so on the side of the wound Three days* later the jerks were still brisk, the right as before, being brisker than the left, and patellar clonus previously absent was elicitable in both legs Six days after both jerks were equal and normal, and there was no clonus In another case with tetanus beginning in the muscles of deglutition the triceps and *biceps jerks on the right side were increased over* the left Many other instances of this might be quoted.

Another reflex of importance is the jaw jerk of the masseter muscle, this is elicitable in all cases where the jaws are moderately stiff, but not in those with tensely closed jaws It can be elicited, as far as my experience goes, at some stage of all cases of tetanus, even *in local* tetanus of a mild grade affecting a lower limb

The clinical points about these reflexes which need to be borne in mind are these The jaw reflex is not usually obtained in normal persons. *The arm jerks* are usually absent but may be present in neurotic patients The reflexes are equal on the two *sides Clonus—i e*, true clonus—when the contractions increase in intensity, is an abnormal phenomenon

The value of a careful examination of the reflexes lies first as a means of confirming the diagnosis especially in a case of local tetanus Such cases are not always easy of diagnosis when one has to take into account the possibility of reflex immobility due to deep suppuration or from implication of a joint especially the hip-joint, and under conditions now prevailing the tetanus inspector is rightly called upon to advise on the least suspicion of the disease, but if with a local spasm of a muscle or a group of muscles another group not in the same region shows increase of tone a diffusible toxin may reasonably be inferred to be acting in the body Its second value lies in the fact that the treatment by antitoxin can be controlled by the effect on the neuro-muscular apparatus Whether or not to give antitoxin by the intrathecal route on the third, fourth, or later day of the disease involving as it does a general anæsthetic, is not *always easy* to decide It may be determined by the general condition of the patient who, if comfortable and without any tendency to spasm might be left till the next day My experience is that there is no relation between the condition of the patient as regards his comfort and the state of his reflexes Daily vigorous antitoxin treatment alone will cause the muscles to relax, and even under daily intrathecal injections of several thousand units the reflexes may increase, and the jaw reflex which previously had been absent may appear My rule of treatment, therefore, is to push the antitoxin treatment by the intrathecal route until the reflexes begin to show normal reactions

AN UNUSUAL FORM OF HYPOSPADIAS

By T J THOMAS, L.M S S.A ,

TEMPORARY SURGEON R.N LATE CASUALTY OFFICER, KING S COLLEGE HOSPITAL, LONDON

THE following curious case seems worthy of record —

A. B , aged 19, came to the sick bay complaining that he had a urethral discharge and pain on micturition On examination he was found to be suffering from acute gonorrhœa He was also found to have rather an unusual form of hypospadias glandis The urethral orifice occupied the position normally occupied by the frænum, looking downwards instead of forwards, but the prepuce was much smaller than is usually found in this condition There was a very small meatal ingrowth ending in a cul-de sac representing the fossa navicularis at the site of the normal urethral opening In addition to the above opening there were two smaller pinhole openings situated symmetrically about one-eighth of an inch to either side of it On probing these two smaller openings they were also found to end in culs-de sac having no communication with anything and being about one-tenth of an inch deep

The gonorrhœa in this case was found to be very difficult to treat, the discharge repeatedly recurring after the patient had been sent to duty, apparently cured On closer examination it was found that a certain amount of the urethral discharge lodged itself in these two small culs-de-sac, setting up a mild local gonorrhœa, which again reinfected the urethra The patient was put to bed and the usual treatment of gonorrhœa adhered to—irrigation, copaiba, &c The urethra was first irrigated with potassium permanganate solution 1 grain to the pint A piece of cyanide gauze was then placed around the urethral orifice and a hypodermic syringe with a smooth blunt needle was employed to irrigate these abnormal openings with potassium permanganate This was done thoroughly, and the openings were then filled with nargol jelly 10 per cent , the meatal ingrowth being similarly treated. This was done morning and evening The patient improved under this treatment, and after four days in bed and *seven days'* quarantine he was discharged to duty with no recurrence as yet

3 *Rules for Recovery from Pulmonary Tuberculosis A Layman s Handbook of Treatment* By LAWRASON BROWN M D Second edition thoroughly revised Philadelphia and New York Lea and Febiger 1916 Pp 184 $1.25 net

1. In this country a concise survey of the pneumothorax treatment of pulmonary tuberculosis has hitherto been lacking, and the busy practitioner has had no handy guide to this treatment its possibilities and limitations its rationale and technique The history of collapse therapy is instructive As Dr Riviere points out it was James Carson, of Liverpool who in a series of physiological essays published in 1821 was the first to urge the trial of pneumothorax in the treatment of disease Another Englishman, Cayley, went a step farther and in 1885 treated a severe case of hæmoptysis by admitting air to the pleural cavity through an incision in the chest wall But from this stage onwards the evolution of the treatment falls to the credit of continental and American workers and it was not till 1910 that it was taken up in England and then only by a small private sanatorium and the inoculation department of a general hospital By this time the treatment had been adopted as a matter of routine in suitable cases by many sanatoriums abroad Though it can hardly be counted unto the chest specialists of this country for righteousness that they have with very few exceptions lagged in the study of the mechanical treatment of the lungs it must be admitted that the inclination to back no runner till the winning post is passed is defensible up to a certain point on the plea that, in the treatment of tuberculosis, there has been such a mob of starters with so deplorably few winners It may be asked Is this treatment a "winner"? The answer is to be sought in Dr Riviere s book Apart from an occasional lapse into the seductive vice of enthusiasm, the author is admirably critical and judicial. The first chapters are devoted to rationale, indications, and contra indications Later chapters deal with apparatus and technique The author is to be congratulated on his preference for plain instruments, the highly complicated apparatus advocated by some operators requires a special training to use it

The section dealing with the accidents that may occur, and how to avoid them, is calculated to place these bogeys in their true perspective , but the author would have done well to have emphasised more clearly the comparative comfort to the patient with which the treatment can be carried out from start to finish To many the very name of the treatment suggests all the horrors of a spontaneous pneumothorax. The term *artificial* pneumothorax is after all about as appropriate as, say, *artificial* venesection Many, if not most, readers will, no doubt, turn first to the concluding chapter in which the author discusses the results of the treatment Here it receives the dubious praise of statistical endorsement More convincing is the quotation from Burnand ' All the physicians who have applied artificial pneumothorax on an adequate scale agree in assigning to it an eminent therapeutic value We have failed to find such unanimity up to now in the appreciation of any other antituberculous remedy, ' which agrees with the author s own verdict in the opening lines of his preface Dr Riviere commends himself to his readers by a literary style as attractive as it is lucid, and the publishers have provided his book with an agreeable setting

2. It is impossible to disagree with Dr Crofton in calling his book on pulmonary tuberculosis a sketch It is indeed sketchy However, it possesses the charm of unconventionality and in matter both of omission and commission the orthodox will find much to challenge On the subject of treatment, for example the author finds graduated labour and sanatorium treatment scarcely worthy of notice, while several pages are devoted to iodine therapy His faith in iodine as an intravital germicide is thus confessed (p 71) "The claims of iodine for this purpose have always appealed to me very strongly For is not an organic preparation of it manufactured in the thyroid?" The author has interesting views on "opotherapy ' Of menstruation he writes (p 104) ' If it is normal (*sic*) or too abundant, testicular substance should be given A combination of adrenalin, pituitrin, thyroid extract, testicular substance and ovarian substance can be obtained commercially, and is one of the most powerful general tonics I know ' Both patients and sanatoria must feel *tempted to* tilt at the author over the following (p 89) "Public (*sic*) patients of Classes I and II may with safety be sent to sanatoria, the other cases are very much better treated in suitable hospitals where they can have the benefit of careful nursing ' The author is convinced that (p 84) "tuberculosis is a mixed infection ' and writing of the microbes *com*plicating pulmonary tuberculosis he says (p 5) "As we shall see later, it is much safer for treatment *purposes to* treat all microbes that grow at 37° C as infecting the patient and not to consider a microbe which has not been described as not being pathogenic ' Whether the microbe has been treated handsomely or *not* the reader, at any rate feels *not* inclined *not* to feel puzzled *not* to say baffled

3 The world is full of dreary little books and pamphlets, veritable Job s comforters up to date, purporting to teach the consumptive his duty to himself and his neighbour But this sorry stuff does not bear comparison with Dr Lawrason Brown's book It is as fresh as the simple life he would have his patients lead Under cover of breezy aphorisms and homely comparisons, the author conveys a wealth of sound advice In fact though the book is written for the perusal of the patient, it contains many a hint which even the author s fellow sanatorium physicians will find new and valuable Endorsing the dictum "Overeating is just as dangerous *as* undereating ' the author dissociates himself emphatically from the Nordrach regime of the dyspeptic ' nineties ' Himself no champion of smoking by the consumptive, he yet holds that tobacco injures fewer men than excess

in eating His words "The path to cure is steep, and is paved with the stones of small details" form an excellent epitome of sanatorium treatment The merits of the book are so obvious that we can even forgive the author for such an amazing statement as this (p 55) "Nearly every tuberculous patient has a more or less deranged nervous system" His parting aphorism "Remember that the porch is the most essential feature of the house" will, it is to be feared, be enjoyed as a paradox, rather than accepted as a truth by many readers, whose observance of it might prolong their lives Dr Lawrason Brown wishes his pages to be used by patients as a hand book of the fundamental principles of the cure, and we think that our readers might well recommend it from this point of view to their charges

---

Hygiene and Public Health By Sir Arthur Whitelegge, K.C B, M D Lond, and Sir George Newman, M D Edin, F R S E Thirteenth edition, revised and enlarged London Cassell and Co 1917 Pp 796 Price 10s 6d net

The new edition of Whitelegge and Newman is a record of six years' progress in preventive medicine and its administration The book still bears the conventional title of hygiene, although it is as much a concise text-book of medicine on its preventive side as Osler, or Taylor, or Wheeler on the remedial side It is in fact, a curious chapter in evolution, that the remedial book should start off with the phenomena of fever or of immunity, followed generally by a topographical grouping of diseases, while the preventive book opens with the primeval elements of air, fire, water, and earth, followed by groups of parasites, large and small, and the spheres of various local authorities It would be stimulating to the reader to consider an arrangement of the two subjects on parallel lines The time is rapidly passing when public health can be considered a branch of medicine to be taken as an extra, or even as a post-graduate, course Prevention must be studied as a matter of course alongside treatment in connexion with each disease and morbid state, and the war, if it has done nothing else, has made this abundantly clear

The present is therefore a peculiarly appropriate time for the appearance of a text-book of preventive medicine, and given the outline as fixed by tradition we have little except praise for the filling in of the details The pages are small, and 800 of them are few in which to include all that is essential in the new without ommitting anything that was good of the old But space has been found for the inclusion of all important legislative and administrative changes The work of the Royal Commission on Venereal Diseases, of the Committee of the Royal Society dealing with food questions, the Mental Deficiency Act of 1913, the National Insurance Act itself, all receive proper notice Such topics as model villages and the health of home workers are discussed The sanitary improvisations of the Army and Navy Medical Services command a chapter which we would gladly have seen longer, and in the application to hygiene of the bully beef tin, in the absence of expensive and complicated engines, we see the future solution of many of the problems of rural hygiene In a few places condensation has led to ambiguity, as in the estimate (p 484) of the action of salvarsan, which might well give the reader too optimistic a view of its rapidity and certainty of result The lessons to be drawn from last summer's experience in America of poliomyelitis in epidemic form in an *urban* area might well have found a place It might be inferred from p 492 that the *prophylactic* dose of tetanus serum is given intrathecally A few actual slips occur, as when TO is confused with old tuberculin—a good reason surely for discarding these misleading initials altogether And are the authors really satisfied that the tubercle bacillus does form spores (p 469)? More serious, perhaps, is the conventional choice of illustrations which group themselves round the rain gauge, the water closet, and the visible parasites The only picture of the spirochæte of syphilis shows nothing Now that the German hand atlas is no more with us, could not a really representative collection of pictorial preventive medicine be issued as a supplement?

A word of commendation should be added for the enterprise of authors and publisher in bringing out a revised edition when both time and material are scarce

Pathology, General and Special, for Students of Medicine By R Tanner Hewlett, M D Lond, F R C P Lond, Professor of Bacteriology in the University of London. Fourth edition London J and A. Churchill 1917 Pp 631 Price 12s 6d net.

In reviewing previous editions of this book we have already commented on the success with which Professor Hewlett has selected and arranged the vast amount of material before him to make a student's text-book. The subject of general pathology is perhaps less bounded by rigid limitations than any other with which the medical student has to deal, and it is well for him when it is largely vital pathology which an author takes as his standpoint and not simply that of the post mortem room and the pathological museum It is five years since the appearance of the last edition of this text-book, years which have added much to our knowledge of such general conditions as shock and collapse, as well as the special conditions due to trench warfare, of which the more important are frost-bite, nephritis, and jaundice, and these have been duly considered in the text The illustrations are well chosen and representative, although we should gladly see all the microscopical preparations done in colour, black and white, however good, gives but an artificial view of a stained section. This is a point, however, which it would ill become us to labour, knowing, as we do from experience, the practical difficulties which attend illustration in colour at the present time. The book is one which may be recommended not only to the student but to the practitioner who wishes to keep correct his perspective of a constantly changing subject

---

The Fundus Oculi of Birds, especially as Viewed by the Ophthalmoscope A Study in Comparative Anatomy and Physiology By Casey Albert Wood Illustrated by 145 drawings in the text and by 61 coloured reproductions of the paintings of Arthur W Head, F Z S Chicago The Lakeside Press. 1917 Pp. 181 Price £3 3s net

The makers of this very beautiful volume—Dr C A Wood, Professor of Ophthalmology in the University of Illinois, and Mr A W Head a Fellow of the Zoological Society of London—are heartily to be congratulated upon the presentation of the results of their investigations For the last ten years they have been engaged upon the quite difficult problem of examining and recording the appearance of the fundus oculi in living, or recently dead, birds Anyone who has tried to use a direct vision ophthalmoscope for the examination of the eye of any lower animal will appreciate the initial difficulties of their task, but with birds there are very special circumstances such as the peculiar action of mydriatics, the presence of a nictitating membrane, and in many cases the minuteness of the eye itself, which increase these difficulties enormously We have personal knowledge of the experiences of a highly accomplished ophthalmologist in the examination of the fundus of a tawny owl, and his account of this adventure increases our admiration for the patient and finished work of the authors

The account of the process of examination is particularly well described by Dr Wood, and his many pieces of practical advice will be of the greatest assistance to those who, stimulated by his example, continue these studies The results, so far as they are capable of being condensed, may be said to embrace an extremely wide field of suggestive conclusions First in scientific appreciation will be the purely physiological findings—the many beautiful co-relations of structure and function determined by this study Again, there are the observations upon the well marked changes which domestication and cage life produce, as well as the deductions as to possible changes of habit in wild birds That many of the findings are useful to the systematist there can be no doubt, and that the similarity of the fundus of the gecko and the apteryx is of great interest cannot be denied, but the *living* side of the work is its greatest merit in our eyes As for the plates, they possess the perfection that one would look for when it is realised that the very best methods of modern colour reproduction have been applied to the work of Mr Arthur Head, whose experience of ophthalmoscopic drawing extends over a period of some 20 years The volume is an extremely beautiful one, and it embodies work which is peculiarly difficult, yet particularly well done

Common Diseases of the Male Urethra By FRANK KIDD, M.B, B C Cantab, F R C S Eng London Longmans, Green, and Co 1917 Pp 132. Price 5s net

THE book is comprised of a series of lectures delivered by the author at the time when venereal clinics were being started under the scheme of the Local Government Board. It is of the type much needed by those unfamiliar with the present-day methods of diagnosis and treatment, which for the most part can only be found in text-books of foreign origin

The lectures primarily deal with the diagnosis and treatment of gonorrhœa in its various stages, so arranged as to emphasise the most important practical methods without any attempt to theorise The methods adopted by the author, after the trial of many others, are, however only mentioned. The important feature in the book, which is everywhere emphasised, is the desirability of defining the exact pathological condition present in each individual case before adopting the requisite treatment, the procedure necessary for obtaining this information is carefully outlined Secondly, the type of treatment necessary for pathological change found and based on such findings is described in detail These two points should strongly appeal to the practitioner who desires to depart from any empirical methods that he has previously adopted The value of urethroscopy, both in diagnosis and treatment, is also duly placed in its proper position Many useful tips for treatment are recorded The book is profusely illustrated. A separate lecture, delivered by Dr P N Panton, dealing with the clinical pathology of the diseases of the urethra is included

At the end of the lectures are four appendices 1 Records of 70 clinical cases each illustrating points of interest 2 The author has embodied his evidence before the Royal Commission on Venereal Diseases It deals with certain statistical information, latency of disease in relation to infection, various complications of the disease, sterility, stricture, the question of marriage and urethritis, and the question of prevention and treatment of the disease as they should in the opinion of the author, be practised There are many points of importance in the report worthy of the consideration of practitioners 3 A description of the author's own room in his private clinic 4 Miscellaneous notes dealing with the complications of the disease

The book should be found useful to all those unfamiliar with present-day methods of dealing with urethritis It can be thoroughly recommended to those whose business it is to work in the newly formed venereal clinics, even if it does nothing more than to stimulate practitioners to define the pathological changes present in their cases

Les Blessures de l'Abdomen By J ABADIE, Surgeon in Chief to the Hôpital d Oran Illustrated Paris Masson et Cie Pp 240 Price 4 francs

IN one small volume Dr Abadie has given a comprehensive account of the surgery of the abdomen in relation to gun shot wounds as practised in France at the present time Professor Faure in his preface comments on the curious fact that whereas in other regions of the body the practice of war surgery has become fairly well standardised, the utmost variety of opinion is still held and forcibly expressed, on the subject of abdominal wounds Dr Abadie's book will help to clear up the discrepancy He deals in succession with the principles the organisation and the technique of abdominal wound surgery summarising clearly and fairly the views of others as well as his own rich experience It is hardly surprising to find that he concludes in regard to penetrating wounds En guerre comme en paix les résultats opératoires confirment qu'il y a bien un traitement de choix des plaies pénétrantes de l abdomen *ce traitement c'est la laparotomie'* The volume is singularly well illustrated in all its sections and cannot fail to interest the British surgeon who will find a useful stimulus in comparing his own methods with those of the author

INSTRUCTION IN HOSPITAL ADMINISTRATION —A three months course of lectures and demonstrations in hospital administration with a view to the requirements of the Diploma in Public Health will be given at the South Eastern Hospital of the Metropolitan Asylums Board (Avonley road New Cross S E 14) by the medical superintendent Dr F M Turner on Tuesdays and Fridays at 5 P M beginning Tuesday Oct 2nd The fee for the course is £3 3 payable to the Metropolitan Asylums Board at the offices of the Board Embankment E C 4

LIBRARY TABLE

SOME WAR BOOKS

FROM a group of books treating primarily of the medical aspects of the war, we select four for notice, which have this in common, that they are graphic descriptions of personal experiences Captain Dolbey's book (*A Regimental Surgeon in War and Prison* By Captain ROBERT V DOLBEY, M B M S Lond, F R C S Eng, R.A.M C London John Murray 1917 Pp 248 5s net) concerns the very early days of the war, narrating the adventures of an officer of the Royal Army Medical Corps with the British Expeditionary Force between August and October, 1914 Captain Dolbey records his work as regimental medical officer in part of the retreat, the advance at the Marne, and in the battles of the Aisne and in the neighbourhood of La Bassée His adventures came to an abrupt conclusion when one October morning he was taken prisoner, and with the wounded under his care, orderlies and stretcher bearers, was imprisoned in Germany The latter chapters of the book tell the tale of Germany as seen by a captive, describe the prisoners' camps at Crefeld, Minden Sennelager, and Gütersloh, and depict what the author calls the nightmare that was the winter of 1914–15 " It is these last chapters which make the historical value of a book which is clearly arranged and well written

Professor Boyd's book (*With a Field Ambulance at Ypres* By WILLIAM BOYD Professor of Pathology, University of Manitoba. Toronto The Musson Book Company, Limited 1916 Pp 111 $1) is a personal diary, kept, as he says, "in the kitchens of French farmhouses, in muddy dug-outs and other unromantic places" The notes date from March, 1915 to August, 1915, and therefore may be read consecutively to Captain Dolbey's book. The views and reflections are communicated with great sincerity and in a quiet intimate style Among them will be found a record of the first gas attack in the war, a note dated April 28th, 1915, running as follows —

> "This morning I had to go to one of the casualty clearing stations, and there I saw a sight which for sheer ghastliness equals anything to be seen in any dressing station The hospital is built around a great courtyard, and in that courtyard were two hundred men on stretchers Some were lying in a state of stupor, the flies buzzing about their faces, some were sitting up gasping for breath, with hands and faces of a deep, dusky hue evidently in the greatest distress, over the countenance of others the pallid hues of death were beginning to creep, whilst a few had fallen back and with gurglings in the throat were passing away into the undiscovered country They were the first gas cases from Ypres and Hill 60 "

A pathetic photograph is appended to the note showing a group of Canadian soldiers who were among the first to suffer from gas poisoning

Miss Agnes M Dixon (*The Canteeners* By AGNES M DIXON London John Murray 1917 Pp 176 3s 6d net) gives a vivid account of life in a French Red Cross canteen not far from the front, where it was her duty to minister now to soldiers moving forward and now to wounded coming back The book is dedicated "To the French *poilu* as I have known him, to his courage, patience, modesty, and chivalry, to his doggedness and grim determination to rid his beloved *patrie* of the foul and cruel invader", and is illustrated with a good many well produced photographs This modest record of hard work done makes pleasant reading because it is infused with the spirit of cheerfulness which has been a marked feature of all Red Cross work The author's profits from the sale will be handed over to the London Committee of the French Red Cross, under whose ægis the "Cantines des Dames Anglaises are established in France

Major Charles Barber (*Besieged in Kut and After* By Major CHARLES H BARBER I M S Edinburgh and London William Blackwood and Sons 1917 Pp 344 5s net) tells the story of the siege of Kut in graphic language His narrative takes us from before the battle of Ctesiphon up to April 29th, 1916, when the place was surrendered all attempts at relief and at victualling having failed It is a sad summary of calculations upset and previsions unrealised from which the courage of those actually engaged in the struggle emerges vividly

The following books (*After War Problems* By the Earl of CROMER, Viscount HALDANE the Bishop of EXETER, Professor ALFRED MARSHALL and Others Edited by WILLIAM HARBUTT DAWSON London George Allen and Unwin, Limited 1917 Pp 366 7*s* 6*d* net —*Proposals for the Prevention of Future Wars* By Viscount BRYCE and Others London George Allen and Unwin, Limited 1*s* net Pp 53 —*The Choice Before Us* By G LOWES DICKINSON London George Allen and Unwin. Pp 274 6*s* —*The Perils of Peace* By CECIL CHESTERTON With an Introduction by HILAIRE BELLOC London T Werner Laurie Pp 239 2*s* net) deal with the purposes, necessities, and perils of militarism and also show the dangers underlying the policy of peace at any price, and they do these things from many different points of view As the title-page shows, the book written by Lord Cromer and his fellow workers is the product of some of our foremost intelligences focussed on the solution of the large problems which the cessation of hostilities will reveal The editor foresees that the new England whatever it becomes, will be the result of long and painful effort, of sacrifice and renunciation Gambetta's watchword is his also "*Le travail, encore le travail, et toujours le travail*" Education, the relation of capital and labour, the land question, the economic future of women, are some of the general subjects debated with freshness and suggestiveness by the writers In the section of Social Reform two more directly medical topics, National Health and the Care of Child Life, are handled by Dr James Kerr and Miss Margaret MacMillan respectively Dr Kerr sees great possibilities of improved national health if the conditions are squarely faced and dealt with on an honest and just basis He deprecates the tinkering with superficial symptoms, and finds that the chief national concern should be healthy maternity and good nursing All services and commodities, he concludes, necessary for public health should be completely controlled by the community in its own interests and for the benefit of all its members Miss MacMillan's plea for the open air nursery school will be read with interest in connexion with Mr Fisher's recent proposals All who wish to help in the solution of the after-war problems should study this book

Lord Bryce and his collaborators suggest a treaty to be established between the great Powers of Europe, the United States, and Japan, agreeing to refer to the existing permanent Court of Arbitration at The Hague, or to the Court of Arbitral Justice proposed at the second Hague Conference—if such a Court is established—or to some other arbitral tribunal, all disputes of a justiciable character, and which the Powers concerned have failed to settle by diplomatic methods Matters of national honour, it is suggested, would also be submitted to arbitrament The prefatory note is dated February, 1915, although publication did not take place till more than two years later The project is a well thought-out one, and quotations from leading statesmen on the subject of international relationships after the war show that the views of the projectors are shared by leading and responsible persons It has become abundantly clear, how ever, to everybody who thinks that proposals for the reform of international relations can have no substantial basis until Germany has been punished for the repudiation of her undertakings—to put her offences against the world at their lowest estimate

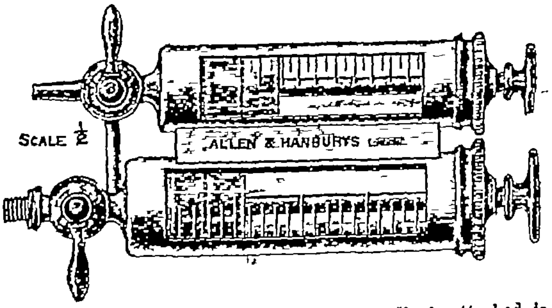
Mr Lowes Dickinson in a plea for internationalism as against militarism would probably not agree that punishment of Germany was necessary, and this it seems to us, is a weak spot in the policy which he advocates, for we have never been able to convince ourselves that punishment is not a deterrent of crime He thinks that all the world may be unfavourably affected by militarism, but he admits that Germany is the leading case Readers are certain to differ according to their estimates of moral values from some of the conclusions of the author, while they are equally certain to agree with others, the paradoxical position of those who attribute the necessity of war to any one cause, such as economic competition or growth of population, is neatly exposed

It is stated on the cover of Mr Cecil Chesterton's book that it shows conclusively "that any peace which leaves the present German Empire in existence with its centre in Berlin would be a mere truce" The book fails to do anything of the sort, but there is sense in some of what the author says

New Inventions.

A DOUBLE-BARRELLED SYRINGE

THE double barrelled syringe shown in the illustration is made in two sizes—one to hold 2 cubic centimetres and the other to hold 20 cubic centimetres The object of the smaller syringe is to inject a little saline from one barrel after the drug has been injected intramuscularly from the other barrel thus preventing a track being made during the withdrawal of the needle The mercury, or whatever drug is being injected, is thus prevented from getting into the subcutaneous tissue and producing an abscess or an indurated lump A local anæsthetic can be given before the drug is injected intramuscularly without having to make two pricks The larger syringe is for intravenous or for intraspinal work.



If the left-hand barrel, to which the needle is attached is filled with the solution to be injected, after inserting the needle into the vein, as much blood may be withdrawn into the right-hand barrel, emptied into a receptacle, and refilled as often as desired, before or after the drug is injected. When injecting colloids it is a good plan to let the blood mix well with the colloidal suspension before it is injected, a manœuvre which can be well carried out with this double barrelled syringe As the right-hand barrel can always be filled and refilled with a solution from a receptacle underneath, and the contents discharged into the left-hand barrel, a dilute as well as a concentrated intravenous injection may be given Another advantage is, that the right-hand barrel may be filled with a calcium chloride, glucose, and gelatin mixture, which can be injected through the same needle before the contents of the left-hand barrel are discharged, to prevent shock, or after should symptoms of shock threaten.

They are made by Messrs Allen and Hanburys, Limited, 48, Wigmore street, London, W 1

A NEW FRACTURE SUSPENSION APPARATUS

WE examined recently a new method of slinging fractured limbs at the McCaul Hospital for Officers, 52, Welbeck street, W The apparatus the "Hammock Suspension for Fractures," was devised by Miss Gasetti, a Frenchwoman Essentially it

The apparatus is simple and inexpensive can be bolted to consists of a frame made of wood, which than those forms any bed, becoming thus more widely useful The frame is of apparatus which need a special bedstead four or five feet, quadrilateral and is held above the bed some are fastened pulleys and to this rectangular horizontal frame the injured limb is sus through which run cords from which to carefully adjusted pended, these cords are attached also the weight of the counterweights which just counterbalance the patient wishes to injured limb and splints, so that when very slight force and move the broken limb the cords give to The apparatus also the limb has the minimum of disturbance so adjusted as not provides for extension, and this can be movements of the limb to interfere with the position and of the limb, a matter The apparatus allows also for abduction at the upper end sometimes of great importance in fractures of a transverse bar of the femur This is effected by means beyond the end of the reaching outwards for a foot or two extension cord works is bed, the pulley over which the is necessary from the fastened to this transverse rod as far as of abduction needed middle line, according to the amount adapted for its purpose The apparatus struck us as admirably

OPOLAXYL

Rational Treatment of Constipation

By the double action of secretions and peristalsis

Opolaxyl is a combination of the secretions of the liver (biliary), pancreas and intestines, with vegetable extract of a non-drastic nature

It combines all the secretions to correspond to nature's therapy and promotes a flow of bile and glycogen

It is a normal regulator of the gastro-intestinal functions, consequently it improves the metabolic exchanges of the entire organism

Opolaxyl does not lose its efficacy by prolonged use, its effect is gentle and constant, with the least irritation It is not merely purgative, it stimulates the defective organs and revives the normal equilibrium, it has a lasting effect because it rebuilds the organs, thus correcting diminutional function

Opolaxyl is put up in small size tabular form, and should be swallowed without crunching at bedtime or before breakfast.

***DOSE*·**

For obstinate constipation 2 or 3 tablets, afterwards
1 tablet every 3 or 4 days for a month

URASEPTINE

The Most Powerful and Effective Urinary Antiseptic.

URASEPTINE is a granulated product entirely soluble in water, its bases being **Piperazine, Urotropine, Helmitol, Benzoates of Sodium and Lithium** It contains 60 centigrams (10 grs) of active matter to each teaspoonful

Dose.—2 to 6 teaspoonfuls daily

It purifies the Urine, and this action is due to its three principal properties

1 It is a URINARY ANTISEPTIC.
2 A SOLVENT of URIC ACID and of PHOSPHATES.
3 A MILD NON-TOXIC DIURETIC.

INDICATIONS—**Arthritism, Gout, Gravel, Hepatic and Renal Colic, Rheumatism, Calculus, &c, Phosphaturia, Urinary Antisepsis, Pyelitis, Bacteriuria, Cystitis, Prostatitis, Urethritis, Pyuria, Urinary Abscess, Vesical Catarrh, &c**

A Great Advance in the Treatment of* BURNS*—Slight or Severe

AMBRINE

Ambrine is *the only Authorised preparation* of Dr Barthe de Sandfort
We are compelled to state this as there are various imitations

Ambrine forms a dressing which INSTANTLY alleviates pain—promotes rapid healing—forms a sure protection against infection of the wound—can be removed without pain hæmorrhage, or injury to the newly formed tissues The healing leaves no scars or contractions

The most efficient means and method of ensuring active **Hyperthermal Therapy** to the practical treatment of **Rheumatism, Gout, Arthritis, Varicose Ulcers,** and similar affections

May be applied with camel hair brush, but our specially designed spray greatly facilitates the application of Ambrine, especially in the case of deep wounds or extensive surfaces

THE LANCET, June 10th, 1916 —

The Value of Ambrine in the Treatment of Wounds

Attention is being drawn to the remarkable success of the Ambrine Wax treatment now being used at the Hôpital St Nicolas at Issy les Moulineaux for burns frozen feet and all wounds where the tissues have been so damaged as to exact great length of time and considerable disfigurement in their resolution by the usual means The Minister of War in reply to the Deputy M Mons as to why in view of the marvellous results obtained by treating burns and frost bites with Ambrine at the Hôpital St Nicolas all the soldiers suffering from such wounds were not sent there stated that this was being done as far as possible ...

Medical Treatment of CANCER.

CUPRASE

Cuprase is a colloidal Copper hydroxide which is obtained chemically by the reduction of Salts of Copper in the presence of Albumosic Acid

The numerous clinical reports from Doctors of repute in various countries give cases of a great variety In all of these pain has been eliminated, and in a good percentage cures are claimed, and in no instance any undesirable effects

Its *easy application* (subcutaneous injections) places it within the reach of all practitioners It *is not toxic*

Disappearance of the Pain

Return of Sleep

Increase of Appetite

Colour and Strength

Warwickshire, July 1st 1917

Dear Sirs—Will you please send me another box of Cuprase ampoules The previous lot effected a most remarkable cure in an elderly lady suffering from cervical cancer—the cauliflower like growth has disappeared with its offensive discharge

This case was given three months life by a Specialist being inoperable

Yours faithfully
(Signed) B—— B—— M R C S L R C P

"SANITAS"

ANTISEPTIC JELLY

A combination of "**SANITAS OIL**"—active principle Camphoric Peroxide—with a pure hydrocarbon

For application as an unctuous dressing for torpid Wounds and Ulcers, and for Stings of all descriptions

Medical Reports are to the effect that "**SANITAS JELLY**" is very useful—

- For "sore nipples"
- For anointing fingers in midwifery cases, and making examinations
- For eczema in the dry stage
- For treatment of old and torpid Ulcers and Wounds
- For treatment of open wounds just beyond the need of hot fomentations

In 1/- and 3/6 Pots

The "SANITAS" CO., Ltd.,

LIMEHOUSE, LONDON, E. 14.

Disinfectant Manufacturers, by Appointment, to H M THE KING

"Semprolin" Emulsion with Iron

THIS preparation admits the administration of iron *for long periods* without digestive disturbance or constipation The iron, being in colloid form, is quickly and easily assimilated With Liquid Paraffin no habit is induced as with purgatives such as cascara, aloin, &c Gives excellent results in Anæmia, &c

In 8 oz and 16 oz Bottles

CONTAINING

Dialysed Iron	**20 minims**
Russian Liquid Paraffin, B P	**55%**

in each tablespoonful

Reconstruction.

AT a recent meeting of the medical profession at Edinburgh a unanimous resolution was passed to the effect that the circumstances in which the medical profession is placed "made it impossible effectively to consider any scheme before the end of the war for the establishment of a Ministry of Health," and this is a view which has for its support so many obviously sound arguments that it must be seriously considered. The medical profession has given over a quarter of its total, and the most effective quarter, to the country for the purposes of the war, and though some of these men are returning to civil life others are taking their places and must continue to do so for some undefined period. As officers in the Navy and Army their opportunities for even expressing their opinions are very restricted, and as to backing those opinions by action of any sort there can be no question at all. Numbering among them men whose professional work entitles them to give counsel to their colleagues and to the country on all points in the administration of medical service, they will remain largely out of any discussions, professional or other, of the difficulties that may arise during the formation of a Ministry of Health. Yet on their return they will be confronted with the results. On the other hand, there is no doubt that for the medical profession to adopt a do-nothing attitude would be to risk the creation by lay authorities of a scheme that would not be agreeable to members of the medical profession remaining at home, and which might press hardly on certain of that large proportion of practitioners whose interests, in their absence from their usual duties, it is proposed to defend by resisting active innovations at the moment. Here again we have a point of view based on arguments which cannot lightly be dismissed, for it is quite certain that a Ministry of Health uninspired by the ideals of the class that will constitute not only its official leaders, but its rank and file may fall sadly away from that standard of efficiency which is necessary for the justification of its genesis.

The difficulty in this situation of ascertaining on which side truth lies is a difficulty which is not peculiar to the medical profession. The medical profession has somewhat slowly begun to regard itself, and to be regarded by others, not as a thing apart from the sociology of the general population, but rather as a section of that population more intimately concerned with general welfare than is any other section, and the problem before us is before the nation as a whole with regard to all national activity. The war has lasted longer than was anticipated, and its duration may still disappoint sanguine expectations, for many of the theories regarding failure of resources and exhaustion of money are now seen to be false almost in direct proportion to the confidence with which they were enunciated three years ago. And it must be remembered that after the war is officially over an appreciable time may elapse before any free development of social life takes place. Now during all this period, of undetermined length, civilisation must not be allowed to stand still, and, if possible, it must progress in spite of the disabilities. And while, on the one hand, the days in which we live seem very inopportune for the promotion of social reforms, owing to the fact that those who would necessarily lead the movements, whether individual or collective, are so deeply engaged in fighting the Germans as to have no spare time or energy—on the other hand, these are days when great changes can be advocated and effected without creating any of the opposition which their mere suggestion would have aroused before the world's upheaval. If the policy of waiting has its advantages the same can be said for the policy of action. We must not make too much of the drawbacks attendant on revisions of our social scheme while some people are unable to play what would otherwise have been a leading part in reform, for, despite the support and guidance from sources whence they might be expected, men naturally reactionary will lean towards the cause of reform, if only through the feeling that a civilisation which has let the world in for such a welter of horrors can, perchance, be amended in many particulars.

The formation of a National Party to take the place of political parties has been objected to on the ground that this is not the time for clearing up the mess of our political system, and contrariwise the creation of a National Party has been advocated on the ground that there is much work to be done now if we are to progress in the immediate future. We see therefore that the medical profession, an integral part of the social scheme, is in a position which exemplifies our present national conditions, and what is good for the country will be good for medicine. We think that some reconstruction work should be thought out now, but that is not the same as saying that, in the absence of over 10,000 medical men—with many of our leaders in this category—from the practice of their profession schemes radically altering the condition of that practice should be put in hand. Yet no one can fail to see that medical practice has inevitably been profoundly altered by the war. We should like to learn of the formation of a board, comparable in some ways to the Ministry of Reconstruction over which Dr. ADDISON presides, whose prime function should be to think. The members of the board could be largely spared the task of collecting facts, for the General Medical Council, the great medical corporations and medical faculties of Universities, the Government Departments having medical affairs in their charge, the British Medical Association, the leading medical charities, and the medical press can between them supply all needful information. But the interpretation of the facts thus obtained may well require close attention from persons intimate with the details of medical education, scientific work, and professional life, and this would be ensured by the formation of a strong board, and to this board the representatives of the medical men now serving in the Navy and Army, with their good perspective of home affairs, would contribute materially

The Pathology of War Nephritis

LAST week we referred to the etiology of certain obscure war diseases This week two articles on War Nephritis give occasion for a return to the subject In one of these, which we print on another page, Captain C E SUNDELL and Captain A T NANKIVELL state the results of their study of 250 cases which have come under their personal notice In the main they confirm the clinical observations of previous writers, but they come to a different conclusion as to the etiology of war nephritis They suggest that the disease is caused by some error of metabolism due to a dietetic deficiency If this is so, the rarity of nephritis in the South African War is certainly surprising, since all the dietetic deficiencies referred to by the authors were existent then, and in a higher degree than in the present war Restricted diet has been common in war, but nephritis has been rare The authors note that the disease was very rare among the Indian troops, but Indians are also comparatively immune from scarlet fever Some observers hold that the infective agent in war nephritis is an organism allied to that causing scarlet fever, and if Indians are immune from one they might be immune from the other The comparative rarity of nephritis among officers is curious, though less marked than it was, but, as the authors point out, nephritis does occur among hospital nurses, in whom a condition allied to scurvy—suggested as a cause—is not likely to arise Several of their interesting pathological observations might be held to confirm the observations of others who have come to different conclusions Thus they find that the blood counts were typical of the so called protozoal diseases An animal ultra microscopic virus was suggested as the cause by Captain W LANGDON BROWN (of whose work the authors appear to be unaware) in the *Journal of the Royal Army Medical Corps* for July, 1915 Their observation that the glomeruli were almost entirely destroyed or filled with endothelial plugs, and that the kidney lesion is focal rather than diffuse would tend to support Captain J S DUNN's views of the embolic nature of the nephritis It is unlike anything that has been described in the kidney in scurvy

In the second article, appearing in the April number of the *Canadian Medical Association Journal*, Professor RUDOLF has summarised his experiences of war nephritis Although his clinical observations are in accord with those of Captain SUNDELL and Captain NANKIVELL his conclusions are different, for he states that the disease appears to be due to some infection, local or general, the nature of which has not been determined, but probably of the ultra microscopic variety In general he supports Captain LANGDON BROWN's views He draws attention to the epidemic character of the disease comparing it with the epidemic in the American Civil War Like other observers, he is impressed with the low mortality rate and the frequency of nocturnal dyspnœa, which he regards as distinguishing characters of this as opposed to other forms of nephritis Two forms of protozoal disease, new to Europe at any rate, have been held responsible for widespread epidemics of low mortality in this war —namely, the hæmogregarine of trench fever and the spirochæte of epidemic jaundice It seems probable on the evidence available that a third organism of this kind may be responsible for war nephritis The strongest argument adduced against an infective theory is that of Captain DUNN, who points out that the disease is almost unknown among the civil population in France, although living in very intimate relation with the military On the other hand, we have to account for the cases among nurses and orderlies in base hospitals in France who come into close contact with the patients at an early stage of the disease It is difficult to see how a dietetic factor could account for the entire absence of the disease from the training camps in England The analysis of the literature of war nephritis, published last May by the Medical Research Committee, gives to all who are interested a ready opportunity of studying the subject further

Annotations.

"Ne quid nimis"

THE ROYAL SOCIETY OF MEDICINE

AT the recent annual general meeting of Fellows of the Royal Society of Medicine attention was called to the resignation of the first editor of the *Proceedings* and Mr J Y W MacAlister's offer to assume the duties without any addition to his salary This offer the Council had gladly accepted, and the acknowledgment of Dr Charlton Briscoe, honorary secretary of the society, of the large debt owed to Mr MacAlister for his gratuitous services was warmly received Dr Farquhar Buzzard (acting honorary treasurer) presented the balance sheet for the year ending September, 1916, showing a balance of income over expenditure for the year of about £1000, but the number of Fellows has decreased and their subscriptions still more, making it advisable to increase the number of Fellows as far as possible, while, on the other hand, there has been a general increase in expenditure common to all bodies and persons at present The President of the society, Sir Rickman Godlee recalled the work done by the Emergency Surgical Aid Corps, which is called out by the police and War Office whenever an air raid takes place in London This corps is supported altogether by the voluntary contributions of its own members, who on many occasions have spent tedious hours of waiting in the night, besides rendering considerable service He also commented on the new feature which Mr MacAlister had added to the *Proceedings* under the title of "Notes on Books" These notes which are quite short have been made by various members during the reading of the books They consist of a few lines indicating the contents with accuracy and publishers have been found willing to present books on the understanding that they shall receive this amount of publicity A good number of Fellows have helped in the work, but more would be welcome, and they are invited to tell the secretary the kind of book they wish to receive The President reported that Dr C G Cumston, of Geneva, a Fellow and a member of the Section of the History of Medicine had intimated his intention to bequeath a sum of £17,000 to the society, the income to provide for lectures on the history of medicine and additions to the society's library on that and other subjects A vote of thanks was passed to the President for his address and for his valuable services during the past year, and the best thanks of the society were voted to the retiring Vice Presidents and retiring members of the Council for their services during their terms of office Dr Maurice Craig moved a cordial vote of congratulation and thanks to Mr MacAlister on the completion of 30 years of service to the Society, together with an earnest hope that his health may permit him to continue his work for many years to come This was seconded and heartily endorsed by the President and carried by acclamation Mr MacAlister responded, "I can only say thank you, Sir, and Fellows all. At the end of the next 30 years I shall perhaps have more to say"

HAY FEVER PLANTS IN THE UNITED STATES

IN the Eastern States of America 84 per cent of the cases of autumnal hay fever are attributed to the pollen of the common ragweed, *Ambrosia elatior*, while the grasses, both wild and cultivated, are blamed for the early and less serious form *A elatior*, or ragweed, is not to be confused with the gorgeous yellow ragwort Its pollen is only 15 μ in diameter, and with a spiculated surface increasing its buoyancy by one half, has been shown to travel several miles in a moderate wind Dr William Scheppegrell, who has devoted much attention to the causes of hay fever, writes in No 29 of the U S Public Health Reports on the flowers which have been incriminated in the Western States where the ragweeds are rare All hay fever plants are wind pollinated, which means that they bear inconspicuous flowers without bright colour or scent, and produce large quantities of pollen He has employed the biological test, which consists in applying a weak saline extract (1 20 000) of the pollen to the nasal mucous membrane, gradually raising the strength until a reaction occurs A conjunctival or skin test may also be applied Some pollens are intensely irritating, the Californian mugwort *Artemisia heterophylla*, produces a reaction even in a dilution of 1 100 000 On the whole, it is the genera *Artemisia Iva*, and *Gærtneria* which account for most of the cases and while prevention is rendered more difficult owing to the variety and great prevalence of the plants concerned, it is not insurmountable, inasmuch as the pollen of these plants is much heavier than that of *Ambrosia*, and their range of wind distribution not more than one sixth The education of the public in the noxiousness of these weeds is according to Dr Scheppegrell the important matter when suitable legislation will be enacted New Orleans has already, in its grass weeds ordinance, legislated in regard to the causes of the vernal fever

THE METROPOLITAN WATER-SUPPLY

ACCORDING to the reports to hand, the rainfall at 12 stations which have been selected as giving equal representation for all parts of the Thames basin during the months of April, May, and June was above the average mean for those months as recorded for the previous 34 years In April it was 0 24 inch above, in May 0 30 inch, and in June 0 22 inch The work of filtration proceeds satisfactorily, as all the samples collected at the different works were, generally speaking, clear, bright, and free from suspended matter In some respects the chemical quality of the raw river waters in April and May was worse or showed little change compared with their averages, but in June the results were generally better All the raw river waters contained, however fewer bacteria than their respective averages for the year 1916, while all the filtered waters, generally speaking, yielded not unsatisfactory results, from 71 4 (June) to 97 4 (April) per cent of the samples containing no typical *B coli* in 100 cubic centimetres examined

INDIGENOUS MALARIA IN ENGLAND

AN interesting case of malaria acquired in England, by a soldier, aged 20, who had never been out of the British Isles was reported in THE LANCET of August 4th last by Captain A C D Firth. Other cases of the same nature have been detected during the last few months especially amongst the troops stationed in and near Aldershot The return to England of large numbers of men who have had malaria in the Eastern campaigns involves the presence among certain military populations, and to some extent among the civil population generally, of persons who carry in their blood the parasite of malaria Information as to the prevalence of different kinds of mosquitoes in England is by no means complete, but there is no doubt that in certain areas in the south and east, particularly those where marsh fever or ague was common up to the earlier part of last century, anopheline mosquitoes, particularly *A maculipennis*, are still met with and are occasionally abundant Towards the end of last month weather conditions seem to have favoured the production of swarms of mosquitoes in many places, some of which have undoubtedly included anophelines In these circumstances measures to limit possible malaria infection are clearly required, and we understand that they have been taken very thoroughly by the War Office, which, with the advice of Sir Ronald Ross has made arrangements for the segregation of known cases of malaria in special depôts and hospitals for the continued administration of quinine in the case of all soldiers who are likely to remain carriers of malaria, and for various other precautions to be taken As regards the civil population the Local Government Board has instituted inquiries, through the medical officers of health of districts likely to be affected for the existence of indigenous cases of malaria and has supplied these officers with a memorandum on the subject to be circulated to medical men practising in their areas It is there urged that medical practitioners should keep the medical officer of health informed of any cases of fever occurring in their practice shown or suspected to be due to malaria, in order that inquiries may be made as to possible sources of infection The memorandum further states that the department has made arrangements whereby specimens of blood will be examined and reported on free of charge, if sent, according to instructions, to the medical officer of the Board at Whitehall It seems probable that only a small number of sporadic cases will be heard of, and with the near approach of weather conditions fatal to the adult anopheline such risk as now exists should not long continue But in view of possible future developments it is of great importance that all available facts should be ascertained, and that the possibility of malaria should be kept well in mind when anomalous or unusual febrile attacks are met with, especially near large military centres which are situated close to marshy and low lying areas The liability of children to this disease should also be remembered

ADOLF VON BAEYER

Professor Adolf von Baeyer, whose death in Munich was announced last week, was prominent among the founders of Germany's chemical industry His early studies were devoted to the constitution of complex molecules, and much of our knowledge of the architecture of organic compounds is due to his brilliant investigations His work, though at first of a purely scientific character, soon found industrial application, and a trade in synthetics was set up His greatest achievement, perhaps, was the preparation of synthetic indigo with naphthalene in one case and benzene in another as a starting point The process, after the expenditure of very large sums of money, was acquired by the Badische Anilin und Soda Fabrik at Ludwigshafen, which is quite distinct from the Farbenfabriken of F Bayer and Co at Elberfeld—also a very large concern Adolf von Baeyer was born in Berlin in 1835, and was a pupil of Bunsen and Kekulé In 1860 he became assistant professor in Berlin at the technical college, then from 1872–1875 in Strassburg, and lastly the head of the university laboratory at Munich, the famous Liebig's chair

THE NUTRITIVE VALUE OF BEER

THAT the direct food value of beer counts for little is borne out by an interesting investigation carried out by J S Sharpe in the department of physiology, Glasgow University, the results of which are published in the August number of the *Biochemical Journal* It cannot be denied that the alcohols, sugars, and dextrin have a certain value as sources of energy, but even if we reckon that the total nitrogen found is present as nutritive material still the amount is insignificant But, as Mr Sharpe shows, it is a mistake to assume that all the nitrogen present is in the form of protein As a matter of fact, the protein nitrogen of the beers he analysed varies from only 13 2 to 37 per cent of the total nitrogen—that is to say, the protein content of beer varies from 0 038 to 0 185 per cent, quite insignificant figures In regard to the further distribution of nitrogen in beer, the amino acid nitrogen varies from 0 014 to 0 040 per cent, nitrogen in purins from 0 010 to 0 039 per cent, and amounts due to other substances as alkaloid and bases are quite negligible These results are of interest, especially in view of the report of the Committee of the Royal Society on the Food Supply of the United Kingdom, which stated that the nitrogen compounds of beer have been little studied So incomplete is our knowledge of their nature that this committee did no more than assume that something between 50 and 100 per cent of the nitrogen in beer is in the form of protein or amino acids which are utilisable in the body The higher gravity beers, as might be expected, show a higher nitrogen value than the low gravity beers, but is not all this beside the point? Beer is consumed because it is to so many a pleasant and palatable beverage The thirsty man pays no regard to the food value of beer, he looks upon it as a pleasant, refreshing drink, and he is right, and it is fallacious once and for all to justify its consumption on the cult of calories or "tissue formers" There is, however, one point overlooked in regard to the rôle of beer in the dietary It contains a material amount of diet deficiency substances of the order of vitamines, and investigations have shown that beer added to the dietary increased the assimilation of non nitrogenous foodstuffs, and particularly of fats, while alcohol in moderate amount increased protein absorption from nitrogenous foods Then, again, beer has undoubtedly a condimental action and often makes the simple meal attractive, if it is only bread and cheese Thus regarded, beer, instead of representing a waste of food materials from which it is made, may actually effect an economy in inducing in those whose custom it is to drink it a better appropriation of the food they consume In the recent bitter controversy about the merits and demerits of beer this consideration should not be left out of the equation, in justice to beer drinkers who are modest in their demands for the national beverage

---

WE draw our readers' attention to the appeal of the War Emergency Fund of the Royal Medical Benevolent Fund, a second list of contributions to which appears in our advertisement columns The fund is intended to coördinate and supplement the other existing agencies concerned with the material prospects of the medical man who has made sacrifices for his country Those responsible for its administration are determined that it shall help, and help effectively, needs which can be met in no other way

---

THE Ministry of Food is itself a novelty and has taken the novel course of issuing an official journal The first number of the *National Food Journal* appears this week, and the breaking of the customary reticence of a Government Department is, in this instance at all events, a matter for congratulation, for the journal should be a persistent weapon in the campaign of food economy

---

NEWS has been received from Dublin of the sudden death of Dr Frederic William Kidd, who occupied for many years the Chair of Midwifery at the Royal College of Surgeons in Ireland and was an ex Master of the Coombe Lying in Hospital

---

FOREIGN ORDERS AND DECORATIONS —The King has granted unrestricted permission to the undermentioned medical men to wear decorations conferred upon them respectively by the Russian Government, in recognition of the services which they have rendered to the Russian sick and wounded under the auspices of the British Red Cross Society and the Order of St John of Jerusalem in England Dr Frank G Clemow, C M G, has received the Order of St Anne, Class 2, with Swords, Dr Edward M Hime the Order of St Stanislas, Class 2, and Mr Alfred E Hind the Order of St Anne, Class 3

THE BIOLOGICAL ASPECTS OF WARFARE

BY HARRY CAMPBELL, M D LOND, F.R C.P LOND,
PHYSICIAN TO THE WEST END HOSPITAL FOR NERVOUS DISEASES LONDON

I

The Function of the Combative Instinct

FROM the biological standpoint the combative instinct is to be regarded as a normal mental attribute, not as a quality to be condemned offhand as something which the world would be all the better without That it has existed for a useful purpose is shown by its universality among all but the lowest animal organisms and by the fact that special weapons of offence and defence in the shape of horns, tusks, claws, and the like have evolved to give effect to it Some measure of combativeness is obviously necessary for all the vertebrates and many of the invertebrates in the struggle for existence, for a creature without some self assertiveness, some show of fight would be at a distinct disadvantage in that struggle. The primary object of this instinct is to enable an animal to get the better of a rival by direct encounter The emotion attaching to it is anger—the most violent, be it noticed, of all the emotions This emotion, unless controlled, causes the combatant to assume a ferocious aspect—to show the teeth, erect the hairs, and to utter terrifying sounds all with the object of cowing the opponent—while at the same time it has the effect of liberating the flood of muscular energy needful for the ferocity of onslaught which makes for success Although unbridled rage is helpful in fight among the lower animals, needless to say it is the reverse of serviceable in the deliberate fighting of man against man, as in boxing and fencing, for here anger interferes with those cautious methods of attack and defence which are essential to success To lose one's temper in fighting of this kind may be to lose the fight With this reservation it is curious to note the close kinship between the combatant instinct of man and of the lower animals The untamed man when enraged assumes in very truth the aspect of the tiger he puts himself in a threatening attitude, frowns, glares rolls his eyes, grinds his teeth, snarls growls or even roars—thus instinctively seeking to strike terror into his opponent The raising of the voice in anger is manifestly akin to the roar of the angry carnivora Darwin has pointed out the connexion between the human sneer and the snarl of the angry dog, and I have myself seen a refined woman in a transport of spite lift her upper lip and show her teeth in a manner absurdly like an enraged beast But nothing shows more clearly the essential identity of the fighting instinct in man and the lower animals than the way in which a child, soon after it can toddle will rush at the object of its passion and proceed to bite and scratch, i.e to use teeth and claws as any of the carnivora might It would be interesting to know how far the grimacing habit of children is related to the combative instinct A child protrudes its tongue and contorts its features in order, it would seem, to express dislike and defiance

The primary object of anger, rooted as it is in the fighting instinct is to prompt to combat This is its natural goal The emotion may however fail to realise itself in the natural way owing to the operation of restraining influences Such a one is fear—in the case of the lower animals practically the only one In the case of man, other inhibitory influences come into play The normal civilised man even when in a tempest of passion is able by an effort of will to restrain himself from venting his rage by the primitive method of personal assault

Now among the causes of anger pain especially when it can be referred to an external source takes a prominent place This, we may suppose is because among the lower animals pain is frequently caused by the attack of another animal The animal attacked is roused by the pain inflicted to retaliate upon the aggressor and every additional pang sustained in the course of the encounter intensifies the fury which makes for success In order that it may excite to fury the pain must not however be too intense for in that case it may have a paralysing numbing effect robbing the combatant of courage and prompting to hasty retreat This cowing effect of pain is made use of in training unruly animals human and other

The tendency to retaliate upon an object causing pain does no always display itself in a rational way There is a disposition to vent rage, e g, upon the innocent bearer of bad news or even upon inanimate objects thus a man who hurts himself against an object may have an irresistible impulse to kick that object, just as a dog bites at the stick which is lifted against him, similarly, an undisciplined person may in a transport of passion relieve his feelings by smashing all the breakable articles within reach

The effects of anger which realises itself in actual assault being to injure and to inflict pain, the question arises how far the assailant derives satisfaction from the injury and pain which he inflicts Here we find a striking contrast between man and the lower animals—and not to the credit of the former The sub-human animal has no conscious desire to inflict pain upon the object of its rage, it is just impelled by blind instinct to make a destructive onslaught upon it The like is true of the child who scratches and bites the person annoying it The child—the young child at least—*does not form* a definite idea of inflicting pain and then proceed deliberately to put it into effect When, however, *the stage of self-consciousness* is reached, anger may beget a definite desire to hurt the object *of* it, and if *this does* not find vent in the primitive way of inflicting some bodily injury, it may seek satisfaction by causing pain in other ways as by taunts, jeers, scoldings, or long and deep laid plans of revenge

Here we touch upon what is perhaps the basest of all vices—cruelty A cruel person is one who exults in the pain, mental or bodily suffered by another Cruelty has its basis in anger (and thus is related to the combative instinct), though there is a cold blooded form of cruelty which may be enjoyed without any obtrusive feeling of anger Cruelty, implying as it does self consciousness—the ability to realise the feelings of others—is essentially a human attribute Children who impale frogs and eviscerate flies cannot be said to be cruel, for they know not what they do Nor are the lower animals cruel, seeing that they are wholly unconscious of the sufferings of others Thus the charge of cruelty against the carnivora is unjust These animals generally destroy their victims outright and in the rare cases (e g cat and mouse) where they prolong the suffering they have no knowledge of the pain they are causing When therefore we stigmatise the conduct of the cruel man as "brutal,' we wrong the brutes The animal which attacks another and in so doing causes pain merely responds to a blind unthinking instinct, but man, proud man, who looks before and after is able to realise and take pleasure in the pain he deliberately and by subtle means maybe, sets out to cause It is clearly absurd to speak of his conduct as 'brutal" Rather should we call it devilish, the Devil usually being credited with a goodly share of intelligence We must cease to libel the brutes by designating the basest acts of man as brutal As a matter of fact, they cannot be charged with non moral conduct, seeing that they are devoid of self consciousness

Spite, vindictiveness and actual revenge are all forms of cruelty and thus are rooted in the combative instinct, and so too is hatred which is a kind of persistent anger directed on a particular object Irritability and querulousness are minor manifestations of the same instinct But while some of the worst of man's vices are derived from the fighting instinct so also are some of his best qualities The primitive desire to get the better of another has found expression not in violence alone but in that hearty *spirit of* emulation which is essential to progress and anger in the form of righteous indignation has through the ages moved men altruistically we feel a touch of the sufferings of others and some measure of the anger and the impulse to retaliate which actual experience of these sufferings would excite in ourselves Here, indeed is the source of all our reforms

The Evolution of the Combative Instinct

Two important factors have favoured the evolution of the combative instinct (1) the reproductive instinct, and (2) the struggle for food.

1 Among polygamous species the males, as is well known fight furiously for the possession of the females To aid them in these encounters they are provided with special weapons which (as in the case of the horns of the stag) may only attain full development, and only remain fully serviceable at the breeding season At this time, too animals otherwise docile, may become dangerously aggressive In the case of the female also the combative instinct is employed in the service of the reproductive

function A cat in charge of her kittens will, when danger threatens them, be roused from the tender maternal mood to sudden fury in their defence Here we see the most opposed of all emotional states—love and anger—alike called forth at the bidding of the reproductive instinct Let us not fail duly to appreciate the fact that one and the same individual is endowed with such opposite potentialities I shall return to this point presently

2 The combative instinct is helpful in the food struggle How close is the relation of the one to the other is shown by the effect of hunger the hungry beast is wont to be savage, and the hungry man is proverbially apt to display, in an attenuated form no doubt, some of the ferocity of the hungry beast, after a good meal he subsides into an amiable, pliant mood Even animals usually gentle scramble and fight among themselves for food, but it is among the carnivora especially that the food struggle has developed the spirit of combativeness, and it is, as we shall see, largely on account of his carnivorous propensities that man has grown to be the terrible fighter which in point of fact he is It is true that the carnivora do not ordinarily need to fight their comparatively defenceless prey, but there can be no doubt that the instinct that leads them to seek out and destroy their prey is largely based upon and aided by the combative instinct It must have been a combative impulse which led the first carnivorous mammal to attack its first victim, and this instinct must be of use in enabling the assailant to overcome an unusually doughty opponent As a matter of fact, all the carnivora are ferocious It may be pointed out in passing that the appearance of the carnivora upon the scene has probably had some influence in generating a spirit of combativeness in the species they prey upon, in that some degree of pugnacity is of service to the latter in helping them, especially if acting in combination with others, to resist their assailants

The fact that carnivorism makes for ferocity and develops the fighting instinct has this interest—that man is himself carnivorous Indeed, in the matter of slaughter he leaves all other animals far behind He is the arch slaughterer—*facile princeps* Since the time the pre-human ape took to hunting he and his human descendants have wrought ruthless havoc among the lower animals, and at the present day man not only hunts them, but breeds them for the express purpose of destroying them, chiefly for food, partly for amusement Many a person of gentle nature would be amazed and horrified were he at the end of a long life to see *en masse* the hecatombs of living things done to death on his behoof

I have already alluded to two sharply contrasted aspects of the carnivorous nature It is a fact calling for special note that in spite of the intense ferocity of the carnivora their emotional nature has its softer side The most ferocious carnivorous mother lavishes upon her young a devotion not always to be found in the human mother A vixen will wear herself to skin and bone in the nightly hunt for her cubs, and returning to them "red in tooth and claw" immediately fall into a purring mood Her victims excite in her the ferocity to shatter and destroy, her young, the tenderness to shelter and protect To the one she is the embodiment of terror and destruction, to the other of gentleness and protection These facts are pregnant with meaning for us They remind us that the emotional nature of carnivorous man also is compounded of extremes He, too, has his ferocious and his tender side. The ferocious element in him is the source, as we have seen, of some of his ugliest traits such as cruelty and revenge, while ultimately it stands for the crude egoistic principle that "might is right" The tender element on the other hand, is the fountain of all his virtues The great lesson to be learnt from a consideration of this duplex emotional nature, this taint of the devil this touch of the divine is that either side may be cultivated at the expense of the other, the average person may, according as he has been nurtured, develop into an unmanageable hooligan, fearing neither God nor man, or into an entirely respectable, law abiding citizen

The differing attitude towards one another of the carnivorous mother, her prey, and her cubs, is further instructive in that it affords an example of the strong sympathies and antipathies which are displayed by animals, not only between members of different species, but even between those of the same species and more especially of the same sex Much might be written on this interesting subject It must suffice here to draw attention to the decisive influence of personal likes and dislikes in the conduct of human affairs Dislikes, often amounting to virulent hatred, operate antisocially, conducing as they do, not to peace and goodwill, but to bickerings and bloodshed

When we read of the terrible happenings in the present war we begin to wonder how far civilised man differs in his essential nature from early man in his most savage state. Though man's moral nature has doubtless undergone development since primitive times, he still retains much of the wild beast within him We are apt to forget how very much the individual is, both intellectually and morally, the product of his environment What would the modern civilised man be, intellectually considered, were he not, as regards his knowledge, the heir of all the ages? A modern European child brought up under the same conditions as palæolithic man would probably achieve no more in the intellectual sphere than did he We too readily forget that a man's intellectual powers remain merely potential in the absence of the conditions needful to call them forth This explains how it was that during the long palæolithic age man made little or no advance in knowledge, while during the last century he has more inventions to his credit than during his whole previous career

Applying the same principle to man's moral nature, we shall the better understand how greatly that also is influenced by his upbringing While the innate moral leanings of civilised man are doubtless superior to those of the savage, yet it can hardly be denied—so great is the influence of nurture—that an average European brought up among savages would take quite naturally to their most revolting customs, and, on the other hand, that an average "savage" reared in a European community would make a very respectable and peace-loving citizen Let us, then, ever remember that man, like the tiger, has two strongly contrasted dispositions—the combative destructive, and the tender altruistic—at the same time not forgetting that each of these dispositions is, within due limits, an essential attribute of the normal man The man who has no kind of fight in him, who is prepared to take any affront lying down, who is incapable of being stirred to righteous anger, is but half a man, and one wholly devoid of altruistic feeling is equally abnormal. I say that each of these dispositions is needful within due limits The qualification is necessary, for either may be developed to a harmful degree The combative element may be developed to the point of destructive criminality, the tender altruistic feelings may acquire such intensity as to render life intolerable—the hyper altruist may be undone by the defects of his virtues What, however, I desire to drive home is the fact that, taking any average individual, whether he shall be an outlaw or a decent law abiding citizen will depend entirely upon which of the two sides of his nature shall be nurtured. Nevertheless, and in spite of all this, the most careful upbringing is powerless to change man's normal nature to its very depth, to eradicate all potentiality towards the primitive savage Often the effect of education is but to cover with a thin veneer of moral polish the savage beneath That the primitive passions do but slumber in the civilised man is shown not only by the savage orgies which are wont to occur in wars, revolutions and outbreaks of mob violence, and by the murderous activities of the apache, but even more perhaps by the calculated, cold blooded cruelties of the Middle Ages, as displayed, e g by the agents of the Inquisition and in the devilish treatment meted out to prisoners Let no man suppose that human nature undergoes any essential alteration in the course of a few generations What civilised man was in the Middle Ages such is he in his essential nature to-day It is therefore wisest to regard the young human as compounded of the same two opposite dispositions as are found in the tiger, and as being in large measure a wild untamed creature, needing to be broken in and put through a painstaking training from earliest years if he is to be fitted for the difficult duties of good citizenship

It is not of course possible by education to force everybody into exactly the same mould Individual traits, good, bad, and indifferent will show themselves under any system of moral training Taking any number of persons we may arrange them in a series according to their innate moral proclivities, beginning with the moral idiot, whom no education can greatly better and ending with the moral genius who, with very little guidance, blossoms into the saint Numerous individual differences of character will be met with in such a series, many of which are only discernible and understood by intimate acquaintances, if, indeed, by them Many a potential murderer, many a man capable of carrying out the infamies of the Inquisition, passes in society as a right good fellow and is received as a welcome guest, while many a man of kindly nature is judged harshly simply because he does not wear his heart upon his sleeve

The Influence of Man's Hunting Career and of Tribal Life on the Evolution of the Fighting Instinct

Let us now inquire how it has come about that man has acquired his slaughtering propensities The fact, as fact I believe it to be, that it was the search after animal food which caused our ape-ancestor to abandon the forest, suggests that he already had a good deal of fight in him, as well as enterprise, when he entered upon his hunting career and came to compete with the carnivora for animal food The period which elapsed between the abandonment of an arboreal life and the attainment of human hood, say, when tribal life was fully established, was one in which the evolving man steadily increased in skill as a hunter and in which his combativeness underwent steady evolution, for success in the hunt demanded not only skill and cunning, but courage and the combative instinct

Incidentally I may here reitérate my conviction, already advanced in this journal,[1] that it was the conditions entailed by a hunting career which brought about the evolution of the pre human ape into man. For observe the curious situation—assuredly one of the most eventful and dramatic in the whole of man's evolution—when this creature took to hunting Here was a being lacking the stereo typed equipment for slaughter instinctive and anatomical, of the carnivora but gifted with an intelligence surpassing that of any other creature, and endowed with *prehensile hands capable of giving effect to that intelligence* It was a situation in which intelligence counted in the life struggle as it had never counted before, and it inevitably led to the evolution of a higher type This agile, intelligent hand endowed precursor of man was compelled to rely upon his intelligence in hunting his prey, for blind instinct he had to substitute strategy, for natural weapons, weapons made by hand Once the pre human ape started on his career of intelligent, as against instinctive, hunter, he began a struggle in which it was inevitable that a higher and ever higher grade of intelligence should continue to evolve by natural selection until sufficient mental capacity had been attained to render its possessor supreme in the chase

When tribal life with its attendant inter tribal warfare was established—a warfare in large measure at least for the possession of hunting grounds and districts rich in valuable vegetable foods—the evolution of the fighting instinct received a further stimulus for the more courageous and warlike tribes tended to wipe out the less courageous and more peaceful

Here it is necessary to point out that from the evolutional standpoint inter tribal and modern warfare present a striking contrast In the former not only do all or practically all, the men of the tribe take part in the fight but the percentage loss of the vanquished is generally much greater than that of the conquerors Defeat may indeed mean the partial annihilation of the vanquished if not after a single battle, at any rate after a process of guerilla warfare waged it may be through years Thus the effect of inter tribal warfare has been to further the evolution of the bravest and in even greater degree (I may here add) of the most intelligent, tribes But while as I have elsewhere insisted,[2] inter tribal warfare has furthered man's psychic evolution civilised warfare is eugenically hurtful—for whereas individual tribes can annihilate one another, this is not possible with modern civilised nations When two such nations engage one another in war the percentage mortality for each entire nation is much the same and has little or no ultimate effect upon the proportionate population of each nation The effect of warfare between modern civilised nations cannot therefore lead to the survival of a superior nation at the expense of an inferior one Its effect is rather to work against evolution by causing the elimination of the best physical types (the First Napoleon is said to have taken two inches off the stature of the French nation) and of those who display the most courage and daring Were civilised warfare carried on by voluntary armies alone the effect would be to cause a disastrous elimination of the bravest, I say disastrous, for assuredly courage is one of the noblest attributes of man Even with compulsory service a large proportion of the least brave manage to avoid the danger zone

With the establishment of inter tribal warfare the fighting became the most terrible the world had yet known No longer prompted by blind instinct and carried on with nature's weapons (teeth, claws, horns, and the like), in which victory was generally to the physically *strongest* it became a fight with hand-made weapons, wielded warily and with deliberation a fight in which not only *courage* but intelligence played a part such as it had never played before, for it was intelligence which fashioned the weapons and directed their use and which planned the organised attack.

The chief factors in the evolution of the fighting instinct in man have been the reproductive instinct, the search after animal food, and inter tribal warfare The ultimate effect of these factors has been to make man of all vertebrates the most inveterate fighter Not only does he wage incessant warfare on other species, destroying infinitely more than any other vertebrate, but he also fights persistently with members of his own Except in the struggle of rival males for the possession of the female there is comparatively little intra-speciem fighting among the vertebrates whether gregarious or otherwise, members of the same species live together in a comparative harmony Man, on the other hand, from the dawn of the tribal period up to the present time, has made incessant warfare upon his fellows

When we come to compare warfare as waged between civilised nations with primitive inter tribal warfare we find that far from its terrors being mitigated they are becoming greater than ever Human ingenuity has so exhausted itself in the endeavour to devise the most deadly methods of destruction that it is difficult to imagine anything more terrible than those employed in the present war It is true that modern warfare has at various epochs been robbed of some of its terrors by the spirit of chivalry, though it must be confessed that, much as we may commend that spirit, there is something incongruous in two armies setting about to kill one another in a gentleman like way, with *perfect* willingness to be good friends after vast numbers of their comrades have been mutilated and slaughtered But even among the most chivalrous foes some degree of devilry and frightfulness is apt to creep in, and if the spirit of chivalry is lacking on the one or other side then, indeed, is man seen at his worst, as one compared with whom the famished tiger maddened with blood lust is as an innocent babe

(To be conc uded)

URBAN VITAL STATISTICS

(Week ended Sept 8th 1917)

English and Welsh Towns —In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 17 000 000 persons the annual rate of mortality was 11 2, against 10·6 per 1000 in each of the two preceding weeks In London with a population exceeding 4 000 000 persons the death rate was 11·9 or 1 3 per 1000 above that recorded in the previous week among the remaining towns the death rates ranged from 3·6 in Gillingham 4·5 in Eastbourne and 5·6 in Wimbledon to 17 1 in Middlesbrough 16 7 in Aberdare and 18·9 in Gateshead The principal epidemic diseases caused 427 deaths, which corresponded to an annual rate of 1 3 per 1000 and comprised 320 from infantile diarrhœa, 35 from whooping-cough 31 from measles 29 from diphtheria, 10 from enteric fever and 2 from scarlet fever The deaths from diarrhœa, which had steadily increased from 53 to 312 in the seven preceding weeks, further rose to 320 and included 90 in London 23 in Liverpool 14 in Manchester and 12 each in Salford Leeds, Sheffield and Hull The 652 cases of scarlet fever and the 1041 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were respectively 30 and 19 above the numbers remaining at the end of the previous week. Of the deaths in the 96 towns 133 resulted from violence The causes of 24 deaths were uncertified of which 4 were registered in Liverpool and 3 in London

Scotch Towns —In the 16 largest Scotch towns with an aggregate population estimated at nearly 2,500,000 persons the annual death rate was 12·6 against 10 3 and 11·2 per 1000 in the two preceding weeks The 279 deaths in Glasgow corresponded to an annual rate of 13·0 per 1000, and included 16 from infantile diarrhœa 13 from whooping cough 4 from measles and 2 each from scarlet fever and diphtheria The 73 deaths in Edinburgh were equal to an annual rate of 11·5 per 1000 and included a fatal case of whooping-cough and another of infantile diarrhœa.

Irish Towns —The 137 deaths in Dublin corresponded to an annual rate of 17·9 or 3 7 per 1000 above that recorded in the previous week and included 21 from infantile diarrhœa and 2 from whooping cough The 100 deaths in Belfast were equal to an annual rate of 13 3 per 1000 and included 8 from infantile diarrhœa, 4 from whooping cough and 1 from enteric fever

THE PHYSIOLOGICAL AND ANTISEPTIC ACTION OF FLAVINE

To the Editor of THE LANCET

SIR,—The above title appearing over an article by Mr Alexander Fleming in your issue of Sept 1st *is obviously* a misnomer, and one wonders why it was not frankly headed "A Warning Against the Use of Flavine", for in it there are gathered together such assertions and implications as would seem best suited to deter *anyone from testing* the therapeutic properties of flavine antiseptics Unfortunately for Mr Fleming, his experimental facts relevant to the local use of an antiseptic, in so far as they were not contained in our original article,[1] had *practically all appeared* in a second communication,[2] which was published six weeks before Mr Fleming's To take up all his dialectic points would be a waste of time and space, but the more glaring will be referred to Early in the article he states, "This *antiseptic has been* introduced into practice purely as the result of laboratory experiments" What does Mr Fleming mean by this statement? *It can convey only one of two meanings*—either that Mr Fleming would prefer an *antiseptic to be* introduced without any such preliminary test—as he presumably earns his living by laboratory work it may be assumed that this is not *his intention*—or, secondly, it *must signify* that by publishing our original paper we embarked on a warm recommendation of the substance for practical trial at a time when we had no other evidence in its favour than the results of laboratory tests That this was not *the case is proved* by parts of our original paper of which Mr Fleming takes no notice Thus the favourable opinions of the three independent sets of investigators, who had already carried out most *extensive preliminary clinical trials, are quoted*, two of these have also been published separately

To come now to Mr Fleming's experiments First, those concerning the action of flavine on human blood He states *that it agglutinates red blood corpuscles* (a fact to which we drew attention in our original paper when touching on the question of the toxicity of flavine administered intravenously), but he does not add whether he tested *this effect on red* cells *suspended* in *serum* or in saline—a most important point, and one without which the appearance of precision lent by his numerical values is purely fictitious Then flavine is stated *to delay* the coagulation of the blood, apparently this should suit the school of which Mr Fleming is a cadet, for he writes, "Sir Almroth Wright has for many years combined with his hypertonic salt solution some citrate of soda *to prevent clotting* of the lymph in a wound and flavine may be beneficial in this way", but he hastens to add "this action of flavine, however, must be borne in mind when it is applied to freshly incised wounds" Can this mean that Mr Fleming dares to doubt his master in regard to the use of anti coagulants, but that he feels himself at liberty to express his views in the case of flavine, although not when citrate and salt are *under* discussion? *It is worth noting* here that a surgeon of great experience has recently recorded his commendation of flavine precisely because of its property of causing coagulated lymph to appear in wounds In any case, those who have *so* far had no personal experience of flavine can be well assured that the half veiled suggestion of its tending specially to the production of hæmorrhage in *wounds* possesses *no basis of fact* As regards the action of flavine on leucocytes, we have also anticipated Mr Fleming in an investigation on the effects of prolonged contact, and the gist of our observations has been that *even* such leucocytes as have remained for a considerable time (two hours) in contact with a concentration of flavine, which is much more than sufficient *to inhibit growth* of organisms, are yet *able* to exert phagocytic action On the other hand, concentrations of mercuric chloride, which were more harmful to the leucocytes than flavine, lacked all inhibitory action on the bacteria This property of *inhibiting* bacterial growth, which is exhibited by the flavine *antiseptics* up to very high dilutions, appears to us to be of the greatest importance *from the therapeutic* standpoint, since it affords the possibility, especially in recent wounds, of holding the organisms in check while enabling the *natural defensive* mechanisms of the body to come into operation at the same time Mr *Fleming, however, seems* to have no use for such a conception, an antiseptic must kill every organism or it possesses no value for him

His *long contact experiments* with leucocytes which have been rendered moribund through being kept *in vitro* need not detain one Mr Fleming has accused us of having "apparently paid no attention to the time factor" in arriving *at a figure which we used—viz, the* "therapeutic coefficient," or ratio between the concentration of antiseptic which interfered with phagocytosis, and that which killed organisms suspended in serum (We are dealing here with the actual definition which *we gave and not with that which*, for the purposes of his argument, Mr Fleming assumes that we used) There is little point in his contention unless Mr Fleming can show that the majority of efficient phagocytes—i e, those which are capable both of phagocytosing bacteria and then subsequently of destroying them—after having made their diet fail to return *to the tissues*, but sit down on the free surface of the wound until digestion *is complete*, *Colonel* Bond's observations hardly suggest such a view, although no one is very well informed on the matter The really important *fact, however, is that in the case of* the flavine antiseptics there exists such a wide range between the weakest concentration which will suffice to inhibit and eventually to kill organisms in a serous medium on the one hand, and on the other, the great strength which is required to paralyse phagocytosis, hence antiseptic action and the natural defensive processes can be expected to go on side by side No other antiseptic which has been tested affords *results* which justify the belief that with it such will occur to anything approaching the same extent Experiments on the antiseptic action of flavine in blood and pus were described in our first paper, and Mr Fleming's work *adds nothing* new beyond revealing further his inability to grasp the conception that restriction of bacterial activity by means of a chemical agency would represent a valuable therapeutic achievement The same remark applies to the observation, which we have already recorded in our second paper, that a great increase in the number of organisms necessitates a somewhat higher *concentration* of antiseptic in order to effect sterilisation, the degree of this increase was well seen in one of our experiments in which a 20,000 fold increase of bacteria necessitated only about a 2⅓ *fold* increase in strength of *antiseptic! As regards* intravenous injection of acriflavine we have made numerous observations on similar lines to Mr Fleming's but are we to be blamed for not having published them forthwith, seeing that *we have never recommended the use of flavine in order to produce antiseptic action at a distance from the site of introduction of the substance* We did mention that 300 c c of a 1 1000 solution intravenously had produced no ill effect in an adult, but this statement was judged necessary in order that no suspicion might arise as to the possibility of toxic effects following absorption of the substance, which might well *occur in a wound* The *possibility* of conferring antiseptic properties on the urine is an important problem which has already engaged our attention, Mr Fleming's *negative* results demonstrate only that he *seems* to have little conception of the necessity of adjustment of the reaction and other factors in order to secure optimum conditions *In* other words here, as elsewhere, Mr Fleming's *sole* aim *appears to be an attempt to discredit* our work, and to deter those who might be inclined to test the value of flavine by asserting that it has no possible value The unique *property* of being intensified in its *antiseptic* effect by serum seems to be *so* commonplace and contemptible a fact in the mind of Mr Fleming that he passes it by almost without comment Again, the injection of flavine locally into tissues has always been *recommended* with a view to obtaining *contact* between antiseptic and organisms, it has never been suggested that that portion of the dye which had been bound *by the* muscle fibres was *likely* to exercise antiseptic effects Mr Fleming's minced meat experiment is a very old one, as is well known minced tissue absorbs all sorts of substances, *including* the normal protective constituents of the body fluids—i e, complement, *opsonin*, &c, but as comparatively little of a wound surface is likely to be left by the surgeon in a state of

[2] Browning Gulbransen and *Thornton* *Ibid*, July 21st 1917

‘ mincemeat" the experiment does not appear strikingly apposite It appeared to be a hard enough task to demand of an antiseptic that it should not be "quenched" in a serous medium, but now that it has been shown that flavine fulfils this condition, the critic at once complains that it will not act in the presence of excess of mincemeat—this is, indeed an "offensive defensive" on the part of the critic !

The "therapeutic coefficient" already mentioned claims much of Mr Fleming's attention, perhaps the term is to him unpleasantly reminiscent of the ill fated "opsonic index." He says "In regard to flavine, this coefficient, as arrived at by the authors of the expression, gives information so misleading that as a practical test it is quite valueless" Now let it be noted exactly what information we did profess to derive from this coefficient ("TC"), in our first communication we stated "if we find an antiseptic which possesses a high TC value and which at the same time is powerfully bactericidal in the presence of serum, then we know that, as compared with another compound yielding a low TC value, the former substance can be employed in a much higher concentration *qua* bactericidal (and, we might have added, *antiseptic*) efficiency without at the same time damaging the natural defensive mechanism of phagocytosis" One sentence later, in order to place TC in its proper perspective—from which, however, Mr Fleming has no compunction in wresting it—we continued "It must be recognised, however, that the susceptibility of different tissues toward any chemical compound may vary greatly ., we considered that a further valuable indication would be afforded by the behaviour of a delicate epithelial membrane, such as the conjunctiva, towards different dilutions of the antiseptics" In effect we subjected a number of antiseptics to a certain series of tests, then, regarding all the results, we attempted to form a conception of the average of properties In some of these tests, such as the estimation of bactericidal potency and the influence of serum on the latter, known antiseptics, such as phenol and mercuric chloride, yielded results so completely in accord with those of other observers as to afford conviction that our methods were sound, we had also discovered that the flavine antiseptics were distinguished from the rest by outstanding features When on being tested clinically by several independent investigators they were found to be capable of highly successful therapeutic application, then, and not till then, did we conclude that the distinctive behaviour of the flavine compounds in laboratory tests was worthy of publication from a practical point of view, and we added the statement that ‘ the recommendation of this substance for clinical use based on the results of the laboratory tests, has appeared well justified" Mr Fleming has had the substance in his hands (it may be remarked that he obtained his original sample from me personally, although the first evidence of his opinion of it reached me from your pages !) and he has concluded that "the theoretical basis for the use of flavine is thoroughly unsound, and there seems nothing to specially recommend this substance as an antiseptic for use in septic wounds ’ In other words, any surgeon who wishes to employ an antiseptic in wound treatment, and who resorts to Mr Fleming as a scientific tipster, in order to be informed how the backing goes will be told that flavine does not have one point in its favour It is likely that the surgeon will desire to know what has been Mr Fleming's skill in the matter of forecasting previous "events" and he will learn that Mr Fleming's strongest tips in the past have been *the opsonic index as a guide to diagnosis and treatment*, and *Fleming's modification of the Wassermann reaction*—surely two of the most sorrowful "wrong 'uns' that there ever were Mr Fleming's fear of arousing further enthusiasm in matters of scientific medicine can well be understood, but he ought really in the first instance to set right his own tangled accounts before seeking to reform others

I am Sir, yours faithfully, C H BROWNING

PSYCHIATRY IN ENGLAND

To the Editor of THE LANCET

SIR,—Dr Weatherly in his letter in your issue of Sept 8th states that ‘the recovery rate of insanity is no higher to-day (in asylums) than it was in the decade 1865 to 1675 Perhaps Dr Weatherly will excuse my saying that this conclusion is of little value if it has been inferred from a recovery rate calculated on the total number of admissions irrespective of the ages of those admitted, as the recovery rates of all asylums are now adversely affected by the increased number of senile cases admitted.

Surely there must be few, if any, asylums in which "the want of proper departmentisation of cases" occurs, it is an essential feature of the new segregate type of institution, and in many years' asylum experience I have never seen patients with a suicidal tendency placed "on the side of the asylum with the worst cases" unless those particular patients exhibited other symptoms that made them manifestly unsuitable companions for the ordinary type of suicidal case

With regard to the treatment of functional mental disturbances there are functional cases *and* functional cases, and relative to many there is a world of wisdom in the following aphorism of the late Sir Thomas Clouston "What is good is not always pleasant in moral as well as in medical treatment"—I am, Sir, yours faithfully,

H DE M ALEXANDER

Aberdeen City Mental Hospital Sept 10th 1917

TREATMENT OF THE INVALIDED SAILOR OR SOLDIER

To the Editor of THE LANCET

SIR,—May I be allowed to point out an omission in the article on the above in THE LANCET of Sept 8th, p 404 The full statement is, ‘ Payment being made at the dividend rate found to be payable on that scale out of the Central Medical Benefit Fund for the year" (Memorandum 233/I C, par 7, lines 7 8 and 9) The very same words are used in Memorandum 234/I C, "For Issue to Doctors," par 5, lines 7 8, and 9 The *dividend* rate is only 90 to 92 per cent of the scale, and the Memorandum means that the Treasury will bring up any deficit to this dividend rate and not to the full remuneration quoted in THE LANCET—viz, visit 2*s*, &c I have reason to believe that means may be taken to prevent over visiting

Is it necessary to say that the rate of remuneration quoted is too low for the increased and increasing cost of living and carrying on of practice ?—I am, Sir, yours faithfully,

JAMES GARDNER,
Chairman of the Burnley Panel Committee

Burnley, Sept 9th 1917

ORIGINALITY AND ENTERPRISE

To the Editor of THE LANCET

SIR,—The article entitled as above in your issue of to-day is incorrect when it is stated that the Chemical Society is the only British body which publishes an abstract journal "Physiological Abstracts’ which is published by H. K Lewis and Co for the Physiological Society, is now in the second year of its existence, and constitutes what I conceive to be a praiseworthy effort to accomplish what the writer of your article desires Although it does not deal with the immense mass of available clinical literature, it nevertheless interprets the word physiology in a wide sense, and includes an international survey of physiology and allied sciences from the academic point of view, and also, to use a good old phrase, as the Institutes of Medicine. I am asking the publishers to forward you a copy of its latest issue You were good enough to write a friendly notice of this new journal when it first appeared Perhaps you will be able to see your way to glance through the one I send so that you may be able to corroborate what I say regarding its merits or otherwise It is regrettable that the facts were not ascertained before the lack of British enterprise was lamented

I am, Sir, yours faithfully,

W D HALLIBURTON,
Editor of "Physiological Abstracts"

King's College London Sept. 8th 1917

⁂ We were perfectly aware of the facts We have received and reviewed "Physiological Abstracts," and again recommend this serial work cordially to our readers But we were considering in our article the publication of abstracts dealing with medicine generally, as the papers in the *Journal of the Chemical Society* deal with chemistry generally It may be that this is too high an ideal, and that we must rely on the separate branches of medical science for systematised reports on their individual work. In such a category ‘ Physiological Abstracts" would enjoy a high place —ED L

The War.

The Casualty List

The following names of medical officers appear among the casualties announced since our last issue —

Died of Wounds

Capt J H Bampton, R A.M C, attached Royal Field Artillery, was educated at Birmingham University and at Berne, and qualified in 1911 He held the appointment of house surgeon at the Birmingham General Hospital, and prior to joining up was in practice at Gravelly Hill, and was assistant school medical officer for Birmingham

Wounded

Capt L Ball, R A M C, attached Royal Berks Regiment

Capt W Stobie, R A.M C, attached Oxford and Bucks Light Infantry

Capt A J V Mathews, R A.M C

Capt W H Cornelius, R A.M C, attached Worcester Regt

Capt A. W Matthew R A M C

Capt J A Smith, R A M C, attached Gordon Highlanders

Capt H G Janion, M C, R A M C, attached Royal Horse Artillery

Capt J C Sale, M C, R A.M C

Missing

Lieut Col G S Williamson, R A M C

Casualties among the Sons of Medical Men

The following additional casualties among the sons of medical men are reported —

Major G B C Irvine, 9th Bhopal Infantry, India Army died of wounds, eldest son of the late Surg Gen G J Irvine, R N

Private J H Yelf, Canadian Infantry, killed in action, youngest son of the late Dr L K Yelf, of Moreton in Marsh, Gloucestershire

A J E Warburton, London Regiment, died of pneumonia, son of the late Dr A Warburton, of East Molesey

Major J H Ratton, Royal Garrison Artillery, killed in action, eldest son of Lieut Col J J L Ratton, late I M S, of Blackheath, S E

Private D M Jacob, Canadian Expeditionary Force, killed in action, youngest son of the late Dr A. H Jacob, of Dublin

Lieut G E Story, Royal Engineers, died in hospital, son of the late J Story, M.R C S, &c, of Westbourne Terrace road, London

Second Lieut J A Humphreys, Royal Field Artillery killed in action, youngest son of Lieut Col C E Humphreys, R.A M C, J P, county medical officer for Montgomeryshire

Second Lieut T S Hinnell, Suffolk Regt, killed in action, eldest son of Dr J S Hinnell, Bury St Edmunds

Lieut R F Lawrenson, Cheshire Regt, died of wounds, only son of Dr H F Lawrenson, of Muswell Hill, London

The Honours List

Victoria Cross

The much coveted distinction of the Victoria Cross has been conferred upon the following member of the medical profession who is, alas, no longer with us —

Temp Capt Harold Ackroyd, M C, late R A M C (attached Royal Berks Regiment)

For most conspicuous bravery During recent operations Captain Ackroyd displayed the greatest gallantry and devotion to duty Utterly regardless of danger he worked continuously for many hours up and down and in front of the line tending the wounded and saving the lives of officers and men In so doing he had to move across the open under heavy machine-gun rifle and shell fire He carried a wounded officer to a place of safety under very heavy fire. On another occasion he went some way in front of our advanced line and brought in a wounded man under continuous sniping and machine-gun fire His heroism was the means of saving many lives and provided a magnificent example of courage cheerfulness and determination to the fighting men in whose midst he was carrying out his splendid work This gallant officer has since been killed in action

(The announcement of the death of Captain Ackroyd who was a student at Guy s Hospital and practised at Royston Herts was made in The Lancet of August 25th, 1917 p 331)

"Our Day," 1917

An urgent charitable appeal for aid is being made on behalf of the Joint War Committee of the British Red Cross Society and the Order of St John. The danger is that "Our Day," fixed for Oct 18th may suffer if helpers in their thousands do not come forward Women in all parts of the kingdom who have sacrificed their leisure in former years are now giving their whole time to some phase of war work Their places must be filled Organising committees have vacancies, there is urgent need for sellers of "Our Day" emblems, and suggestions for any method of raising funds, by concerts, social gatherings or sports, in particular localities will be gladly welcomed The needs of the Red Cross work were never greater, and they are increasing every day "Our Day" is everybody's opportunity to contribute to the comfort, care, and well being of the Empire's wounded and stricken heroes Already the self governing Dominions, Crown Colonies, and Protectorates have thrown themselves heartily into the movement, which has the best wishes of the King and Queen and Queen Alexandra Red Cross activities at the present moment are costing more than £5 every minute The money is spent in minimising suffering—surely the noblest aim a people can be invited to associate themselves with, especially when it is their own kith and kin who are benefiting To buy and wear a Red Cross emblem on Oct. 18th will be the outward sign of sympathy To do something in the intervening weeks will be really practical support. Miss C May Beeman, the organising secretary, will welcome any offers of assistance addressed to 10 West Bolton Gardens, London, S W 5

The Medical Examination of Aviators —In October of last year the Army Medical Service appointed a special medical board for the examination and selection of flying officers This board was composed partly of army doctors and partly of civilian experts and has been working continuously since it was formed Each candidate is examined by three different doctors, and their reports are then assessed by one or two other doctors, the candidate being again examined if necessary Various tests have been employed, Bárány s amongst others, but experience has shown that it is not advisable to lay too much stress on any one test as a cause for acceptance or rejection The details of the medical examination for flying officers in this country have been formulated after a year's experience, and will be submitted in due course to the Air Board

It is not to be assumed that finality has yet been reached as to the medical examination and *testing of* candidates for flying work. This subject requires a more thorough knowledge of the disabilities which affect flying men than we possess at present It is hoped that further progress will be made in this direction by the study of these disabilities in a special hospital for flying officers which will soon be available. When the type of man who has broken down and the various disabilities which develop in air work have been more thoroughly studied, the selection of the best type of candidate will be carried out with more knowledge and precision than is possible at present

2nd Eastern General Hospital, Brighton —As one of the many adjuncts of the 2nd Eastern General Hospital at Brighton there was opened on August 29th the East Hove Schools, which will be used solely by convalescents, or walking cases, the object being as far as possible to relieve the mother hospital near by for the reception of severe surgical cases Accommodation has been provided for 165 beds and 155 of these were occupied at the little informal opening ceremony There is no operating theatre but there is a finely equipped dressing room The school swimming bath is not to be used at present.

The Employment of American Practitioners in Military Hospitals —In certain Commands it has been decided to supersede the British civilian practitioners at present acting as the staff by American medical men. In this way more British practitioners will be available to meet the pressing home needs which have been made clear by the work of the Central Medical War Committee

OBITUARY OF THE WAR

JOHN BROMLEY RAWLINS, M B, B S Lond,

CAPTAIN ROYAL ARMY MEDICAL CORPS

Captain J B Rawlins, who was killed in action in France on August 16th at the age of 27, was the elder surviving son of the late John Rawlins, of Erdington, Birmingham, and Mrs Tom Green, of Warren Drive New Brighton. On leaving Bromsgrove School he studied medicine at St. Mary's Hospital, London, graduating M B, B S in 1914 Shortly after the outbreak of war he was granted a commission in the Royal Army Medical Corps (Territorial Force) and was attached to the staff of the 3rd London General Hospital, Wandsworth In the autumn of 1915 he went to France, where he saw continuous service up to the time of his death, which was caused by the bursting of a high-explosive shell in a dressing station His commanding officer writes of him as a charming comrade and a hard working and capable officer

Captain Rawlins was engaged to be married to Sybil, only daughter of Dr Oliver Withers, of Sidmouth, Devon

CHARLES ALFRED WHITING POPE M A., M B Camb.,

CAPTAIN ROYAL ARMY MEDICAL CORPS

Captain C A. W Pope, who was officially reported "Missing, believed drowned' on the occasion of the torpedoing of the transport *Transylvania*, on May 4th, was in his fortieth year and fourth of the ten sons, originally serving of Alfred Pope, F S A. J P, of Wrackleford, Dorchester He received his education at Twyford School and Charterhouse whence he proceeded to Trinity College, Cambridge, graduating in honours in 1902. He obtained his medical degrees from St. Bartholomew's Hospital a year later, and after serving as house surgeon to the Devon and Cornwall Hospital Plymouth, went to South Africa as resident to the Somerset Hospital, Cape Town Returning to England in 1907 he practised in partnership at Rugby, and subsequently in Hastings and St. Leonards On the outbreak of the war he offered himself for active service and obtained a commission in the Royal Army Medical Corps After two years' service first at Seaford as medical officer to the 7th South Wales Borderers and then in Aldershot, he was ordered to Egypt in April 1917 and it was whilst he was on his way to take up this appointment that he lost his life When the boat was struck he was in the ship's hospital and after seeing that the patients were safe he went to the parade deck Shortly afterwards he heard that several had been wounded down below by the explosion and Captain Pope went with a party to rescue them Whilst dressing their wounds he went down with the ship The facts are stated by two of his companions one of whom was working with him up to a few minutes before the vessel sank.

Captain Pope married in 1909 Marion Ruth eldest daughter of the late Captain J J A Gravener R N, of Avenue House Dorchester His widow with two sons and a daughter survive him

BENTLEY MOORE HUNTER, M.B, Ch B Glasg

CAPTAIN ROYAL ARMY MEDICAL CORPS

Captain B M Hunter, who was killed in action on July 31st, aged 29 years, was the fifth son of Charles Hunter, B A., of Drochduil Public School, Dunragit, N B Before leaving the Public Elementary School he gained three bursaries, and afterwards attended the High School Stranraer, for three years Here he early showed a predilection for the science side of the instruction and on leaving joined the medical classes at Glasgow University He was a student of some distinction, prizeman and medallist, and graduated before being of age to practise On attaining the age of 21 he acted as assistant at Consett, Durham for three years, and later to Dr R. Wallace, of Saltcoats, Ayrshire, with whom he continued until he joined the Royal Army Medical Corps in May, 1915 His first year in the Royal Army Medical Corps was passed in Lemnos and Egypt and during the rest of his service he was attached to a regiment which has taken part in several of the most strenuous engagements He had just finished dressing a wounded man when he was struck himself and died immediately

Captain Hunter's chief writes of him "His attention, agreeable and quiet manner, were greatly appreciated by his patients, and he showed that he was well qualified in his profession He will be greatly missed in this neighbourhood'

HENRY YOUNG CAMERON TAYLOR, M B Edin, F R C S Edin,

CAPTAIN ROYAL ARMY MEDICAL CORPS

Captain H Y C Taylor, who died on August 25th of illness contracted in a military hospital, was third son of the late Alexander Taylor, of Edinburgh He graduated M B, C M Edin in 1896, taking his Fellowship there in 1905 After holding positions as clinical assistant at the Golden square Throat Hospital and the Central London Ophthalmic Hospital he was resident at the Hospital for Sick Children Great Ormond street, and the Huddersfield Infirmary He served as a civil surgeon in the South African Field Force when he contracted enteric fever, but recovered and remained at his post In 1909 he settled at Bexhill on Sea, where he built up a large practice After the outbreak of hostilities he worked under the French Red Cross at Dunkirk for two months joining the Royal Army Medical Corps in April 1915 He was attached for a while to the Hampstead Military Hospital, served on the hospital ship *Britannic* and was then posted to the Royal Victoria Hospital Netley, where he served on the surgical staff up to the time of his illness He was taken suddenly ill with what was at first considered to be influenza, after partial recovery he went home on sick leave passing into a painful condition of septicaemia to which he ultimately succumbed. One who knew him writes of Captain Taylor 'He won the affection of his patients by his invariable kindness and untiring devotion to their welfare while their confidence was

secured by many proofs that he kept himself well informed with modern progress His loss has been keenly felt by a large circle of friends, by none more than the wounded soldiers, to whom he devoted unsparingly the best he had to give Taylor's surgical results were excellent, his handling of the severe septic cases by large incisions and free drainage almost abolished secondary hæmorrhage in his wards at Netley He was a loyal and generous colleague "

Captain Taylor married in 1911 Eothen, eldest daughter of the late Francis E Colenso and grand daughter of the late Bishop Colenso

ANDREW BEACONSFIELD ROSS, M A, M D EDIN,

LIEUTENANT, ROYAL ARMY MEDICAL CORPS

Lieutenant A B Ross, who was killed in action in France on August 6th at the age of 39, was the son of James Ross J P, of Invergordon, Ross shire and was educated at Edderton Public School and at Tain Academy He was a brilliant scholar at Edinburgh University, graduating M A. in 1898, M B, Ch B in 1902, and M D in 1906, gaining the Vans Dunlop scholarship in surgery and physiology and being elected president of the Royal Medical Society After qualifying he held the post of house physician to the Hospital for Sick Children, Great Ormond street, as well as resident posts at the Royal Infirmary, Edinburgh, and the Glasgow Maternity Hospital After a voyage to South America and some experience as assistant in general practice, he went into partnership with Dr J E Judson, of Ashton under Lyne, with whom he was associated for six years

His partner writes of him as a man of exceptional ability, all of whose work was done with a conscientious thoroughness coupled with kindness and sympathy with suffering He will be much missed in Ashton

---

HOSPITAL MAGAZINES—With the autumn number of the *Craigleith Chronicle* (2nd Scottish General Hospital Craigleith, Edinburgh, price 6*d*) this magazine ceases to be a monthly publication, but the organisers hope to continue it as a quarterly, and a Christmas number is promised The current issue includes the story of the capture of Baghdad, from the pen of Captain the Rev Dr W Ewing, M C The illustrations are particularly good An editorial note states that the total number of men admitted to Craigleith and its auxiliaries from the beginning of the war, up to and including July 2nd, 1917, amounts in all to 35,829 Craigleith receiving 30 237 — The *Gazette of the 3rd London General Hospital* (Wandsworth, S W 18 Price 4*d*), which, like the preceding, was among the first of the magazines of this class to be published, maintains a high standard, and the illustrations have considerable merit "Strafe the Flies," by Sergeant H J Gilby, is the title of a popular study of *Musca domestica*, and gives in a familiar manner much sound information regarding the house fly as a disease carrier

Medical News.

THE NATIONAL FOOD REFORM ASSOCIATION —The executive committee of this association in April last passed a resolution welcoming the action of the Ministry of Food in recommending communal kitchens, as making for individual and national economy and a better nourished population" The system has been widely adopted, and the committee claims that it has been generally recognised that it results in saving foodstuffs, fuel, and labour, diminishes waste, and affords opportunity for improving cookery The committee has already been able to assist both public and private promoters of such kitchens in town and country and offers to be of service to local authorities and others Being wishful to secure as complete information as possible, the committee will be glad to receive particulars regarding any central kitchens These should include (1) nature of management—i e local authority, society, or *ad hoc* committee (stating whether wage-earners are represented), (2) scope—i e, whether for children, adults or both, (3) days or hours open, (4) whether any meals are served on the premises, (5) section or sections of the community using same (6) date of opening, (7) average number of meals served daily, (8) approximate population, (9) experience, training and salary of manager and cook, (10) number of staff including volunteers, if any, (11) menus for a fortnight with tariff (12) financial result—i e whether self supporting and, if not, how deficit met (stating if premises are rent free or at a nominal charge), (13) copies of any descriptive leaflets circulated and (14) any general remarks or suggestions based on experience

IN connexion with a child welfare scheme, the Newry urban council have decided, subject to the consent of the Newry board of guardians to open a maternity centre in the dispensary and to pay Dr R Flood £20 for his services in connexion with it

THE LATE MR DAVID CHRISTIE, L R C P EDIN —Mr D Christie who died recently at his residence Carrigart, close to the famous Rosapenna golf links, co Donegal was one of the oldest medical practitioners in Ulster For upwards of half a century he had been medical officer of Carrigart Dispensary District, and was a very well known medical man in co Donegal His early professional life was passed as a surgeon in charge of emigrant sailing ships and he had medical charge of the *Stradacona* and the *Minnehaha* during the years 1865 and 1866, these being the last of the sailing ships on which emigrants embarked for America from the port of Londonderry

A MEDICAL ANTIQUARY —Mr Henry Laver M R C.S L S A consulting surgeon to the Essex and Colchester Hospital who died at his residence Colchester on August 31st aged 87 was a well known antiquary and an authority on architecture and local history For over 50 years he practised medicine in Colchester, taking at the same time an active interest in all that concerned the welfare of the borough in which he lived In 1555 he held the office of mayor He was chairman of the Colne Fishery Board and of the borough and port health committee curator of the Colchester Museum an ex president of the Essex Archæological Society and the author of a work on the mammals of Essex

A RED CROSS CONFERENCE —A meeting is being held at Geneva consisting of delegates of Red Cross Societies of Denmark, Spain, Holland, Norway, and Switzerland, to discuss means for the relief of prisoners of war in the belligerent countries

PRESENTATION TO PROFESSOR HASLAM —Mr W F Haslam, F R C S, professor of surgery in the University of Birmingham and surgeon to the Birmingham General Hospital with which institution he has been connected for 36 years, was presented on Sept 10th, on the occasion of his retirement with an address and his portrait in oils to be hung on the walls of the hospital At the same time Mrs Haslam was presented with a diamond and pearl pendant

HEALTH OF BELFAST —A Belfast correspondent writes — "It is satisfactory to record that between July 22nd and August 18th, as reported to the September meeting of Belfast city council the average annual death rate (11 4) and that from zymotic diseases (0 7) were lower than in the corresponding period of last year, and that the death rate from chest affections was only slightly higher (3 3 instead of 3 2)"

PORTSMOUTH INFECTIOUS DISEASES HOSPITAL —An extension of this hospital was opened on Sept 5th It consists of two pavilions with 63 beds, an observation block operating theatre nurses' home, &c, which have been erected at a cost of £30,000 The observation block contains 20 beds all in single wards, with glass partitions between each ward This enables observation to be kept from a central room, and provides complete isolation of every case so that there is no chance of cross infection There are now 264 beds in the hospital, being one bed per 1000 of the population the provision which the Local Government Board requires

THE ROYAL SANITARY INSTITUTE —At the Town Hall, Chatham on Sept 29th, a meeting of the institute will be held when discussions will take place on Some Points in Epidemic Cerebro-spinal Meningitis, introduced by Surgeon A G L Read, R N V R, assistant medical officer London County Council, on Some Aspects of the Housing Problem, introduced by Mr J Holroyde, medical officer of health for Chatham, and on Public Abattoirs, introduced by Mr R L Honey, the assistant borough surveyor of Chatham The chair will be taken at 10 30 A.M by Lieutenant-Colonel H R Kenwood, R A.M C After luncheon visits will be made to the Royal Naval Hospital, the Army abattoir and bakery, and Rochester Cathedral Further particulars can be obtained from the honorary local secretary Mr J Holroyde, Health Department, Town Hall, Chatham

THE name of Dr John Phillips, consulting obstetric physician to King's College Hospital was inadvertently omitted from the list of the hospital staff in our last Students Number

THE DOMICILIARY SUPPLY OF DRUGS TO THE SICK POOR —Lewisham guardians have been making inquiries as to the method adopted by the various metropolitan unions for supplying drugs to their outdoor sick poor Replies were received from 22 unions and from these it appeared that the district medical officers of Lewisham are the only officers in the metropolis having to provide a surgery and to supply drugs at their own expense The salaries paid to district medical officers vary considerably throughout the metropolis and are governed to a large extent by the number of orders received by the medical officers No reliable statistics are obtainable in respect of any year after 1914 For that year the undermentioned is the rough average payment per order made to the district medical officers of the 22 unions or parishes which had supplied information Camberwell, 2s, Chelsea 5s 3d (some drugs supplied through local chemists) Fulham, 2s 1d Greenwich, 3s 10d, Hammersmith, 2s 10d (in one district (17 orders) £5 per annum allowed for drugs), Hampstead 6s Holborn, 8s 4d, Islington, 2s 5d Lambeth 2s 10d (in five districts drugs are supplied under contract with local chemists), Lewisham, 2s 6d (drugs and surgery provided by medical officers), City of London, 15s 2d Paddington 3s 3d, Poplar, 2s 5d (additional £10 per annum allowed for drugs supplied after dispensary hours) Shoreditch, 2s 6d Southwark 4s 6d, St George in the East, 3s 2d St Marylebone, 3s 11d, Stepney, 3s Wandsworth, 2s 11d (in three districts salaries include cost of drugs), City of Westminster, 6s 8d, Woolwich, 3s 9d (in one district (60 orders) £12 10s per annum allowed for drugs) It is estimated that each order entails an average of four "visits" The Bermondsey and Bethnal Green guardians have adopted the modern method of putting the medical relief of their respective districts under the direction of the infirmary medical superintendent and his assistants and the Lambeth guardians have this system in force in four of their medical relief districts

THE CAUSATION OF SEX

To the Editor of THE LANCET

SIR,—Professor F R Lillie has just published a most interesting paper on "Sex determination and Sex differentiation in Mammals" Proceedings of the National Academy of Sciences U S A. July, 1917, p 470) It deals largely with his researches on the question of the free martin in cattle With your permission I quote two passages "We must regard sex as determined in the usual sense of the word, at the time of union of the gametes The question, however arises whether sex-determination involves an irreversible tendency to the corresponding sex-differentiation, or whether such differentiation is more or less controllable or even completely reversible?" Again at the end of this paper after discussing his own results, Lillie writes "Nor can it be predicted in advance what the result of the inverse experiment might prove to be i e treatment of the male zygote from the beginning of sex-differentiation with female hormones Such experiments will be necessary for the full solution of the stated problem We can, however, state confidently on the basis of the present results that sex determination in mammals is not irreversible predestination, and that with known methods and principles of physiology we can investigate the possible range of reversibility "

I am, Sir, yours faithfully,

London N W., Sept 1st 1917 LEONARD J KIDD

AN EXCELLENT BABY BOOK.

WE have received from the Provincial Board of Health, Parliament Buildings, Toronto, a pamphlet of 54 pages entitled ' The Baby and designed to teach the mother how to care for her infant and keep it well The information is accurate and helpfully expressed and in good taste. A novel laxative for the mother is given as 'Ordinary bran eaten raw with wholesome cream is often extremely beneficial" We congratulate the Ontario Health Board and Dr J W S McCullough its chief officer on what cannot fail to be a useful piece of propaganda against preventible infantile disease and mortality The frontispiece reproduces the group "Motherhood" from the Victoria Memorial London

DOMESTIC MEDICINE AMONG SPIRIT RAPPERS

IT is a question whether the fashionable combination of spiritualism and sheer quackery which prevailed some 50 years ago has ever been paralleled, even in the age of Christian Science Looking over old letters a correspondent has found the following message received in October 1872 by old ladies who at the time were regarded as very cultivated persons They believed it to emanate from the spirit of their grandmother, a somewhat stern Low Church woman a friend of John Wesley Born in 1777, she abandons a century later the notably Johnsonian style of her still existing memoirs and thus expresses herself

'Send my message with loving haste to my suffering child She will be comforted by my words Tell her to take courage She will need much care during the winter but she must not be down hearted Such a very severe attack will leave her very subject to cold She will derive much benefit from *Bryonia* if she will only persevere That with *Aconite* is invaluable Send her a little book like yours dear X and then she will not be frightened The simpler the directions the better No complicated book will be of any use to her Do you understand, dear X.? She might save herself and her children more serious illness by taking indisposition in time by these precious simple remedies Do not delay sending her this relief for her cough *She need have no compunction in taking them unknown to her doctor* Have faith and confidence in these wonderful medicines One drop in a tablespoonful of water every two hours is not bad for her The usual dose is two or three drops in half a wine glass of water at night or morning but should the dose be repeated through the day do not take more than one drop at a time For a cough take *[illegible]* and *Aconite* alternately Tell Jane what a harmless and comforting thing syrup of horehound is for softening the irritation caused by the cough Farewell dear ones

The last touch being orthodox might well emanate from some spirit of old date Horehound was a famous eighteenth century remedy The cold which Jane suffered from was a violent form of influenza which visited Fifeshire in the autumn of 1872 after a long, cold and wet Scotch summer by Dr Bell a then well known [illegible] it was very customary at [illegible] in [illegible] with [illegible] and an effervescing mixture but when sent his patients to bed This particular patient suffered from abscesses in both ears Old letters from which the above notes have been taken, are often full of such quaint accounts of illness and self medication, and even as lately as the latter half of the nineteenth century are often an epitome of superstition, even when written by highly cultivated people

THE SUMMER TIME ACT

THE Home Secretary gives notice that summer time" will cease and normal time will be restored at 3 o'clock (summer time) in the morning of Monday next Sept 17th, when the clock will be put back to 2 A M Thus, the hour 2-3 A M "summer time" will be followed by the hour 2-3 A M "Greenwich time" It was on April 8th 1917, that this year's period of summer time started in this country In the year 1916 it commenced May 20th-21st and ended Sept 30th-Oct 1st In 1917 it has thus started six weeks earlier and will end two weeks earlier than in 1916

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, *and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification*

Letters whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

Local papers containing reports or news paragraphs should be marked and addressed 'To the Sub-Editor"

We cannot undertake to return MSS not used.

Offices 423, STRAND, LONDON W C 2.

A Method OF WOUND TREATMENT

BY THE INTRODUCTION OF LIVING CULTURES OF A SPORE BEARING ANAEROBE OF THE PROTEOLYTIC GROUP

BY ROBERT DONALDSON, M A, M.B, CH B EDIN, F R C S EDIN, D P H,
BACTERIOLOGICAL SPECIALIST WAR HOSPITALS, READING PATHOLOGIST ROYAL BERKS HOSPITAL, ETC

(Report to the Medical Research Committee)

AT the outset of this paper we wish to emphasise the fact that it is strictly of the nature of a preliminary communication, which does not embrace all the work we have done or are doing in this particular line of investigation We furnish however, the principles underlying this form of wound treatment and are conscious that improvements in its method of application or modifications of certain theoretical statements in connexion therewith may later be found necessary

Our excuse, and a valid one we trust, for putting forward the result of our investigations at this stage is the urgency of the situation, and while much of the detail remains to be worked out the method here described can be made use of *now* in the treatment of wound infections The subsidiary questions arising from it are being worked out at leisure, but owing to pressure of routine work the results are not yet ready for incorporation in this paper As however, we believe the main principle to be sound and the need for its recognition and practical application to exist now in an acute form, we venture to hand on the main results we have arrived at so far

METHODS OF WOUND TREATMENT

The problem of the best method of wound treatment after three years of experience in the theatre of war is still unsolved That which will be most conservative of human life and limb which will curtail the convalescence of the wounded man which is easy of application, and at the same time requires least attention will surely be acclaimed the best method of treatment At the outset of war treatment by antiseptics was the general rule, but it was soon recognised that ordinary antiseptic methods of pre war time days were futile in attempting to combat the gross infections of these wounds At this juncture Sir Almroth Wright came forward as the opponent of antiseptic treatment and proposed the so called physiological treatment' by means of hypertonic saline solutions We are not concerned here, however with the question of antiseptics *versus* saline or with any attempt to find fault with the method of treatment recommended by Sir Almroth Wright In our opinion the chief merit of Wright's work lies in the fact that he helped to break the spell which had bound surgeons to antiseptics and called attention to ordinary salt as an alternative method Out of this method another was evolved which in turn has led to the new method which we put forward in this paper Colonel H M W Gray C B basing his theories of treatment on those formulated by Wright introduced in order to promote a so called lymphagogue action and to obviate the need for elaborate drainage or continuous irrigation the method of treatment by salt packs Briefly put the merit of the salt pack lies in the ease with which it can be applied in the fact that it can be left *in situ* for five or six days without requiring renewal with all the advantages this carries with it to the patient and in the fact according to its inventors that it effects more or less closely the changes which Wright insists upon are necessary for the rapid and successful cleansing of a wound from infection Whether or not the salt acts physically as Wright and his followers believe, we do not propose to discuss now, although on the lines of their explanation there is much that requires further elucidation Suffice it to say that according to them the salt acts in the first instance as a lymphagogue, so preventing a wound becoming what Wright calls "lymph bound", that the lymph flow tends to loosen sloughs so that they come away more readily, that later the salt solution of reduced tonicity has a chemio tactic influence on the leucocytes which together with the salt present complete the victory over the invading bacteria

Results of Treatment with Salt Pack

Of all the methods of wound treatment in use, one of us (L J) early became a convert to the salt-pack method, with results which were in the majority of cases all that could be desired, and which coincide with the published results obtained by all those who have given this method of treatment a fair trial The adoption of this method has considerably curtailed the patient's period of convalescence, and has, moreover, succeeded where other methods have failed, including the much advocated Carrel-Dakin procedure

The wounds were generally five or seven days old at least before the patients arrived in Reading, and came with a variety of dressing They were mostly gunshot wounds, and as such practically always involved muscle, parts of which were dead or dying as a result of the trauma. The tissues were generally dirty, sloughy and purulent while the surrounding area was frequently œdematous Where the patient was obviously ill, in pain, and running a temperature, it was marvellous to find that in three days after the salt pack had been introduced the temperature fell to normal and that in a week or ten days' time the wound was a healthy bright red colour and well covered with firm granulations This result was achieved with the minimum of discomfort to the patient, since after the first packing it was unnecessary to redress it for some five, six, or seven days In this way rest, one of the great allies in successful healing, was obtained The fall in temperature, and the mental quietude engendered by the knowledge that no daily dressing was to be looked forward to, contributed to the patient's welfare He was able to obtain refreshing and normal sleep and his appetite generally improved, so that many of the vicious circles in operation were thus broken

Impressed with the results obtained, we were anxious to know exactly whether the bacterial content of wounds so treated was actually less than before the treatment was begun, in other words we desired to know if, apart from the claims of the protagonist of the method as to its physical properties in the wound the salt had any definite and marked bactericidal action either directly on the organisms or indirectly through the leucocytes To this end a series of observations were made before and after the salt pack had been removed with, however, disappointing results The bacterial flora seemed to be as numerous immediately after removal of the salt pack as before it and the pursuit of this investigation was abandoned owing to pressure of other routine work Nevertheless the results *qua* the healing of the wound were excellent and not being able to accept the theories put forward in explanation of its efficacy we still remained in the dark That the wounds did well and got well probably sooner and with less disturbance than by any other method was a clinical fact beyond dispute How it did so we could not tell and this is in accordance with the published statements of all others who employ this line of treatment Men begin tentatively to try the method rapidly become converts to its use, and, while acknowledging its extraordinary effect on wounds profess ignorance as to the principles which underlie it

THE FOUL ODOUR OF SUCCESSFUL CASES ISOLATION OF ANAEROBE

With this problem still unsolved it was noticed that while the majority of cases treated with the salt pack did well and followed a more or less stereotyped course towards complete recovery one or two cases were outstanding exceptions and recourse was had in these to other methods of treatment Why some cases treated in exactly the same way as the others should not improve formed a new problem until a clinical observation—and on this hinges the subsequent work—was made by one of us (L J) This observation is of crucial importance It had been noted by all who came in contact with wounds so treated, as it has been

all who have adopted this method, that a powerful and most offensive odour was emitted from the salt-packed wound Girling Ball,[1] for example, to quote one, says that the "foul odour is not an indication for changing the plug" Others say that the odour is a signal for change of dressing No one attempts an explanation except in one paper[2] we have read where the view is expressed that it is due to a "decomposition in the dressings themselves" It was noted, however, by one of us (L J) in the course of clinical work that one or two of those cases which failed to improve were also devoid of this peculiarly offensive fœtid odour, and on recalling one or two previous cases that had not progressed satisfactorily it was remembered that they too were devoid of odour

On considering together this phenomenon, and its possible explanation, we came to the conclusion that probably in the evil smelling but successful cases there was present a bacterium which was absent from those which did badly and which did not smell The idea was at first conceived that the salt pack might produce physical conditions in the wound which favoured the growth of this bacterium, and that the good results of the treatment might be directly due to its activity Taking everything into consideration, it was thought by one of us (R D) that the organism present was most likely to be an anaerobe, and steps were accordingly taken to determine the presence or absence of such an anaerobe or anaerobes A case was chosen from which the salt pack was about to be removed This case was one which had obviously done well under the treatment and which emitted a most offensive odour From the pus obtained from the wound two anaerobes were isolated in symbiosis one with round terminal spores in very small numbers, and the other a bacillus having a large subterminal oval spore The latter was present in large excess over the round sporing bacillus

The meat-broth tube in which the pus had been cultivated obviously contained a mixture, and as that tube showed evidence of active proteolysis and emitted the same powerful offensive odour as the wounds did, it was felt that the organism present in predominant numbers was responsible

After two attempts, made as already described by one of us (R D) in THE LANCET,[3] the oval sporing bacillus was obtained in apparently pure culture, and its morphological and cultural reactions worked out as described below

The oval sporing organism thus recovered, when introduced into a fresh meat broth tube and incubated at 37° C anaerobically, in two or three days emitted the characteristic wound odour, and the meat began to blacken and diminish in volume, indicating active proteolysis This at once suggested the possible rôle played by this bacillus in the case of wounds —viz, that under suitable conditions for active growth and proliferation it did in the dead wound tissues what it appeared to do *in vitro*—viz, it digested them

Looking at the organism from this point of view, we came to the conclusion that it was in reality the active and probably the sole agent concerned in the cleansing of wounds that did well, and that where it was absent the wound remained refractory to salt-pack treatment and acted as if an antiseptic were being used instead of salt As the organism, however, belonged to the same group as *B œdematis maligni* and *B tetani* it was still looked on with suspicion in view of the universal horror of the presence of anaerobic spore bearers in a wound, and the natural desire on the part of the surgeon to get rid of such with all possible haste

BACTERIOLOGICAL AND CLINICAL OBSERVATIONS ON THE ORGANISM

Experiments were undertaken by one of us (R D) from which the organism was found to be non pathogenic to the animals employed, and from which, further, it could be assumed that the culture medium in which the organism had been grown for varying periods of time apparently contained no elements toxic to those animals

Taking these facts into consideration, together with the fact that it was apparently present judging from the smell, and as a result of bacteriological investigation in all the cases which pursued a normal course, and where no harm seemed to come from it, it was felt by us that it would be legitimate actually to introduce the anaerobe in living culture into a wound which had previously been treated with salt pack but which had failed to smell or to improve Such a case presented itself, and after making cultures from the wound to determine the absence of the organism one of us (R D) introduced a living culture, while the other (L J) carried out his usual method of salt packing In three days' time the patient's temperature had come down, the wound was emitting a foul and characteristic odour, and the patient was comfortable In a day or two after removal of the salt pack the wound was absolutely clean, devoid of all sloughs, a brilliant scarlet colour like fresh beef, and was covered with healthy granulations This case was its own control It had previously been packed in the usual way with salt bags, it did not smell thereafter, the patient did not improve, and the particular anaerobe described below was absent in culture It was repacked with salt as before, with one added factor—viz, the introduction of the spore-bearer in question

With these facts before us we concluded that the organism which we had introduced was in all probability the vital factor in determining the success on the second occasion of packing Since then other cases have been encountered in which the salt bag did not alter the patient's condition for the better and which did not smell. These have been sown in the same way with the living culture after first making cultures from the wound to determine its absence from that wound before sowing The wound has then been repacked in the usual way and has invariably done well and afforded nasal proof of the active presence of the organism.

MODE OF ACTION OF SALT PACKS

The question then arose as to the rôle played by the salt, and we felt that possibly the tight packing with salt bags, together with the subsequent outflow of fluid and the collection of pus that accumulated in the packing, acted rather by reason of its rendering the wound more or less anaerobic than by any inherent virtue possessed by the salt, either as a germicide or in view of its supposed lymphagogic action To determine this point certain cases were chosen, sown with a living culture of the organism and bags containing nothing but an inert substance—viz, sphagnum moss—were introduced in the same way as the salt bags so as to lie in contact with every part of the wound and to fill up the cavity completely We felt that as pus and fluid accumulated the moss would swell out and so mould itself more closely to the form of the wound while at the same time all interstices would become filled with fluid. In this way we should render the wound more or less anaerobic, and so afford the most favourable conditions for the growth of the anaerobe At the same time the element of salt would be eliminated

As we anticipated, the cases so treated followed exactly the same course as those in which the organism had been sown, but where the usual salt bag had been used

Hence we come to the conclusion that salt is not necessary in the treatment of wounds, and where salt packs are employed they act more by rendering the wound anaerobic, so providing favourable conditions for the growth of the organism where that organism is present When the latter is already present it gets to work, and the case goes on to a satisfactory termination Where the organism is absent the salt pack, in spite of the salt and all its supposed lymphagogic action, is useless in cleaning the wound or improving the patient's condition We arrive therefore at a point where we can recommend the employment of a method of wound treatment which involves the simplest of technique, the simplest and cheapest of dressings for salt or sphagnum moss can easily be had, and the least disturbance to the patient It does away with the need for frequent dressing and the mental and physical suffering entailed thereby

In order to ensure this result however, it is necessary that the organism or its spores be present, and although it appears to be frequently present it cannot be depended on to be so Hence in such cases the wound ought to be sown with the organism at the time of packing

As it is a spore bearer and an anaerobe, supplies of it could easily be kept in small ampoules or glass capsules which could be broken over the wound, thus setting free the spores

Since coming to these conclusions, we have further investigated bacteriologically the flora of wounds that have done well and have smelt and we have invariably recovered this organism, as we have, of course, done in the cases which were sown of set purpose

It is true that we have had no acute cases of gas gangrene to treat in this series, although the wounds so treated have been large, filthy, and sloughy, and we cannot say

all who have adopted this method, that a powerful and most offensive odour was emitted from the salt-packed wound Girling Ball,[1] for example, to quote one, says that the "foul odour is not an indication for changing the plug" Others say that the odour is a signal for change of dressing No one attempts an explanation except in one paper[2] we have read where the view is expressed that it is due to a "decomposition in the dressings themselves" It was noted, however, by one of us (L J) in the course of clinical work that one or two of those cases which failed to improve were also devoid of this peculiarly offensive fœtid odour, and on recalling one or two previous cases that had not progressed satisfactorily it was remembered that they too were devoid of odour

On considering together this phenomenon, and its possible explanation, we came to the conclusion that probably in the evil smelling but successful cases there was present a bacterium which was absent from those which did badly and which did not smell The idea was at first conceived that the salt pack might produce physical conditions in the wound which favoured the growth of this bacterium, and that the good results of the treatment might be directly due to its activity Taking everything into consideration, it was thought by one of us (R D) that the organism present was most likely to be an anaerobe, and steps were accordingly taken to determine the presence or absence of such an anaerobe or anaerobes A case was chosen from which the salt pack was about to be removed This case was one which had obviously done well under the treatment and which emitted a most offensive odour From the pus obtained from the wound two anaerobes were isolated in symbiosis one with round terminal spores in very small numbers, and the other a bacillus having a large subterminal oval spore The latter was present in large excess over the round sporing bacillus

The meat-broth tube in which the pus had been cultivated obviously contained a mixture, and as that tube showed evidence of active proteolysis and emitted the same powerful offensive odour as the wounds did, it was felt that the organism present in predominant numbers was responsible

After two attempts, made as already described by one of us (R D) in THE LANCET,[3] the oval sporing bacillus was obtained in apparently pure culture, and its morphological and cultural reactions worked out as described below

The oval sporing organism thus recovered, when introduced into a fresh meat broth tube and incubated at 37° C anaerobically, in two or three days emitted the characteristic wound odour, and the meat began to blacken and diminish in volume, indicating active proteolysis This at once suggested the possible rôle played by this bacillus in the case of wounds —viz, that under suitable conditions for active growth and proliferation it did in the dead wound tissues what it appeared to do *in vitro*—viz, it digested them

With these facts before us we concluded that the organism which we had introduced was in all probability the vital factor in determining the success on the second occasion of packing Since then other cases have been encountered in which the salt bag did not alter the patient's condition for the better and which did not smell. These have been sown in the same way with the living culture after first making cultures from the wound to determine its absence from that wound before sowing The wound has then been repacked in the usual way and has invariably done well and afforded nasal proof of the active presence of the organism

MODE OF ACTION OF SALT PACKS

The question then arose as to the rôle played by the salt, and we felt that possibly the tight packing with salt bags, together with the subsequent outflow of fluid and the collection of pus that accumulated in the packing, acted rather by reason of its rendering the wound more or less anaerobic than by any inherent virtue possessed by the salt, either as a germicide or in view of its supposed lymphagogic action To determine this point certain cases were chosen, sown with a living culture of the organism and bags containing nothing but an inert substance—viz, sphagnum moss—were introduced in the same way as the salt bags so as to lie in contact with every part of the wound and to fill up the cavity completely We felt that as pus and fluid accumulated the moss would swell out and so mould itself more closely to the form of the wound, while at the same time all interstices would become filled with fluid In this way we should render the wound more or less anaerobic, and so afford the most favourable conditions for the growth of the anaerobe At the same time the element of salt would be eliminated

As we anticipated, the cases so treated followed exactly the same course as those in which the organism had been sown, but where the usual salt bag had been used.

Hence we come to the conclusion that salt is not necessary in the treatment of wounds, and where salt packs are employed they act more by rendering the wound anaerobic, so providing favourable conditions for the growth of the organism where that organism is present When the latter is already present it gets to work, and the case goes on to a satisfactory termination Where the organism is absent the salt pack, in spite of the salt and all its supposed lymphagogic action, is useless in cleaning the wound or improving the patient's condition We arrive therefore at a point where we can recommend the employment of a method of wound treatment which involves the simplest of technique, the simplest and cheapest of dressings for salt or sphagnum moss can easily be had, and the least disturbance to the patient. It does away with the need for frequent dressing and the mental and physical suffering entailed thereby

In order to ensure this result however, it is necessary that the organism or its spores be present, and although it appears to be frequently present it cannot be depended on to be so Hence in such cases the wound ought to be sown with the organism at the time of packing

As it is a spore bearer and an anaerobe, supplies of it could easily be kept in small ampoules or glass capsules which could be broken over the wound, thus setting free the spores

Since coming to these conclusions, we have further investigated bacteriologically the flora of wounds that have done well and have smelt, and we have invariably recovered this organism, as we have, of course, done in the cases which were sown of set purpose

It is true that we have had no acute cases of gas gangrene to treat in this series, although the wounds so treated have been large, filthy, and sloughy, and we cannot say

from personal knowledge how it would act in such. We can, however, point to the published experience of several observers[4] who have used the salt-pack treatment with marked success in cases of gas infections from which *B perfringens* has been isolated This evidence leads us to believe that in acute cases of gas infection the presence of the organism we describe together with salt or sphagnum moss pack is likely to be attended with the same good result as in septic wounds showing no clinical evidence of gas infection We reach therefore a somewhat paradoxical conclusion—viz. that septic wounds can be successfully treated by sowing in them another spore-bearing anaerobe and thereafter rendering the wound more or less anaerobic. It certainly sounds like rank heresy and yet the evidence we adduce is too *strong to be* disregarded

IMPORTANCE OF DEAD TISSUE IN THE WOUND

Now it is common knowledge that the danger of a wound, apart from actual destruction by the inflicting trauma, is the *entry into* that wound of pathogenic organisms Since Lister s time the destruction of the invading germ has engrossed men's minds and by means of all kinds of antiseptics it has been sought to combat the infection Endeavour to achieve this end in this way has within the last two and a half years given way to attempts to fight the evil by using the patient s own protective forces—the so-called physiological method. The recognition that the body must take its part in the struggle and do the necessary work of repair is the merit of the advocates of saline The advantage, however does *not consist* in the action of saline as described by its originators and that the saline treatment of Wright has had to yield ground considerably since its *inception* is proved by the increasing frequency with which total excision of the wound is being resorted to

Throughout all these years of observation and work in wound infection the importance of the dead tissues present in the wound has been neglected or relegated to a secondary place

The view is now rapidly gaining ground that the dead tissue is the all important factor It is from this as a base that pathogenic organisms *elaborate the toxins* with which they gradually lower the patient s resistance and from which some of them make sundry excursions into the patient s body The toxins may either be specific toxins elaborated by the germs themselves or they may be formed as a result of the splitting up of the *dead tissue* by the vital action of these germs Destroy the base—the *submarine* base so to speak—from which these germs derive their supplies and the source of the undermining poison is cut off Antiseptics do not achieve this They may kill a few of the germs but even though they eradicate the infection it is not for a considerable time for their use implies *an added* trauma to the tissues The physiological method does not necessarily inflict a fresh trauma but leaves the body by its own forces to overcome the infection and to cast off the dead tissue

This takes time and as long as the basis of *supply* is left it is a perpetual source of danger Recognising this the tendency of surgery is now as we have indicated to remove the dead material by the knife—to excise the wound, in other words But the exact amount of dead material cannot always be appraised with the naked eye and moreover the very act of excision inflicts a fresh trauma liable to become immediately re infected Further, this is a gross and mutilating form of attack, and for anatomical reasons is not always possible A consideration of the histological features of gunshot wounds has led Bashford[5] practically to advocate immediate excision impressed as he is by the almost constant presence of anaerobic organisms in relation to the dead tissues Our whole knowledge of anaerobes however is imperfect and chaotic So many of them being practically saprophytes produce potent poisons as a result of their activity on dead tissue that all are indiscriminately condemned The organism which we describe here however is apparently one of the exceptions It is apparently non pathogenic does not produce toxins inimical to the human body and does not apparently attack living tissues At the same time however it appears to be able rapidly to break down dead tissue without in doing so producing toxics and this is proved amongst other things by the appearance of the shreds of slough remaining in the wound after removal of the salt bag These look thin almost transparent, and generally wash away easily under slight irrigation

This organism can dissect away the macroscopic and microscopic dead tissue in a way that no surgeon s knife ever can, and that without at the same time producing any further trauma The devitalised tissues are practically all removed in a few days, and with their destruction the breeding ground of the pathogenic germs is destroyed, while the living tissues, relieved of the strain of ever combating the increasing infection while trying to cast off the devitalised tissue, is able to turn its energies to repair, as evidenced by the rapid formation of healthy, strong granulations

DESCRIPTION OF METHOD OF TREATMENT

We should like to emphasise again the extreme importance of the presence of devitalised tissue in a wound , and no wound can be inflicted without a certain amount of devitalisation, whether microscopic or macroscopic

There are certain points, however, to which it is necessary to draw attention in the treatment of these wounds, and they are points which must be borne in mind

The most important and fundamental is the need *to lay* open a wound in the *most thorough manner* possible *It is* a point that is not always carried out, but it is *essential* Whether obviously dead tissue is cut away or not at the same time is, with the method of treatment we advocate, not absolutely necessary, but it is all important to lay open every pocket so that the packing will be in contact everywhere with the walls of the wound. As the *wounds are so* often irregular and burrowing, this will call for the ingenuity of the surgeon in each case All foreign bodies must likewise be removed and any grossly damaged tissue may at the same time be removed

The interior of the wound is now irrigated with sterile water or saline to wash away obvious pus or blood, and the living culture of the organism is now sown in the wound Hitherto we have used a pipette for the purpose Immediately thereafter the packs whether of salt or of sphagnum moss are introduced into the wound so as to come in contact with every part of it Just before introduction the packs are moistened with sterile water or saline Over this several layers of plain gauze are laid after slightly soaking in the same way The wound is thus completely and firmly packed and over all a thick layer *of* cotton wool, after which the whole is firmly bandaged It is an *additional help* to steady the limb by means of a splint The packing itself however acts as a splint as we shall see in the sequel Where salt has been used the patient has some slight pain for a few hours and whatever pack has been used the temperature will probably rise even *higher than* it was before interference with the wound

For the first 24 hours, if salt has been used, there is a very copious discharge of fluid doubtless due to the concentration of salt in the wound Thereafter the flow ceases presumably as a result of reduced salt concentration A certain amount of pus oozes away and towards *the end* of the second day or at latest the third day, the wound begins to smell in cases which have been unsown but where the organism has been *present* This corresponds more or less closely to what occurs *in vitro* A culture sown in meat broth from the sporing form does not begin to smell much till the end of the second or till the third day and probably means the length of time needed for the spores present to germinate sufficiently for the proliferating organism to attack the dead tissue in sufficient numbers to be able to cause the smell At the same time as has been noted by nearly all who have written on the salt bag treatment the temperature begins to come down towards the end of the second or third day and thereafter, as a rule stays down This seems to coincide with the *production* of the foul odour If in an unsown case where salt bags are used by the third or at latest the fourth day the temperature shows no signs *of* subsiding and the *wound does* not emit the offensive stench it is not doing well and is not going to do well under that treatment and it is a signal for the sowing of the wound with the living organism Where on the other hand the characteristic smell is markedly present and yet there is no fall in the temperature *look for* some other focus of infection or some other wound perhaps slight and consequently treated by one of the old antiseptics

From the third day onward the patient steadily improves There is no daily dressing to worry him, except perhaps the

all who have adopted this method, that a powerful and most offensive odour was emitted from the salt-packed wound Girling Ball,[1] for example, to quote one, says that the "foul odour is not an indication for changing the plug" Others say that the odour is a signal for change of dressing No one attempts an explanation except in one paper[2] we have read where the view is expressed that it is due to a "decomposition in the dressings themselves" It was noted, however, by one of us (L J) in the course of clinical work that one or two of those cases which failed to improve were also devoid of this peculiarly offensive fœtid odour, and on recalling one or two previous cases that had not progressed satisfactorily it was remembered that they too were devoid of odour

On considering together this phenomenon, and its possible explanation, we came to the conclusion that probably in the evil smelling but successful cases there was present a bacterium which was absent from those which did badly and which did not smell The idea was at first conceived that the salt pack might produce physical conditions in the wound which favoured the growth of this bacterium, and that the good results of the treatment might be directly due to its activity Taking everything into consideration, it was thought by one of us (R D) that the organism present was most likely to be an anaerobe, and steps were accordingly taken to determine the presence or absence of such an anaerobe or anaerobes A case was chosen from which the salt pack was about to be removed This case was one which had obviously done well under the treatment and which emitted a most offensive odour From the pus obtained from the wound two anaerobes were isolated in symbiosis one with round terminal spores in very small numbers, and the other a bacillus having a large subterminal oval spore The latter was present in large excess over the round sporing bacillus

The meat-broth tube in which the pus had been cultivated obviously contained a mixture, and as that tube showed evidence of active proteolysis and emitted the same powerful offensive odour as the wounds did, it was felt that the organism present in predominant numbers was responsible

After two attempts, made as already described by one of us (R D) in THE LANCET,[3] the oval sporing bacillus was obtained in apparently pure culture, and its morphological and cultural reactions worked out as described below

The oval sporing organism thus recovered, when introduced into a fresh meat broth tube and incubated at 37° C anaerobically, in two or three days emitted the characteristic wound odour, and the meat began to blacken and diminish in volume, indicating active proteolysis This at once suggested the possible rôle played by this bacillus in the case of wounds—viz, that under suitable conditions for active growth and proliferation it did in the dead wound tissues what it appeared to do *in vitro*—viz, it digested them

Looking at the organism from this point of view, we came to the conclusion that it was in reality the active and probably the sole agent concerned in the cleansing of wounds that did well, and that where it was absent the wound remained refractory to salt pack treatment and acted as if an antiseptic were being used instead of salt As the organism, however belonged to the same group as *B œdematis maligni* and *B tetani* it was still looked on with suspicion in view of the universal horror of the presence of anaerobic spore bearers in a wound, and the natural desire on the part of the surgeon to get rid of such with all possible haste

BACTERIOLOGICAL AND CLINICAL OBSERVATIONS ON THE ORGANISM

Experiments were undertaken by one of us (R D) from which the organism was found to be non pathogenic to the animals employed, and from which, further, it could be assumed that the culture medium in which the organism had been grown for varying periods of time apparently contained no elements toxic to those animals

Taking these facts into consideration, together with the fact that it was apparently present, judging from the smell, and as a result of bacteriological investigation in all the cases which pursued a normal course, and where no harm seemed to come from it, it was felt by us that it would be legitimate actually to introduce the anaerobe in living culture into a wound which had previously been treated with salt pack but which had failed to smell or to improve Such a case presented itself, and after making cultures from the wound to determine the absence of the organism one of us (R D) introduced a living culture, while the other (L J) carried out his usual method of salt packing In three days' time the patient's temperature had come down, the wound was emitting a foul and characteristic odour, and the patient was comfortable In a day or two after removal of the salt pack the wound was absolutely clean, devoid of all sloughs, a brilliant scarlet colour like fresh beef, and was covered with healthy granulations This case was its own control It had previously been packed in the usual way with salt bags, it did not smell thereafter, the patient did not improve, and the particular anaerobe described below was absent in culture It was repacked with salt as before, with one added factor—viz, the introduction of the spore-bearer in question

With these facts before us we concluded that the organism which we had introduced was in all probability the vital factor in determining the success on the second occasion of packing Since then other cases have been encountered in which the salt bag did not alter the patient's condition for the better and which did not smell. These have been sown in the same way with the living culture after first making cultures from the wound to determine its absence from that wound before sowing The wound has then been repacked in the usual way and has invariably done well and afforded nasal proof of the active presence of the organism.

MODE OF ACTION OF SALT PACKS

The question then arose as to the rôle played by the salt, and we felt that possibly the tight packing with salt bags, together with the subsequent outflow of fluid and the collection of pus that accumulated in the packing, acted rather by reason of its rendering the wound more or less anaerobic than by any inherent virtue possessed by the salt, either as a germicide or in view of its supposed lymphagogic action To determine this point certain cases were chosen, sown with a living culture of the organism and bags containing nothing but an inert substance—viz, sphagnum moss—were introduced in the same way as the salt bags so as to lie in contact with every part of the wound and to fill up the cavity completely We felt that as pus and fluid accumulated the moss would swell out and so mould itself more closely to the form of the wound, while at the same time all interstices would become filled with fluid In this way we should render the wound more or less anaerobic, and so afford the most favourable conditions for the growth of the anaerobe At the same time the element of salt would be eliminated

As we anticipated, the cases so treated followed exactly the same course as those in which the organism had been sown, but where the usual salt bag had been used.

Hence we come to the conclusion that salt is not necessary in the treatment of wounds, and where salt packs are employed they act more by rendering the wound anaerobic, so providing favourable conditions for the growth of the organism where that organism is present When the latter is already present it gets to work, and the case goes on to a satisfactory termination Where the organism is absent the salt pack, in spite of the salt and all its supposed lymphagogic action, is useless in cleaning the wound or improving the patient's condition We arrive therefore at a point where we can recommend the employment of a method of wound treatment which involves the simplest of technique, the simplest and cheapest of dressings for salt or sphagnum moss can easily be had, and the least disturbance to the patient. It does away with the need for frequent dressing and the mental and physical suffering entailed thereby

In order to ensure this result however, it is necessary that the organism or its spores be present, and although it appears to be frequently present it cannot be depended on to be so Hence in such cases the wound ought to be sown with the organism at the time of packing

As it is a spore bearer and an anaerobe, supplies of it could easily be kept in small ampoules or glass capsules which could be broken over the wound, thus setting free the spores

Since coming to these conclusions, we have further investigated bacteriologically the flora of wounds that have done well and have smelt, and we have invariably recovered this organism, as we have, of course, done in the cases which were sown of set purpose

It is true that we have had no acute cases of gas gangrene to treat in this series, although the wounds so treated have been large, filthy, and sloughy, and we cannot say

from personal knowledge how it would act in such We can, however, point to the published experience of several observers[4] who have used the salt-pack treatment with marked success in cases of gas infections from which *B perfringens* has been isolated This evidence leads us to believe that in acute cases of gas infection the presence of the organism we describe together with salt or sphagnum moss pack is likely to be attended with the same good result as in septic wounds showing no clinical evidence of gas infection We reach therefore, a somewhat paradoxical conclusion—viz. that septic wounds can be successfully treated by sowing in them another spore bearing anaerobe and thereafter rendering the wound more or less anaerobic It certainly sounds like rank heresy and yet the evidence we adduce is too strong to be disregarded

Importance of Dead Tissue in the Wound

Now it is common knowledge that the danger of a wound, apart from actual destruction by the inflicting trauma, is the entry into that wound of pathogenic organisms Since Lister's time the destruction of the invading germ has engrossed men's minds, and by means of all kinds of antiseptics it has been sought to combat the infection Endeavour to achieve this end in this way has within the last two and a half years given way to attempts to fight the evil by using the patient's own protective forces—the so called physiological method The recognition that the body *must take its part* in the struggle and do the necessary work of repair is the merit of the advocates of saline The advantage, however, does not consist in the action of saline as described by its originators, and that the saline treatment of Wright has had to yield ground considerably since its inception is proved by the increasing frequency with which *total excision* of the wound is being resorted to

Description of Method of Treatment

We should like to emphasise again the extreme importance of the presence of devitalised tissue in a wound , and no wound can be inflicted without a certain amount of devitalisation, whether microscopic or macroscopic

There are certain points, however, to which it is necessary to draw attention in the treatment of these wounds, and they are points which must be borne in mind

The most important and fundamental is the need to lay open a wound in the most thorough manner possible It is a point that is not always carried out, but it is essential Whether obviously dead tissue is cut away or not at the same time is, with the method of treatment we advocate, not absolutely necessary, but it is all important to lay open *every pocket so that* the packing will be in contact everywhere with the walls of the wound. As the wounds are so often irregular and burrowing, this will call for the ingenuity of the surgeon in each case All foreign bodies must likewise be removed, and any grossly damaged tissue may at the same time be removed

The interior of the wound is now irrigated with sterile water or saline to wash away obvious pus or blood, and the living culture of the organism is now sown in the wound Hitherto we have used a pipette for the purpose Immediately thereafter the packs, whether of salt or of sphagnum moss are introduced into the wound so as to come in contact with every part of it Just before introduction the packs are moistened with sterile water or saline Over this several layers of plain gauze are laid after slightly soaking in the same way The wound is thus completely and firmly packed and over all a thick layer of cotton wool, after which the whole is firmly bandaged It is an additional help to steady the limb by means of a splint The packing itself, however, acts as a splint as we shall see in the sequel Where salt has been used the patient has some slight pain for a few hours, and whatever pack has been used the temperature will probably rise even higher than it was before interference with the wound

For the first 24 hours, if salt has been used, there is a very copious discharge of fluid doubtless due to the concentration of salt in the wound Thereafter the flow ceases presumably as a result of reduced salt concentration A certain amount of pus oozes away and towards the end of the second day or at latest the third day, the wound begins to smell in cases which have been unsown but where the organism has been present. This corresponds more or less closely to what occurs *in vitro* A culture sown in meat broth from the sporing form does not begin to smell much till the end of the second or till the third day, and probably means the length of time needed for the spores present to germinate sufficiently for the proliferating organism to attack the dead tissue in sufficient numbers to be able to cause the smell At the same time, as has been noted by nearly all who have written on the salt bag treatment the temperature begins to come down towards the end of the second or third day and thereafter as a rule stays down This seems to coincide with the production of the foul odour If in an unsown case where salt bags are used by the third or at latest the fourth day the temperature shows no signs of subsiding and the wound does not emit the offensive stench it is not doing well and is not going to do well under that treatment and it is a signal for the sowing of the wound with the living organism Where on the other hand, the characteristic smell is markedly present and yet there is no fall in the temperature look for some other focus of infection or some other wound, perhaps slight and consequently treated by one of the old antiseptics

From the third day onward the patient steadily improves There is no daily dressing to worry him, except perhaps the

all who have adopted this method, that a powerful and most offensive odour was emitted from the salt-packed wound Girling Ball,[1] for example, to quote one, says that the "*foul odour* is not an indication for changing the plug" Others say that the odour is a signal for change of dressing No one attempts an explanation except in one paper[2] we have read where the view is expressed that it is due to a "decomposition in the dressings themselves" It was noted, however, by one of us (L J) in the course of clinical work that one or two of those cases which failed to improve were also devoid of this peculiarly offensive fœtid odour, and on recalling one or two previous cases that had not progressed satisfactorily it was remembered that they too were devoid of odour

On considering together this phenomenon, and its possible explanation, we came to the conclusion that probably in the evil smelling but successful cases there was present a bacterium which was absent from those which did badly and which did not smell The idea was at first conceived that the salt pack might produce physical conditions in the wound which favoured the growth of this bacterium, and that the good results of the treatment might be directly due to its activity Taking everything into consideration, it was thought by one of us (R D) that the organism present was most likely to be an anaerobe, and steps were accordingly taken to determine the presence or absence of such an anaerobe or anaerobes A case was chosen from which the salt pack was about to be removed This case was one which had obviously done well under the treatment and which emitted a most offensive odour From the pus obtained from the wound two anaerobes were isolated in symbiosis one with round terminal spores in very small numbers, and the other a bacillus having a large subterminal oval spore The latter was present in large excess over the round sporing bacillus

The meat-broth tube in which the pus had been cultivated obviously contained a mixture, and as that tube showed evidence of active proteolysis and emitted the same powerful offensive odour as the wounds did, it was felt that the organism present in predominant numbers was responsible

After two attempts, made as already described by one of us (R D) in THE LANCET,[3] the oval *sporing* bacillus was obtained in apparently pure culture, and its morphological and cultural reactions worked out as described below

The oval sporing organism thus recovered, when introduced into a fresh meat-broth tube and incubated at 37° C anaerobically, in two or three days emitted the characteristic wound odour, and the meat began to blacken and diminish in volume, indicating active proteolysis This at once suggested the possible rôle played by this bacillus in the case of wounds —viz, that under suitable conditions for active growth and proliferation it did in the dead wound tissues what it appeared to do *in vitro*—viz, it digested them.

Looking at the organism from this point of view, we came to the conclusion that it was in reality the active and probably the sole agent concerned in the cleansing of wounds that did well, and that where it was absent the wound remained refractory to salt pack treatment and acted as if an antiseptic were being used instead of salt. As the organism, however, belonged to the same group as *B œdematis maligni* and *B tetani* it was still looked on with suspicion in view of the universal horror of the presence of anaerobic spore bearers in a wound, and the natural desire on the part of the surgeon to get rid of such with all possible haste

BACTERIOLOGICAL AND CLINICAL OBSERVATIONS ON THE ORGANISM

Experiments were undertaken by one of us (R D) from which the organism was found to be non pathogenic to the animals employed, and from which, further, it could be assumed that the culture medium in which the organism had been grown for varying periods of time apparently contained no elements toxic to those animals

Taking these facts into consideration, together with the fact that it was apparently present, judging from the smell, and as a result of bacteriological investigation in all the cases which pursued a normal course, and where no harm seemed to come from it, it was felt by us that it would be legitimate actually to introduce the anaerobe in living culture into a wound which had previously been treated with salt pack but which had failed to smell or to improve Such a case presented itself, and after making cultures from the wound to determine the absence of the organism one of us (R D) introduced a living culture, while the other (L J) carried out his usual method of salt packing In three days' time the patient's temperature had come down, the wound was *emitting* a foul and characteristic odour, and the patient was comfortable In a day or two after removal of the salt pack the wound was absolutely clean, devoid of all sloughs, a brilliant scarlet colour like fresh beef, and was covered with healthy granulations This case was its own control. It had previously been packed in the usual way with salt bags, it did not smell thereafter, the patient did not improve, and the particular anaerobe described below was absent in culture It was repacked with salt as before, with one added factor—viz, the introduction of the spore-bearer in question

With these facts before us we concluded that the organism which we had introduced was in all probability the vital factor in determining the success on the second occasion of packing Since then other cases have been encountered in which the salt bag did not alter the patient's condition for the better and which did not smell These have been sown in the same way with the living culture after first making cultures from the wound to determine its absence from that wound before sowing The wound has then been repacked in the usual way and has invariably done well and afforded nasal proof of the active presence of the organism

MODE OF ACTION OF SALT PACKS

The question then arose as to the rôle played by the salt, and we felt that possibly the tight packing with salt bags, together with the subsequent outflow of fluid and the collection of pus that accumulated in the packing, acted rather by reason of its rendering the wound more or less anaerobic than by any inherent virtue possessed by the salt, either as a germicide or in view of its supposed lymphagogic action To determine this point certain cases were chosen, sown with a living culture of the organism and bags containing nothing but an inert substance—viz, sphagnum moss—were introduced in the same way as the salt bags so as to lie in contact with every part of the wound and to fill up the cavity completely We felt that as pus and fluid accumulated the moss would swell out and so mould itself more closely to the form of the wound, while at the same time all interstices would become filled with fluid In this way we should render the wound more or less anaerobic, and so afford the most favourable conditions for the growth of the anaerobe At the same time the element of salt would be eliminated

As we anticipated, the cases so treated followed exactly the same course as those in which the organism had been sown, but where the usual salt bag had been used.

Hence we come to the conclusion that salt is not necessary in the treatment of wounds, and where salt packs are employed they act more by rendering the wound anaerobic, so providing favourable conditions for the growth of the organism where that organism is present When the latter is already present it gets to work, and the case goes on to a satisfactory termination Where the organism is absent the salt pack, in spite of the salt and all its supposed lymphagogic action, is useless in cleaning the wound or improving the patient's condition We arrive therefore at a point where we can recommend the employment of a method of wound treatment which involves the simplest of technique, the simplest and cheapest of dressings for salt or sphagnum moss can easily be had, and the least disturbance to the patient. It does away with the need for frequent dressing and the mental and physical suffering entailed thereby

In order to ensure this result however, it is necessary that the organism or its spores be present, and although it appears to be frequently present it cannot be depended on to be so Hence in such cases the wound ought to be sown with the organism at the time of packing

As it is a spore bearer and an anaerobe, supplies of it could easily be kept in small ampoules or glass capsules which could be broken over the wound, thus setting free the spores

Since coming to these conclusions, we have further investigated bacteriologically the flora of wounds that have done well and have smelt and we have invariably recovered this organism, as we have, of course, done in the cases which were sown of set purpose

It is true that we have had no acute cases of gas gangrene to treat in this series, although the wounds so treated have been large, filthy, and sloughy, and we cannot say

from personal knowledge how it would act in such. We can, however, point to the published experience of several observers[1] who have used the salt-pack treatment with marked success in cases of gas infections from which *B perfringens* has been isolated This evidence leads us to believe that in acute cases of gas infection the presence of the organism we describe together with salt or sphagnum moss pack is likely to be attended with the same good result as in septic wounds showing no clinical evidence of gas infection We reach therefore a somewhat paradoxical conclusion—viz. that septic wounds can be successfully treated by sowing in them another spore-bearing anaerobe and thereafter rendering the wound more or less anaerobic It certainly sounds like rank heresy and yet the evidence we adduce is too strong to be disregarded.

IMPORTANCE OF DEAD TISSUE IN THE WOUND

Now it is common knowledge that the danger of a wound, apart from actual destruction by the inflicting trauma, is the entry into that wound of pathogenic organisms Since Lister's time the destruction of the invading germ has engrossed men's minds, and by means of all kinds of antiseptics it has been sought to combat the infection Endeavour to achieve this end in this way has within the last two and a half years given way to attempts to fight the evil by using the patient's own protective forces—the so-called physiological method. The recognition that the body must take its part in the struggle and do the necessary work of repair is the merit of the advocates of saline The advantage, however does not consist in the action of saline as described by its originators and that the saline treatment of Wright has had to yield ground considerably since its inception is proved by the increasing frequency with which total excision of the wound is being resorted to

Throughout all these years of observation and work in wound infection the importance of the dead tissues present in the wound has been neglected or relegated to a secondary place

The view is now rapidly gaining ground that the dead tissue is the all important factor It is *from this as a base* that pathogenic organisms elaborate the toxins with which they gradually lower the patient's resistance and from which some of them make sundry excursions into the patient's body The toxins may either be specific toxins elaborated by the germs themselves *or they may be formed as* a result of the splitting up of the dead tissue *by the vital* action of these germs Destroy the base—the submarine base *so to* speak—from which these germs derive their supplies and the source of the undermining poison is cut off Antiseptics do not achieve this *They may kill a few of the* germs but even though they eradicate the infection it is not for a considerable time for their use implies an added *trauma to the tissues* The physiological method does not necessarily inflict a fresh trauma but leaves the body by its own force to overcome the infection and to cast off the dead tissue

This takes time and as long as the basis of *supply* is left it is a perpetual source of danger Recognising this the tendency of surgery is now as we have indicated to remove the dead material *by the knife*—to excise the wound in other words But the exact amount of dead material cannot always be appraised with the naked eye and moreover the very act of excision inflicts a fresh trauma liable to become immediately re infected Further this is a gross and mutilating form of attack and for anatomical reasons is not always possible A consideration of the histological features of gunshot wounds has led Bashford practically to advocate immediate excision impressed as he is by the almost constant presence of anaerobic organisms in relation to the dead tissues Our whole knowledge of anaerobes however is imperfect and chaotic. So many of them being practically saprophytes produce potent poisons as a result of their activity on dead tissue that all are indiscriminately condemned The organism which we describe here however is apparently one of the exceptions It is apparently non pathogenic does not produce toxins inimical to the human body and does not apparently attack living tissues At the same time however it appears to be able rapidly to break down dead tissue without in doing so producing toxins and this is proved amongst other things by the appearance of the shreds of slough remaining in the wound after removal of the salt bag These look thin almost transparent, and generally wash away easily under *slight irrigation*

This organism can dissect away the macroscopic and microscopic dead tissue in a way that no surgeon's knife ever can, and that without at the same time producing any further trauma The devitalised tissues are practically all removed in a few days and with their destruction the breeding ground of the pathogenic germs is destroyed while the living tissues relieved of the strain of ever combating the increasing infection while trying to cast off the devitalised tissue, is able to turn its energies to repair, as evidenced by the rapid formation of healthy, strong granulations

DESCRIPTION OF METHOD OF TREATMENT

We should like to emphasise again the extreme importance of the presence of devitalised tissue in a wound, and no wound can be inflicted without a certain amount of devitalisation, whether microscopic or macroscopic

There are certain points, however to which it is necessary to draw attention in the treatment of these wounds, and they are points which must be borne in mind

The most important and fundamental is the need to lay open a wound in the most thorough manner possible It is a point that is not always carried out, but it is essential Whether obviously dead tissue is cut away or not at the same time is, with the method of treatment we advocate, not absolutely necessary but it is all important to lay open every pocket so that the packing will be in contact everywhere with the walls of the wound. As the wounds are so often irregular and burrowing, this will call for the ingenuity of the surgeon in each case All foreign bodies must likewise be removed and any grossly damaged tissue may at the same time be removed

The interior of the wound is now irrigated with sterile water or saline to wash away obvious pus or blood, and the living culture of the organism is now sown in the wound Hitherto we have used a pipette for the purpose Immediately thereafter the packs whether of salt or of sphagnum moss are introduced into the wound so as to come in contact with every part of it Just before introduction the packs are moistened with sterile water or saline Over this several layers of plain gauze are laid after slightly soaking in the same way The wound is thus completely and firmly packed and over-all a thick layer of cotton wool after which the whole is firmly bandaged It is an additional help to steady the limb by means of a splint The packing itself however acts as a splint as we shall see in the sequel Where salt has been used the patient has some slight pain for a few hours and whatever pack has been used the temperature will probably rise even higher than it was before interference with the wound

DESCRIPTION OF METHOD OF TREATMENT

We should like to emphasise again the extreme importance of the presence of devitalised tissue in a wound, and no wound can be inflicted without a certain amount of devitalisation, whether microscopic or macroscopic

There are certain points, however to which it is necessary to draw attention in the treatment of these wounds, and they are points which must be borne in mind

The most important and fundamental is the need to lay open a wound in the *most thorough manner* possible It is a point that is not always carried out, *but it is essential* Whether obviously dead tissue is cut away or not at the same time is, with the method of treatment we advocate, not absolutely necessary but it is all important to lay open every pocket *so* that the packing will be in contact everywhere with the walls of *the wound.* As the wounds are so often irregular and burrowing, this will call for the ingenuity of the surgeon in each case All foreign bodies must likewise be removed, and any grossly damaged tissue may at the same time be removed

The interior of the wound is now irrigated with sterile water or saline to wash away obvious pus or blood, and the living culture of the organism is now sown in the wound Hitherto we have used a pipette for the purpose Immediately thereafter the packs whether of salt or of sphagnum moss are introduced *into* the wound so as to come in contact with every part of it Just before introduction the packs are moistened with *sterile water or saline* Over this several layers of plain gauze are laid after slightly soaking in the same way The wound is thus completely and firmly packed and over-all a thick layer of cotton wool, after which the whole is firmly bandaged It is an additional help to steady the limb by means of a splint The packing itself, however acts as a splint as we shall see in the sequel Where salt has been used the patient has *some slight* pain for a few hours and whatever pack has been used the temperature will probably rise even higher than it was before *interference* with the wound

For the first 24 hours if salt has been used there is a very copious discharge of fluid doubtless due to the concentration of salt in the wound Thereafter the flow ceases presumably as a result of reduced salt concentration A certain amount of pus oozes away and towards the end of the second day *or* at latest the third day the wound begins to smell in cases which have been unsown but where the organism has been present This corresponds more or less closely to what occurs *in vitro* A culture sown in meat broth from the sporing form does not begin to smell much till the end of the second or till the third day and probably means the length of time needed for the spores present to germinate sufficiently for the proliferating organism to attack the dead tissue in sufficient numbers to be able to cause the smell At the same time as has been noted by nearly all who have written on the salt bag treatment the temperature begins *to come* down towards the end of the second or third day and thereafter as a rule stays down This seems to coincide with the production of the foul odour If in an unsown case where salt bags are used by the third or at latest the fourth day the temperature shows no signs of subsiding and the wound does not emit the offensive stench it is not doing well and is not *going* to do well under that treatment and it is a signal for the sowing of the wound with the living organism Where on the other hand the characteristic smell is markedly present and yet there is no fall in the temperature look for some other focus of infection or some other wound perhaps slight and consequently treated by one of the old antiseptics

From the third day onward the patient steadily improves There is no daily dressing to worry him except perhaps the all who have adopted this method, that a powerful and most offensive odour was emitted from the salt-packed wound Girling Ball,[1] for example, to quote one, says that the "foul odour is not an indication for changing the plug " Others say that the odour is a signal for change of dressing No one attempts an explanation except in one paper[2] we have read where the view is expressed that it is due to a "decomposition in the dressings themselves " It was noted, however, by one of us (L J) in the course of clinical work that one or two of those cases which failed to improve were also devoid of this peculiarly offensive fœtid odour, and on recalling one or two previous cases that had not progressed satisfactorily it was remembered that they too were devoid of odour

On considering together this phenomenon, and its possible explanation, we came to the conclusion that probably in the evil smelling but successful cases there was present a bacterium which was absent from those which did badly and which did not smell The idea was at first conceived that the salt pack might produce physical conditions in the wound which favoured the growth of this bacterium, and that the good results of the treatment might be directly due to its activity Taking everything into consideration, it was thought by one of us (R D) that the organism present was most likely to be an anaerobe, and steps were accordingly taken to determine the presence or absence of such an anaerobe or anaerobes A case was chosen from which the salt pack was about to be removed This case was one which had obviously done well under the treatment and which emitted a most offensive odour From the pus obtained from the wound two anaerobes were isolated in symbiosis one with round terminal spores in very small numbers, and the other a bacillus having a large subterminal oval spore The latter was present in large excess over the round sporing bacillus

The meat-broth tube in which the pus had been cultivated obviously contained a mixture, and as that tube showed evidence of active proteolysis and emitted the same powerful offensive odour as the wounds did, it was felt that the organism present in predominant numbers was responsible

After two attempts, made as already described by one of us (R D) in THE LANCET,[3] the oval sporing bacillus was obtained in apparently pure culture, and its morphological and cultural reactions worked out as described below

The oval sporing organism thus recovered, when introduced into a fresh meat broth tube and incubated at 37° C anaerobically, in two or three days emitted the characteristic wound odour, and the meat began to blacken and diminish in volume, indicating active proteolysis This at once suggested the possible rôle played by this bacillus in the case of wounds —viz , that under suitable conditions for active growth and proliferation it did in the dead wound tissues what it appeared to do *in vitro*—viz , it digested them

Looking at the organism from this point of view, we came to the conclusion that it was in reality the active and probably the sole agent concerned in the cleansing of wounds that did well, and that where it was absent the wound remained refractory to salt-pack treatment and acted as if an antiseptic were being used instead of salt. As the organism, however belonged to the same group as *B œdematis maligni* and *B tetani* it was still looked on with suspicion in view of the universal horror of the presence of anaerobic spore bearers in a wound, and the natural desire on the part of the surgeon to get rid of such with all possible haste

BACTERIOLOGICAL AND CLINICAL OBSERVATIONS ON THE ORGANISM

Experiments were undertaken by one of us (R D) from which the organism was found to be non pathogenic to the animals employed, and from which, further, it could be assumed that the culture medium in which the organism had been grown for varying periods of time apparently contained no elements toxic to those animals

Taking these facts into consideration, together with the fact that it was apparently present, judging from the smell and as a result of bacteriological investigation in all the cases which pursued a normal course, and where no harm seemed to come from it, it was felt by us that it would be legitimate actually to introduce the anaerobe in living culture into a wound which had previously been treated with salt pack but which had failed to smell or to improve Such a case presented itself, and after making cultures from the wound to determine the absence of the organism one of us (R D) introduced a living culture, while the other (L J) carried out his usual method of salt packing In three days' time the patient's temperature had come down, the wound was emitting a foul and characteristic odour, and the patient was comfortable In a day or two after removal of the salt pack the wound was absolutely clean, devoid of all sloughs, a brilliant scarlet colour like fresh beef, and was covered with healthy granulations This case was its own control It had previously been packed in the usual way with salt bags, it did not smell thereafter, the patient did not improve, and the particular anaerobe described below was absent in culture It was repacked with salt as before, with one added factor—viz , the introduction of the spore-bearer in question

With these facts before us we concluded that the organism which we had introduced was in all probability the vital factor in determining the success on the second occasion of packing Since then other cases have been encountered in which the salt bag did not alter the patient's condition for the better and which did not smell. These have been sown in the same way with the living culture after first making cultures from the wound to determine its absence from that wound before sowing The wound has then been repacked in the usual way and has invariably done well and afforded nasal proof of the active presence of the organism

MODE OF ACTION OF SALT PACKS

The question then arose as to the rôle played by the salt, and we felt that possibly the tight packing with salt bags, together with the subsequent outflow of fluid and the collection of pus that accumulated in the packing, acted rather by reason of its rendering the wound more or less anaerobic than by any inherent virtue possessed by the salt, either as a germicide or in view of its supposed lymphagogic action To determine this point certain cases were chosen, sown with a living culture of the organism and bags containing nothing but an inert substance—viz , sphagnum moss—were introduced in the same way as the salt bags so as to lie in contact with every part of the wound and to fill up the cavity completely We felt that as pus and fluid accumulated the moss would swell out and so mould itself more closely to the form of the wound, while at the same time all interstices would become filled with fluid In this way we should render the wound more or less anaerobic, and so afford the most favourable conditions for the growth of the anaerobe At the same time the element of salt would be eliminated

As we anticipated, the cases so treated followed exactly the same course as those in which the organism had been sown, but where the usual salt bag had been used

Hence we come to the conclusion that salt is not necessary in the treatment of wounds, and where salt packs are employed they act more by rendering the wound anaerobic, so providing favourable conditions for the growth of the organism where that organism is present When the latter is already present it gets to work, and the case goes on to a satisfactory termination Where the organism is absent the salt pack, in spite of the salt and all its supposed lymphagogic action, is useless in cleaning the wound or improving the patient's condition We arrive therefore at a point where we can recommend the employment of a method of wound treatment which involves the simplest of technique, the simplest and cheapest of dressings for salt or sphagnum moss can easily be had, and the least disturbance to the patient. It does away with the need for frequent dressing and the mental and physical suffering entailed thereby

In order to ensure this result however, it is necessary that the organism or its spores be present, and although it appears to be frequently present it cannot be depended on to be so Hence in such cases the wound ought to be sown with the organism at the time of packing

As it is a spore bearer and an anaerobe, supplies of it could easily be kept in small ampoules or glass capsules which could be broken over the wound, thus setting free the spores

Since coming to these conclusions, we have further investigated bacteriologically the flora of wounds that have done well and have smelt and we have invariably recovered this organism, as we have, of course, done in the cases which were sown of set purpose

It is true that we have had no acute cases of gas gangrene to treat in this series, although the wounds so treated have been large, filthy, and sloughy, and we cannot say

from personal knowledge how it would act in such. We can however, point to the published experience of several observers[4] who have used the salt-pack treatment with marked success in cases of gas infections from which *B perfringens* has been isolated This evidence leads us to believe that in acute cases of gas infection the presence of the organism we describe together with salt or sphagnum moss pack is likely to be attended with the same good result as in septic wounds showing no clinical evidence of gas infection We reach therefore, a somewhat paradoxical conclusion—viz. that septic wounds can be successfully treated by sowing in them another spore bearing anaerobe and thereafter rendering the wound more or less anaerobic It certainly sounds like rank heresy and yet the evidence we adduce is too strong to be disregarded

IMPORTANCE OF DEAD TISSUE IN THE WOUND

Now it is common knowledge that the danger of a wound, apart from actual destruction by the inflicting trauma, is the entry into that wound of pathogenic organisms Since Lister's time the destruction of the invading germ has engrossed men's minds, and by means of all kinds of antiseptics it has been sought to combat the infection Endeavour to achieve this end in this way has within the last two and a half years given way to attempts to fight the evil by using the patient's own protective forces—the so-called physiological method. The recognition that the body must take its part in the struggle and do the necessary work of repair is the merit of the advocates of saline The advantage however, does not consist in the action of saline as described by its originators, and that the saline treatment of Wright has had to yield ground considerably since its inception is proved by the increasing frequency with which total excision of the wound is being resorted to

Throughout all these years of observation and work in wound infection the importance of the dead tissues present in the wound has been neglected or relegated to a secondary place

The view is now rapidly gaining ground that the dead tissue is the all important factor It is from this as a base that pathogenic organisms elaborate the toxins with which they gradually lower the patient's resistance and from which some of them make sundry excursions into the patient's body The toxins may either be specific toxins elaborated by the germs themselves or they may be formed as a result of the splitting up of the dead tissue by the vital action of these germs Destroy the base—the submarine base so to speak—from which these germs derive their supplies and the source of the undermining poison is cut off. Antiseptics do not achieve this They may kill a few of the germs but even though they eradicate the infection it is not for a considerable time for their use implies an added trauma to the tissues The physiological method does not necessarily inflict a fresh trauma but leaves the body by its own forces to overcome the infection and to cast off the dead tissue

This takes time and as long as the basis of supply is left it is a perpetual source of danger Recognising this the tendency of surgery is now as we have indicated to remove the dead material by the knife—to excise the wound in other words But the exact amount of dead material cannot always be appraised with the naked eye and moreover the very act of excision inflicts a fresh trauma liable to become immediately re infected Further this is a gross and mutilating form of attack, and for anatomical reasons is not always possible A consideration of the pathological features of gunshot wounds has led Bashford practically to advocate immediate excision impressed as he is by the almost constant presence of anaerobic organisms in relation to the dead tissues Our whole knowledge of anaerobes however is imperfect and chaotic So many of them being practically saprophytes produce potent poisons as a result of their activity on dead tissue that all are indiscriminately condemned The organism which we describe here however is apparently one of the exceptions It is apparently non pathogenic does not produce toxins inimical to the human body and does not apparently attack living tissues At the same time however it appears to be able rapidly to break down dead tissue without in doing so producing toxins and this is proved amongst other things by the appearance of the shreds of slough remaining in the wound after removal of the salt bag These look thin, almost transparent, and generally wash away easily under slight irrigation

This organism can dissect away the macroscopic and microscopic dead tissue in a way that no surgeon's knife ever can, and that without at the same time producing any further trauma The devitalised tissues are practically all removed in a few days and with their destruction the breeding ground of the pathogenic germs is destroyed, while the living tissues relieved of the strain of ever combating the increasing infection while trying to cast off the devitalised tissue, is able to turn its energies to repair, as evidenced by the rapid formation of healthy, strong granulations

DESCRIPTION OF METHOD OF TREATMENT

We should like to emphasise again the extreme importance of the presence of devitalised tissue in a wound, and no wound can be inflicted without a certain amount of devitalisation whether microscopic or macroscopic

There are certain points, however to which it is necessary to draw attention in the treatment of these wounds, and they are points which must be borne in mind

The most important and fundamental is the need to lay open a wound in the most thorough manner possible It is a point that is not always carried out, but it is essential Whether obviously dead tissue is cut away or not at the same time is, with the method of treatment we advocate, not absolutely necessary, but it is all important to lay open every pocket so that the packing will be in contact everywhere with the walls of the wound As the wounds are so often irregular and burrowing, this will call for the ingenuity of the surgeon in each case All foreign bodies must likewise be removed and any grossly damaged tissue may at the same time be removed

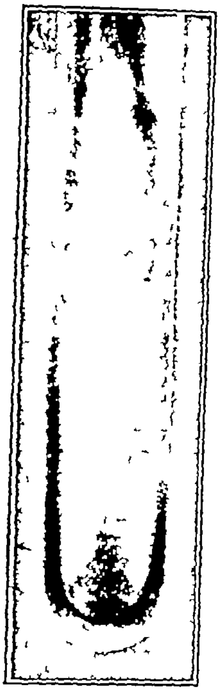
The interior of the wound is now irrigated with sterile water or saline to wash away obvious pus or blood, and the living culture of the organism is now sown in the wound Hitherto we have used a pipette for the purpose Immediately thereafter the packs, whether of salt or of sphagnum moss are introduced into the wound so as to come in contact with every part of it Just before introduction the packs are moistened with sterile water or saline Over this several layers of plain gauze are laid after slightly soaking in the same way The wound is thus completely and firmly packed and over-all a thick layer of cotton wool, after which the whole is firmly bandaged It is an additional help to steady the limb by means of a splint The packing itself however acts as a splint as we shall see in the sequel Where salt has been used the patient has some slight pain for a few hours and whatever pack has been used the temperature will probably rise even higher than it was before interference with the wound

For the first 24 hours if salt has been used, there is a very copious discharge of fluid doubtless due to the concentration of salt in the wound Thereafter the flow ceases presumably as a result of reduced salt concentration A certain amount of pus oozes away and towards the end of the second day or at latest the third day, the wound begins to smell in cases which have been unsown but where the organism has been present This corresponds more or less closely to what occurs *in vitro* A culture sown in meat broth from the sporing form does not begin to smell much till the end of the second or till the third day, and probably means the length of time needed for the spores present to germinate sufficiently for the proliferating organism to attack the dead tissue in sufficient numbers to be able to cause the smell At the same time, as has been noted by nearly all who have written on the salt-bag treatment the temperature begins to come down towards the end of the second or third day and thereafter as a rule stays down This seems to coincide with the production of the foul odour If in an unsown case where salt bags are used, by the third or at latest the fourth day the temperature shows no signs of subsiding and the wound does not emit the offensive stench it is not doing well and is not going to do well under that treatment and it is a signal for the sowing of the wound with the living organism Where on the other hand the characteristic smell is markedly present and yet there is no fall in the temperature look for some other focus of infection or some other wound perhaps slight and consequently treated by one of the old antiseptics

From the third day onward the patient steadily improves There is no daily dressing to worry him, except perhaps the

laying on of a fresh pad of cotton wool, he has no pain, and is able to eat and sleep well There is only one objectionable feature—viz., the foul odour, and that is the signal that all is going well The temperature is said, by most observers, to be no criterion so long as the pulse and the patient s general condition is good The temperature, however, is a valuable guide taken in conjunction with the presence or absence of odour

FIG 1



Agar slope culture some days old

Next comes the question of how long the pack is to be left in Further observation on this point is necessary, but probably seven days at least, although it will probably vary with the type of wound The packing is removed without an anæsthetic as a rule When one goes to remove it, the superficial part of the packing will be found more or less firmly adherent to the skin, and set hard like a board Exactly how this happens we do not propose to discuss here Suffice it to say that it has been observed by all who have written about this method

After detaching the board like upper dressing from the skin, the rest of the pack comes out easily and *en masse* bathed, as a rule, in bright-yellow pus, from which we can recover the organism

A few *more or less delicate* sloughs may still remain adherent, but on irrigating, they either become detached at once or do so a day or two later As the fluid pours over the surface they wave about like little fragments of transparent seaweed The fluid used is either warm normal saline or eusol The rest of the surface will be seen to be red and clean After 24 hours more, during which time plain gauze wrung out of saline has been placed in the wound, the exposed muscle will be a brilliant red, devoid of sloughs, and covered by firm, healthy granulations which bleed easily if touched All œdema has disappeared from the neighbourhood

DISCUSSION OF SOME POINTS OF INTEREST

Such a wound rapidly heals, can be skin grafted and brought together In any case, it has been noticed that such wounds result in a beautiful firm and more or less linear scar One other point remains to be mentioned—viz, that in no case where we have used salt bags has secondary hæmorrhage occurred This also coincides with the recorded observations of others Major A J Hull,[6] R A M O for instance, states that in his hands the salt-bag treatment has been one of the most generally applicable of procedures for the treatment of secondary hæmorrhage This, of course, is in direct opposition to the expressed statement of Sir Almroth Wright who says that the aim and object must be to prevent any digestive action in the neighbourhood of the endangered artery

Another point of interest is the appearance of sequestra. These appear, so far as our observation goes, to come away more rapidly than in cases not so treated and when they do come away they are white and clean and devoid of all soft tissue Further, where from anatomical reasons it is necessary to carry out manipulative procedure for the removal of the sequestra it has been observed that there is no post-operative flare up as there is in cases which have been treated *otherwise* Doubtless this is due to the fact that in the former case all the dead soft tissues have been thoroughly proteolysed, and the breeding ground in the bone for lurking pathogenic germs has been destroyed, whereas in the latter they are both present, and even slight manipulation *causes* a reinoculation of the patient and a consequent flare up

There are many other points which space forbids us to discuss, points observed and raised by others who have used used salt bags, but a consideration of the facts we put forward in this paper will probably explain away some of their difficulties, and we venture to hope furnish a true rationale of this simple method of treatment.

We propose, in the meantime, to christen the organis the Reading bacillus It certainly belongs to the proteolyt group, but in view of the somewhat chaotic state knowledge regarding the whole group of anaerobic spor bearers we are *not concerned* for the moment to identify with any previously described, though doubtless it has bee observed and described before, a very similar organis having been noted by Miss Robertson, for example, in wa wounds

The main thing to recognise is the possibility of turnin it to advantage and so using one type of germ to depriv the others of *their breeding ground* Doubtless, also, othe *organisms may* be turned to use, as some have already bee to commercial *purposes*

After the following brief account of the organism we shall append a brief description of a few cases from among many treated by the salt-bag method. They are chosen in order to illustrate points referred to in the paper, and at a later date we hope to be able *to correct where necessary* or to *amplify the statements* we have made Cultures of the organism will willingly be furnished on application to Dr Donaldson, Pathological Department, War Hospital Reading

We feel that the views here expressed and the proofs given will at once supply the key to much that has been obscure to those who have used the salt-pack method to any *extent* They are unanimous in stating that the superiority of the salt pack is an undoubted clinical fact, but why it should be so they admit they cannot explain

We are thoroughly alive to the fact that, while proteolysis of the dead tissue appears to be the fundamental principle involved, there may be other factors of a bio-chemical character at work as a result of this organism's activity, especially in view of the almost immediate and rapid improvement in the general condition of the patient Such, however will form a subject for further research. But there is some evidence for believing that the Reading bacillus is not without effect on the tox albumins produced by other organisms

FIG 2A

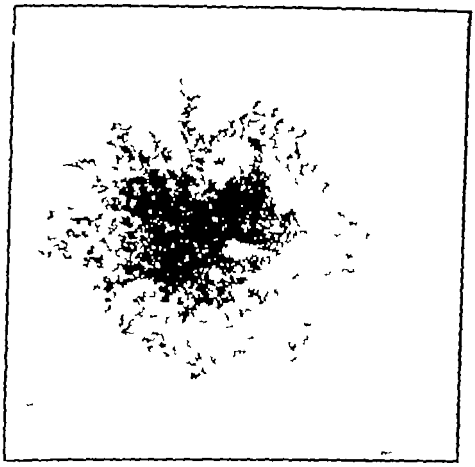


FIG 2B

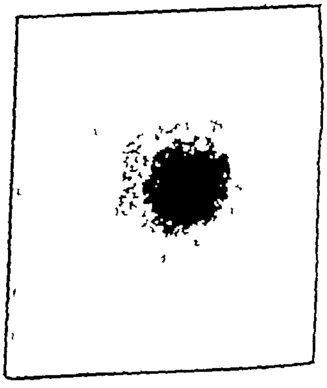
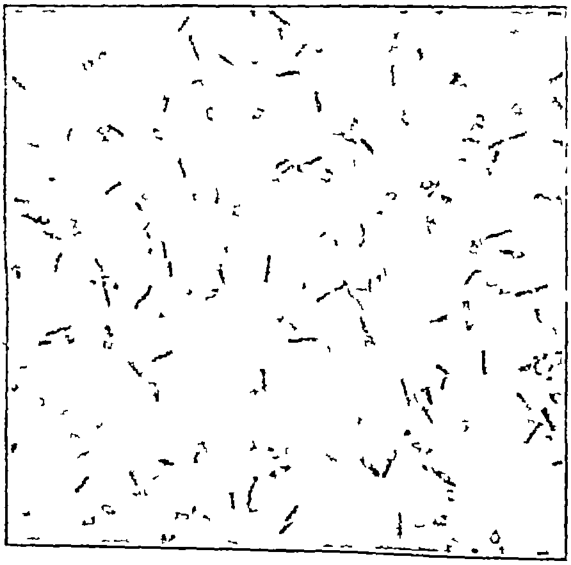


Colonies from an agar plate 18 days old × 10

CHARACTERS OF THE READING BACILLUS

The reasons for giving it this name provisionally have been indicated It appears to be a saprophyte and may be identical with what Miss Robertson has been able to isolate from wound infections, and which, according to her con forms in its morphological and cultural characters with the *B œdematis maligni* of Koch, as described by von Hibler Owing to the non pathogenicity of the Reading bacillus, we do not feel disposed in the meantime to follow Miss Robertson s lead with regard to its correct designation The fact of there being undoubted strains with morphological and cultural characters similar to those of the malignant œdema bacillus of Koch which are nevertheless non pathogenic even when freshly isolated from wound infections, while his bacillus is definitely pathogenic suggests that there is much yet to be done before a correct terminology is arrived at Space forbids the inclusion of any detailed description of the organism and no reference is made to work still in course of investigation The characters as given are based on a study of what we consider to be most likely a pure culture This culture was arrived at (after repeatedly plating out) by the dilution method already referred to and only then after the second attempt

FIG 3



The Reading bacillus grown for 48 hours in maltose broth Gram × 1000.

Morphology —The organism consists of a rod having a fairly large oval subterminal spore (Fig 3) The actual shape is probably best seen in hanging-drop preparations when the body of the bacillus appears to be somewhat torpedo-shaped The blunter and broader end corresponds to the situation of the contained spore and from this the body gradually narrows to the opposite extremity In dried films on the other hand the oval spore appears to bulge out on either side beyond the bacillary body but this is apparently an artefact In a few instances the spore is central while the bacillary body tapers away to either extremity and occasionally one or two can be seen where the oval spore is situated terminally The bacillus is provided with numerous long wavy lateral flagella which when seen detached closely resemble spirilla with regular undulations (Fig 4) Under certain conditions there may be found along with free bacilli chains composed of bacillary elements of varying size one or two of which may even show spore formation The chain form may be represented by an unsegmented filament In young cultures of course non-sporing bacilli predominate while in old cultures on solid media practically nothing remains but spores some of these still in chain formation with the suspicion of the outlines of a filament in which they have apparently been formed

Size —The average length of the sporing bacillus varies from 2 5 to 3μ with a breadth of 0·5 to 0·9μ, while free spores show an average of 1·45μ long by 1·02μ broad These figures refer to the organism in the dried film and of course there are other forms either larger or shorter

Motility —The organism both in its sporing and non sporing form is actively motile having a somewhat waddling movement and the power of motility apparently persists for a considerable length of time

Staining —It is Gram positive stains easily with the usual stains but is not acid fast

Range of growth —Its exact limits of growth or optimum temperature have not been determined but it will grow at 1[illegible]° C and probably also at 41 C although it appears to do best at body temperature It will [illegible] for long in the spore form which appears to be fairly resistant to heat It appears to be strictly anaerobic and has marked proteolytic properties.

[illegible] —All cultures emit a strong characteristic and somewhat fetid though not unbearable odour This is perhaps best observed in meat tubes and if the culture has been raised from spores does not become really strong till the end of the second or third day In about a week's time in such a tube the colour has [illegible]

Gas is also formed in greater or less degree according to the culture medium employed

In broth containing minced up bullock s heart slight blackening begins to appear towards the end of 48 hours where the culture has been raised from spores and is quite definite as a rule on the third day During the same time the volume of contained meat can be seen to be diminishing in volume and to be going into a state of finer subdivision This diminution gradually becomes more marked Gas can be seen on the second day in the form of a few bubbles caught between the fragments of meat but is given off in greater quantities on the third day The gas consists largely of CO_2 H_2S and ammonia The supernatant broth is turbid but in an old tube which has been standing for some time the turbidity deposits and the upper layers of fluid become fairly clear

On *agar* surface colonies are small about the size of small streptococcus colonies (Fig 1) They are slightly raised rounded shiny and translucent at first but later tend to become more opaque The edge is not sharply defined but merges into a radiating tangle of fine threadlike projections for the definition of which a hand lens is generally required In place of or along with these fine filaments may be seen sometimes somewhat broader outgrowths which look like transparent fimbriæ

If the water of condensation has become infected growth occurs fairly rapidly as a faint opalescent film spreading up between the tube and the medium with a growing edge which is often fimbriated The agar ultimately becomes cracked and split up by gas

Deep colonies can just be seen with the naked eye after 48 hours growth when their size resembles that of young streptococcus colonies They appear however slightly opaque depending on their depth in the medium and their size and have a dirty white colour With a hand lens the central part appears irregular in shape being oval triangular &c with rather blurred edges which merge into a tangled massed of filaments which are growing out from it into the medium. The resulting colony looks fluffy resembling a little speck of cotton wool embedded in the medium (Figs 2A and 2B) The best growth is apparently obtained in media to which glucose has been added

Gelatine is fairly rapidly liquefied the fluid becoming turbid

Inspissated serum is gradually eaten away the crumbling edges being slightly blackened

Dorset egg medium is more rapidly broken down preceding which there is a greyish black discolouration of the medium

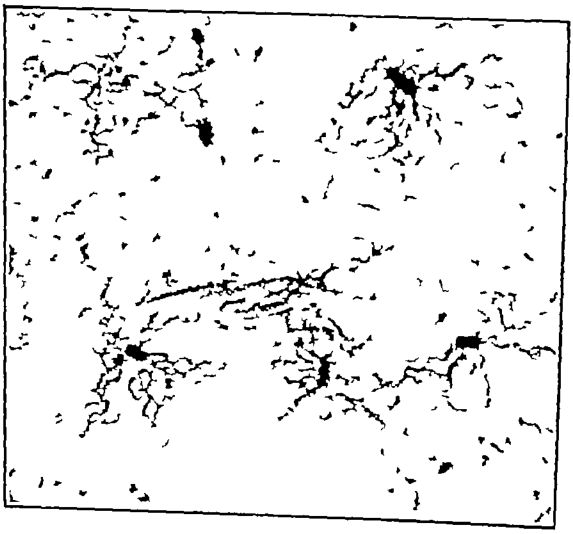
Broth becomes turbid with a greater or less fleecy deposit, according to the ingredients of the medium and there is a certain amount of gas generated. This is considerable in glucose and in glycerine broth but rather less in plain nutrient broth and only a very little in inulin broth The turbidity is greatest in glucose broth and least in glycerine On standing for some time the deposit tends to settle leaving the upper layers of fluid fairly clear except in the case of glucose broth

Potato —No growth visible to the naked eye has been observed even after some weeks of culture, but slight growth does take place

Litmus milk.—No clot is observed even after many days' incubation Instead the milk is broken down into fine granules and it becomes much less opaque and more watery After three days incubation it is apparently slightly acid and differs in this respect from the cultural characters of the organism described by Miss Robertson Gas is produced

Litmus peptone water is rendered turbid and definitely alkaline No indol appears to be formed

FIG 4



Reading bacillus showing flagella from a 24 hours agar slope × 1000

Fluid egg medium becomes more opaque a fairly heavy deposit settles and considerable gas is generated

Neutral-red broth —No change in colour is observed in strong dilutions The neutral red inhibits the growth of the organism and apparently kills it as subcultures made from various dilutions have failed to grow In higher dilutions however the colour is discharged and the fluid becomes markedly fluorescent

Other media.—In the case of the sugars glucosides &c., the reactions of the Reading bacillus have been observed in litmus peptone water and also on serum litmus agar each with its appropriate sugar The sugars unfortunately were not pre-war sugars and the peptone was Fairchild s Glucose maltose lævulose and dextrine are all turned acid while a considerable quantity of gas is generated The colour change is not of equal intensity in all four tubes Saccharose and sorbite are rendered a lilac tint the former having much less gas and only changing colour after several days incubation No acidity has been observed in mannite, lactose, raffinose, dulcite, inulin starch salicin or glycerine although there was a slight generation of gas in all except in the last where it was fairly considerable

Optimum reaction —This is probably about + 5 to phenolphthalein A good growth is also obtained in broth with a reaction of + 3 5 After 10 days incubation however growth also took place in broths with a reaction of + 16 75 + 10 5 and − 0 5 respectively The reactions were determined in uninoculated broths in the cold after final sterilisation.

Pathogenicity —Rabbits mice and guinea pigs have been inoculated intravenously intraperitoneally or subcutaneously into the muscles both with cultures grown on solid and in fluid media respectively The cultures were of various ages We do not propose to go into details of dosage &c. beyond stating that as many as 30 000 millions of living bacilli have been given to guinea pigs without death or any other disturbance taking place As noted in the text, it has been now sown in very liberal quantities both in recently incised as well as in septic wounds of varying age without any evidence of the slightest pathogenicity Further experimental work is in hand but it would be premature to mention this at present.

Record of Cases

We now append a few cases, chosen because they illustrate most of the points raised in the paper and because they bear out the statements made concerning the beneficial action of the bacillus and its non pathogenicity

CASE A.—Admitted with gunshot wound of left buttock and a smaller wound near right anterior inferior iliac spine containing a foreign body On arrival in Reading it was suppurating and had been plugged with gauze For the next 5 days there was an irregular temperature ranging from 99° to 104° F with pulse of 96 to 116 At the end of this period of 5 days the wounds were thoroughly laid open the foreign body removed and salt bags inserted

The temperature, however did not fall and it was noted that the characteristic salt-bag odour was absent. The bags were left *in situ* for 6 days and as there was no improvement, they were removed, and eusol dressings substituted It was noted on removal that the wound was œdematous and unhealthy and that no separation of the sloughs had occurred Eusol dressings were persisted in for the next 21 days before the wound could be pronounced clean and healthy although the temperature came down after 4 days of eusol treatment and remained down with the exception of 9 days during which it fluctuated between 100° and normal

This is an example of a wound packed with salt bags which did not smell and which took 40 days from receipt of injury to reach a point when it could be considered a healthy granulating surface.

CASE B —Admitted at Reading 10 days after receipt of gunshot wound of right knee involving the joint. The wound was very sloughy thoroughly exposed and the patella had evidently been removed *Six days later the limb above and below the joint appeared* very œdematous and a considerable amount of pus could be expressed from under the skin on the inner side of the joint. Two days later this sinus was laid freely open Five days thereafter the œdema of leg and thigh was more pronounced and the patient appeared hectic The wound was at once thoroughly opened up again multiple superficial incisions made in the neighbourhood and the whole well packed with salt bags

Five days later there was no evidence of characteristic odour from the dressings the temperature still continued to jump and the man was evidently going down hill The following day after consultation, amputation was performed through the thigh Four days later the patient died.

This is another example of free exposure of the wound and subsequent packing with salt bags No improvement whatever took place no salt-bag odour was detected and the man died apparently of septicæmia

CASE C —Admitted at Reading with gunshot wound of right leg together with a compound fracture of the femur received about 3 months previously The history was as follows The patient lay out in the open for 4 days before being brought in and he remained at the C C S for 11 days during which time gas gangrene developed and the patient became very ill He was removed to a base hospital where the wounds were explored and drained (No notes available of the wound dressings at that time) Later a sequestrum was removed. The wound was then packed with salt bags but for some reason these were removed the following day his temperature being 102 4° F and his pulse 138 The wound was then syringed with H_2O_2 His condition still remained bad He was then transferred to England

For the first few days after admission to Reading he appeared to make satisfactory progress Then swelling and œdema of the thigh and rise of temperature made themselves apparent and 7 days later the wounds were freely opened up and the bone drilled The latter was soft and infiltrated with inflammatory products but no free pus was discovered The wounds were then packed with salt bags Two days thereafter the wound emitted a powerful and characteristic odour and the edges looked dirty and sloughy Cultures were made and the Reading bacillus isolated together with pyogenic organisms Six days after packing the salt bags were removed and the patient s condition was excellent Three days later after normal saline dressing the wound was reported to be clean and lined with healthy red granulations A few days later a small sequestrum came away in the dressings and in 6 weeks time from the introduction of the salt bags the wound was completely healed.

This case illustrates several points The patient had suffered considerably from exposure before treatment and had developed gas gangrene Salt bags had been applied abroad but were not persevered with beyond one day On reaching Reading salt packs were again introduced and kept in The temperature fell the following day and remained normal The wound gave out the characteristic smell and the Reading bacillus was isolated from the discharges

CASE D —Admitted with accidental gunshot wounds of left thigh testicle and right arm received the same day several foreign bodies being present in the wound There was an entrance wound just below fold of left buttock and a large explosive exit wound in the upper third of left thigh a wound of the left side of scrotum and a transverse wound on the flexor aspect of right wrist In the region of the thigh wound there was much destruction of muscle tissue. The femoral artery was exposed and lying bare on the outer side of the wound A piece of the tuber ischii had been chipped off and a channel passed up into the pelvis.

Lister s technique was used for disinfecting the skin the wound was irrigated with 1 in 3000 biniodide and salt bags were introduced. The testicle was removed and the wound on the wrist stitched up

Four days later the salt bags were removed as the temperature was rising and the edges of the wound looked black sloughy and semi digested The odour was intense but characteristic. There was no swelling or œdema anywhere near the wound *Cultures made from the* pus showed the presence of the Reading bacillus Eusol irrigation was substituted for the salt bags and next day it was noted that the dead muscle was coming away freely in fairly large quantity The wound still had a greyish black appearance and still smelt. The temperature however, had not come down and on further investigation it was found that the right hand was swollen and œdematous The stitches were removed from the wrist wound and a considerable quantity of pus escaped

Three days after removal of salt bags the wound in the thigh was found lined with healthy red granulations with a few specks of sloughy material on the surface and a larger one on the outer side of the wound There was some brown foul smelling pus in the wound but no surrounding œdema or erythema. Eight days after removal of the salt packs the wound presented a brilliant red colour and looked like a text-book illustration of a dissection of Scarpa s triangle. The temperature did not come down till the wrist, which had *not* been treated with salt packs had improved

This case also affords some points of interest. First it was a gunshot wound seen immediately after infliction and there was much destruction of muscle tissue The Reading bacillus was present as presumed from the almost overwhelming odour and as proved by culture The salt packs however were removed as the temperature was going up This on further consideration was a mistake The rise of temperature was in reality due to the progressive infection of the wrist wound The much larger wounds in thigh and buttock while *looking sloughy and black presented no signs of* acute infection The sloughs separated rapidly but probably not so quickly as they would have done if the salt bags had been left a day or two longer The devitalised tissues were obviously in process of digestion and indeed, granulations had already begun to form This wound was in a healing condition before the wrist wound untreated with salt packs had begun to clear up

CASE E —Admitted at Reading with gunshot wound of left thigh and leg received about two months previously The history before arrival in England was as follows There had been a very severe gaseous cellulitis of the leg and a less severe one of the thigh Carrel Dakin treatment had been used throughout. He had already been in the operating theatre *on 25 occasions for various* operative measures before reaching England On arrival here the limb was still very œdematous the four leg wounds looked unhealthy the granulations were sodden and œdematous and tunnels ran in *through them to the bone* these tunnels being occupied with Carrel Dakin tubes The wound in the thigh was similar to that in the leg and was discharging much pus

All 5 wounds were laid freely open deep collections of pus evacuated from each and small sequestra removed All were then dried with plain gauze and sown copiously with a living culture of the Reading bacillus Each one was firmly packed with salt bags moistened in normal saline and layers of gauze similarly moistened were laid across the wounds The temperature rose after the packing as it does in most cases but the patient was comfortable. On the second day after packing the œdema was seen to have diminished

The salt bags were left *in situ* for 9 days and on removal of the bags the characteristic odour made its presence strongly felt. The superficial gauze was seen to be dry brown board like and firmly adherent to the skin all round the wounds The odour was quite characteristic On loosening the adherent edges the whole packing came out *en bloc* bathed in yellow pus

The thigh wound was then irrigated with eusol after which it was seen to be perfectly clean and red. The fragment of exposed bone could be seen *in situ* looking white and clean All œdema had disappeared from the tissues around

The wounds in the leg showed much the same appearance, but there were still present in them a few very delicate thin sloughs which looked as if they were nearly digested while bright-red easily bleeding granulations could be seen all round All œdema had disappeared from the ankle and foot and had almost disappeared from the leg The wounds were simply irrigated with eusol and dressed with plain gauze daily and are now healing up

This case again is of interest, as it was one of severe multiple wounds with comminuted fractures of femur and leg bones which had become infected with a gas producing bacillus. He had been under Carrel Dakin treatment for two months and had had 25 operations of one sort or another performed In spite of this the wounds were unhealthy full of pus and the limb œdematous on arrival in Reading No risks were taken and the Reading bacillus was at once sown and salt packing applied without any other operative procedure whatever beyond reopening the wounds more freely evacuating pus and swabbing up with dry gauze Within ten days from the commencement of the treatment the wounds were healthy lined by strong granulations and all œdema had gone The Reading bacillus was recovered from the wound when the salt packs were removed

CASE F —Admitted at Reading 17 days after receipt of gunshot wounds of left leg and chest There were two clean wounds above the left ankle together with a fracture of the fibula There was another situated on the posterior aspect and several more on the leg and thigh as well as three clean wounds of left side of chest and a small hole on the front of the right thigh discharging pus Nine days later it was noted that the wound above the right ankle was suppurating and two days after that, as the patient s temperature continued to show a daily rise an abscess was evacuated from the region of the left ankle together with a foreign body The wound being thus laid freely open was then packed with salt bags

These bags were left *in situ* for six days without interference mean while no odour was perceptible and the temperature showed even greater daily fluctuations than before The bags were accordingly removed and it was seen that there were considerable swelling and œdema of the foot and ankle Cultures were made from the pus but we failed to isolate the Reading bacillus The following day the wound was reopened pus evacuated and the cavity dried out with sterile gauze The wound was then liberally sown with a living culture of the Reading bacillus and immediately packed with bags of sphagnum moss moistened with sterile water

The following day the patient stated that the ankle was more comfortable than it had been since he was wounded The temperature fell considerably on the third day and on the seventh day after moss packing it came down for good The moss was left *in situ* for six days, during which time the characteristic odour was very perceptible From cultures taken on removal of the bags the Reading bacillus was recovered

The superficial gauze and layers of the sphagnum moss bags had set quite hard and board like as in the case of the salt bags The wounds were covered with a greyish yellow purulent discharge but on irrigation with eusol they were found to be lined with perfectly healthy red granulations All swelling of the foot and ankle had disappeared

This case illustrates that free opening of the wound evacuating of pus and plugging with salt bags is not necessarily followed by improvement In connexion with this are to be taken the facts that the characteristic smell was absent and that we failed to prove the presence of the Reading bacillus At the second operation the Reading bacillus was introduced in living culture and to eliminate any action by salt an inert substance sphagnum moss was used for packing The wound at once began to do well and in six days was a granulating healthy surface The characteristic odour was present and the organism was recovered It is to be noted that while the sphagnum moss bags were hard and board like on removal exactly as is observed with salt packs the initial copious flow of fluid which always occurs during the first 24 hours after the introduction of salt bags was absent. The effect of the concentrated salt where salt bags are used is probably solely a hydragogic one, since both are equally hard and dry on removal suggesting a more or less impermeable layer of albuminous matter while inside there is a copious supply of fluid pus

CASE G —Admitted at Reading with gunshot wounds of left foot and right leg received eight days previously On arrival it was found that pieces of shrapnel had been removed from both wounds There was a small suppurating wound on the inner side of the left foot just above the base of the first metatarsal bone The outer side of the foot was œdematous There were also through and through wounds about two inches apart over middle of fibula

Three days later the wound in the foot was opened up for the purpose of extracting a foreign body and the cavity was then packed with Morison s B I P P Nine days thereafter he was sent to an auxiliary hospital Nine days after that a small piece of bone came away from the foot Five days thereafter the patient complained of severe pain in the foot with a temperature of 100° F Fomentations were applied but it became more swollen and painful and two days later the foot was incised on the inner side The outer side of the foot was discharging pus freely The temperature was now 101 4° Saline baths and fomentations were applied Seven days later as the temperature refused to come down the patient was anæsthetised and several pieces of the scaphoid were removed Incisions were made in many places pus evacuated and drainage tubes inserted

Next day the foot was still greatly swollen but there was very little free discharge and the temperature was still up Three days later as no satisfactory progress was being made the patient was sent back to the central hospital for further treatment or amputation On arrival in Reading the patient was again anæsthetised and after taking samples of the pus for cultural purposes multiple incisions were made into the foot and the mid tarsal joint was found to be infected The wounds were then irrigated with hot normal saline and both the old wounds and the freshly made incisions were sown with a living culture of the Reading bacillus The wounds were then packed with salt bags The cultures made from the pus yielded a copious growth of *Streptococcus longus*, together with a few colonies of *Staphylococcus aureus*

The temperature immediately began to fall and the œdema to diminish while the characteristic odour made itself evident The salt bags were removed in five days time and the wound irrigated with normal saline. They were lined with a sero-purulent exudation and there were present some dirty sloughs, which cleaned up at once under irrigation Cultures were made from the wounds and streptococci staphylococci and the Reading bacillus were isolated Three days later under simple normal saline dressings, the sloughs were found to be fast disappearing and the wounds were rapidly cleaning up Cultures made at this point yielded only staphylococci and the Reading bacillus Three days later the wounds were perfectly clean and lined by firm red, healthy granulations Cultures made showed only a few colonies of staphylococci and diphtheroids but the Reading bacillus was not again recovered. In about six weeks from the date of removal of the salt bags all the wounds in the foot were healed The movements of the foot were much improved and there was considerably less talipes equinovarus.

This patient appeared to be doing fairly well after the B I P P treatment There was however apparently a latent infection still present in spite of the B I P P treatment which flared up later In spite of multiple incisions saline baths and saline dressings the foot went from bad to worse The patient was extremely ill the foot greatly swollen and bright red due to the streptococcal infection and the discharge was scanty The joint was found to be involved The Reading bacillus together with salt packing at once altered the patient s condition and his foot made an uninterrupted recovery It is further to be noted that even after five days of salt-bag treatment streptococci were still present showing how much value to lay on the supposed bactericidal properties of the salt pack The B I P P treatment in this case had not been a success

In conclusion our thanks are due to the sisters and nurses for their intelligent coöperation in the clinical side of the work, and to Miss Clark B Sc to Mr R C McLean, D Sc., and to Mr Lamb for their active and ungrudging assistance in the scientific part of the investigation

Summary

1 Three main methods of wound treatment are at present in vogue the antiseptic, the physiological, and the surgical, viz , by excision of the wound The last-named has come into vogue because of the disappointing results obtained from the first two, on the score of their inefficacy or because of the time element

2 From the physiological or hypertonic saline method has evolved as an offshoot the salt-pack treatment of wounds for which its advocates claim extraordinarily good results

3 These include the simplicity of method, the avoidance of daily dressing of the patient, the rapidity with which the wound becomes a healthy granulating surface, the absence of secondary hæmorrhage, and the rapid general improvement of the patient All this means a considerable curtailment of the time spent by the wounded man in hospital

4 Hitherto the good results have been attributed in some obscure way to the presence of the salt acting more or less on the physiological lines described by Wright , but it is felt by all who have written about salt packs that some other explanation is necessary

5 We afford what we believe to be the true explanation of the phenomena observed, and believe that it will clear up many of the points that have hitherto been obscure

6 The key to the situation depends on two observations—one clinical the other bacteriological The former consists in the fact that cases which smell (and the odour is one of the most characteristic features of these cases) do well, while those which do not make no headway The bacteriological observation consists in the discovery that a certain bacillus is apparently constant in the wounds which emit the odour, while it is absent or cannot be recovered from those which do not smell

7 This bacillus is a spore-bearing anaerobe of a saprophytic nature and belongs to the proteolytic group of organisms—the group which includes *B tetani* and *B œdematis maligni*

8 Unlike these latter, it appears to be non pathogenic to the animals experimented on, and what is of more importance, appears to be non pathogenic for man when introduced into wounds Further unlike the above-named pathogenic varieties, it does not appear to set free any toxins injurious to the patient in the course of its action on the dead tissues

9 A brief outline of the morphological and cultural characters of the organism is given its probable mode of action and the results of animal experiment

10 While it may be one that has been fully described before, we make no attempt in this paper to identify it with such in view of the somewhat chaotic state of our knowledge regarding anaerobes Hence, for convenience sake, we call it the *Reading bacillus*

11 It acts, apparently in virtue of its proteolytic powers only on devitalised tissue, and possibly on tox albumins, and appears to possess no power of attacking healthy structures

12 Special stress is laid on the necessity of recognising the fact that one of the chief factors which keep a wound septic is the presence of devitalised tissue in that wound This acts as a base from which pathogenic organisms attack the body We would lay even greater stress on this than on the infecting organisms

13 The surgical or excision treatment of wounds apparently recognises this but only aims at removing macroscopically devitalised tissues, and in doing so inflicts a fresh trauma liable to reinfection

14 For this we propose to substitute the Reading bacillus in a living form and it is probably present in most of the wounds if only given a chance to carry on its functions These are directed towards the removal not only of the grossly damaged tissue, but it succeeds also in attacking the microscopically damaged structures As a result the body forces are freed from the constant menace of septic poisoning, thus allowing them to begin the work of repair

15 We give examples of gunshot wound cases which have been treated in various ways previously, including the salt-bag method, but without success These however, on being sown later with living cultures of the bacillus, have immediately started to do well and have ended in rapid recovery

16 The organism is probably present in the larger number of infected wounds but requires more or less anaerobic conditions before it can come into play

17 These are provided by the pack method of treatment, but we are inclined to think that salt is not a necessary adjuvant

considerable quantity of gas is generated The colour change is not of equal intensity in all four tubes Saccharose and sorbite are rendered a lilac tint the former having much less gas and only changing colour after several days incubation No acidity has been observed in mannite lactose raffinose dulcite, inulin starch salicin or glycerine although there was a slight generation of gas in all except in the last where it was fairly considerable

Optimum reaction —This is probably about + 5 to phenolphthalein A good growth is also obtained in broth with a reaction of + 3 5 After 10 days incubation however, growth also took place in broths with a reaction of + 16 75 + 10 5 and − 0 5 *respectively The reactions* were determined in uninoculated broths in the cold after final sterilisation

Pathogenicity —Rabbits mice, and guinea pigs have been inoculated intravenously intraperitoneally or subcutaneously into the muscles both with cultures grown on solid and in fluid media respectively The cultures were of various ages We do not propose to go into details of *dosage &c beyond stating that as many as 30 000* millions of living bacilli have been given to guinea pigs without death or any other disturbance taking place As noted in the text, it *has been now sown* in very liberal quantities both in recently incised as well as in septic wounds of varying age without any evidence of the slightest pathogenicity Further experimental work is in hand but it would be premature to mention this at present

RECORD OF CASES

We now append a few cases, chosen because *they* illustrate most of the *points raised* in the *paper* and *because they* bear out the statements made concerning the beneficial action of the bacillus and its non pathogenicity

CASE A —Admitted with gunshot wound of left buttock and a smaller wound near right anterior inferior iliac spine containing a foreign body On arrival in Reading it was suppurating and had been plugged with gauze For the next 5 days there was an irregular temperature ranging from 99° to 104° F with pulse of 96 to 116 At the end *of this period of 5 days* the wounds were thoroughly laid open the foreign body removed and salt bags inserted

The temperature, however, did not fall and it was noted that the characteristic salt-bag odour was absent. The bags were left *in situ* for 6 days and as there was no improvement they were removed and eusol dressings substituted It was noted on removal that the wound was œdematous and unhealthy and that no separation of the sloughs had occurred Eusol dressings were persisted in for the next 21 days before the wound could be pronounced clean and healthy although the *temperature came down after 4 days of eusol treatment, and remained* down with the exception of 9 days during which it fluctuated between 100° and normal

This is an example of a wound packed with salt bags which did not smell and which took 40 days from receipt of injury to reach a point when it could be considered a healthy granulating surface

CASE B —Admitted at Reading 10 days after receipt of gunshot wound of right knee involving the joint The wound was very sloughy thoroughly exposed and the patella had evidently been removed Six days later the limb above and *below the joint* appeared very œdematous and a considerable amount of pus could be expressed *from under the skin on the inner side of the joint Two days* later this sinus was laid freely open Five days thereafter the œdema of leg and thigh was more pronounced and the patient appeared hectic The wound was at once thoroughly opened up again multiple superficial incisions made in the neighbourhood and the whole well packed with salt bags

Five days later there was no evidence of characteristic odour from the dressings *the temperature still continued to jump* and the man was evidently going down hill The following day after consultation amputation was performed through the thigh Four days later the patient died.

This is another example of free exposure of the wound and subsequent packing with salt bags No improvement whatever took place no salt-bag odour was detected, and the man died apparently of septicæmia.

CASE C —Admitted at Reading with gunshot wound of right leg together with a compound fracture of the *femur received* about 3 months previously The history was as follows The patient lay out *in the open for* 4 *days before* being brought in and he remained at the *C C S* for 11 days during which time gas gangrene developed and the patient became very ill He was removed to a base hospital where the wounds were explored and drained (No notes available *of the* wound dressings at that time) Later a sequestrum was removed The wound was then packed with salt bags but *for some reason these were removed the following day his temperature* being 102 4° F and his *pulse 138 The wound* was then syringed with H_2O_2 His condition still remained bad He was then transferred to England

For the first few days after admission to Reading he appeared to make satisfactory progress Then swelling and œdema of the thigh and rise of temperature made themselves apparent, and 7 days later the wounds were freely opened up and the bone drilled *The latter* was soft and infiltrated with inflammatory products but no free pus was *discovered The wounds were then* packed with salt bags Two days thereafter the wound emitted a powerful and characteristic odour and the edges looked dirty and sloughy Cultures were made and the Reading bacillus isolated together with pyogenic organisms *Six days* after packing the salt bags were removed and the patient s condition was excellent. Three days later after normal saline dressing the wound was reported to be clean and lined with healthy red granulations *A few days later a small* sequestrum came away in the dressings and in 6 weeks time from the introduction of the salt bags the wound was completely healed

This case illustrates several points The patient had suffered considerably from exposure before treatment and had developed gas gangrene *Salt bags had been applied abroad* but *were* not *persevered* with beyond one day On reaching Reading salt packs were again *introduced and kept in* The temperature fell the following day and remained normal The wound gave out the characteristic smell and the Reading bacillus was isolated from the discharges

CASE D —Admitted with accidental gunshot wounds of left thigh testicle, and right arm received the same day, several *foreign* bodies being present in the wound. There was an entrance wound just below fold of left buttock and a large explosive exit wound in the upper third of left thigh a wound of the left side of scrotum and a transverse wound on the flexor aspect *of right wrist* In the region of the thigh wound there was much *destruction of muscle tissue* The femoral artery was exposed and lying bare on the *outer side of the wound* A piece of the tuber ischii had been chipped off and a channel passed up into the pelvis

Lister's technique was used for disinfecting the skin the wound was irrigated with 1 in 3000 biniodide, and salt bags were introduced. The *testicle* was removed and the wound on the wrist stitched up

Four days later the salt bags were removed as the temperature was rising and the edges of the *wound looked black sloughy* and semi digested The odour was intense but characteristic There was no swelling or œdema anywhere near the wound Cultures *made from the* pus showed the presence of the Reading bacillus Eusol irrigation was substituted for the salt bags and next day it was noted that the dead muscle was coming away freely in fairly large quantity The wound still had a greyish black appearance and still smelt. The temperature *however had not come down and on further* investigation it was found that the right hand was swollen and œdematous The stitches were removed from the wrist wound and a considerable quantity of pus escaped

Three days after removal of salt bags the wound in the thigh was found lined with healthy red granulations with a few specks of sloughy material on the surface and a larger one on the outer side of the wound There was some brown foul-smelling pus in the wound but no surrounding œdema or erythema Eight days after removal of the salt packs *the wound presented* a brilliant red colour and looked like a text-book illustration of a dissection of Scarpa s triangle The temperature did not come down till the wrist which had *not* been treated with salt packs had improved.

This case also affords some points of interest. First it was a gunshot wound seen immediately after infliction and there was much destruction of muscle tissue The Reading bacillus was present as presumed *from the almost overwhelming odour and as proved by culture.* The salt packs however were removed as the temperature was going up This on further consideration was a mistake The rise of temperature was in reality due to the progressive *infection* of the wrist wound The much larger wounds in thigh and buttock, while looking sloughy and black presented no signs of acute infection The sloughs separated rapidly but probably not so quickly as they would have done if the salt bags had been left a *day or* two longer The *devitalised tissues were obviously in process of digestion, and* indeed *granulations* had *already begun to form* This wound was in a healing condition before the wrist wound untreated with salt packs had begun to clear up

CASE E —Admitted at Reading with gunshot wound of left thigh and leg received about *two months previously The history before arrival* in England was as follows There had been a very severe gaseous *cellulitis of the leg and a less severe one of* the thigh Carrel Dakin treatment had been used throughout. He had already been in the operating theatre *on* 25 occasions for various operative measures before reaching England. On arrival here the limb was *still* very œdematous the four leg wounds looked unhealthy the granulations were sodden and œdematous and tunnels ran in through *them to the bone* these tunnels being occupied with Carrel Dakin tubes. The wound in the thigh was similar *to* that in the leg and was discharging much pus

All 5 wounds were laid freely open deep collections of pus evacuated from each and small sequestra removed. All were then dried with plain gauze and sown copiously with a living culture of *the Reading* bacillus Each one was firmly packed with salt bags moistened in normal saline and layers of gauze *similarly moistened were* laid across the wounds The temperature rose after the packing as it does in most cases *but* the patient was comfortable. *On the* second day after packing the œdema was seen *to* have diminished

The salt bags were left in situ for 9 days and on removal of the bags the characteristic odour made its presence *strongly* felt. The superficial gauze was seen to be dry brown, board like and firmly adherent to the skin all round the wounds The odour was *quite characteristic* On loosening the adherent edges the whole packing came out *en bloc* bathed in yellow pus

The thigh wound was then irrigated with eusol after which it was *seen to be perfectly clean* and red. The fragment of exposed bone could be seen *in situ* looking white and clean All œdema had disappeared from the tissues around

The wounds in the leg showed much the same appearance, but there were still present in them a few very delicate thin sloughs which looked as if they were nearly digested while bright red easily bleeding granulations could be seen all round All œdema had disappeared from *ankle and foot* and had *almost* disappeared *from* the leg The wounds were simply irrigated with eusol and dressed with plain gauze daily and are now healing up

This case again is of interest as it was *one of* severe multiple wounds with comminuted *fractures of femur* and leg bones which had become *infected* with a *gas-producing* bacillus He had been under Carrel Dakin treatment *for two months* and had had 25 operations *of one sort or another performed In spite of this* the wounds were unhealthy full of pus and the limb œdematous on arrival in *Reading No risks* were taken and the Reading bacillus was at once sown and salt packing applied without any other operative procedure whatever beyond reopening the wounds more freely evacuating pus and swabbing up with *dry* gauze Within ten days *from the commencement* of the treatment the wounds were healthy lined by strong granulations and all œdema had *gone* The Reading bacillus was recovered from the wound when the salt packs were removed

CASE F —Admitted at Reading *17 days* after receipt *of* gunshot wounds of left leg and chest There were two clean wounds above the left ankle *together with a fracture* of the fibula There was another situated on the posterior aspect and several more on the leg and thigh *as well as* three clean wounds of left side of chest and a small hole on the front of the right thigh discharging pus *Nine days* later it was noted that the wound above the right ankle was suppurating and two days after that, as the patient s temperature continued *to* show a daily rise an abscess was evacuated from the region of the left ankle *together with a foreign body* The wound being thus laid freely open was then packed with salt bags.

These bags were left *in situ* for six days without interference meanwhile no odour was perceptible and the temperature showed even greater daily fluctuations than before The bags were accordingly removed and it was seen that there were considerable swelling and œdema of the foot and ankle Cultures were made from the pus, but we failed to isolate the Reading bacillus The following day the wound was reopened pus evacuated and the cavity dried out with sterile gauze The wound was then liberally sown with a living culture of the Reading bacillus and immediately packed with bags of sphagnum moss moistened with sterile water

The following day the patient stated that the ankle was more comfortable than it had been since he was wounded The temperature fell considerably on the third day and on the seventh day after moss packing it came down for good The moss was left *in situ* for six days during which time the characteristic odour was very perceptible From cultures taken on removal of the bags the Reading bacillus was recovered

The superficial gauze and layers of the sphagnum moss bags had set quite hard and board like as in the case of the salt bags The wounds were covered with a greyish yellow purulent discharge but on irrigation with eusol they were found to be lined with perfectly healthy red granulations All swelling of the foot and ankle had disappeared.

This case illustrates that free opening of the wound evacuating of pus and plugging with salt bags is not necessarily followed by improvement In connexion with this are to be taken the facts that the characteristic smell was absent and that we failed to prove the presence of the Reading bacillus. At the second operation the Reading bacillus was introduced in living culture and to eliminate any action by salt an inert substance sphagnum moss was used for packing The wound at once began to do well and in six days was a granulating healthy surface The characteristic odour was present and the organism was recovered It is to be noted that while the sphagnum-moss bags were hard and board like on removal exactly as is observed with salt packs the initial copious flow of fluid which always occurs during the first 24 hours after the introduction of salt bags was absent The effect of the concentrated salt where salt bags are used is probably solely a hydragogic one since both are equally hard and dry on removal suggesting a more or less impermeable layer of albuminous matter while inside there is a copious supply of fluid pus

CASE G —Admitted at Reading with gunshot wounds of left foot and right leg received eight days previously On arrival it was found that pieces of shrapnel had been removed from both wounds There was a small suppurating wound on the inner side of the left foot just above the base of the first metatarsal bone The outer side of the foot was œdematous There were also through and through wounds about two inches apart over middle of fibula.

Three days later the wound in the foot was opened up for the purpose of extracting a foreign body and the cavity was then packed with Morison's B I.P P Nine days thereafter he was sent to an auxiliary hospital. Nine days after that a small piece of bone came away from the foot Five days thereafter the patient complained of severe pain in the foot with a temperature of 100° F Fomentations were applied but it became more swollen and painful and two days later the foot was incised on the inner side The outer side of the foot was discharging pus freely The temperature was now 101·° Saline baths and fomentations were applied. Seven days later as the temperature refused to come down the patient was anæsthetised and several pieces of the scaphoid were removed Incisions were made in many places pus evacuated and drainage tubes inserted

Next day the foot was still greatly swollen, but there was very little free discharge and the temperature was still up Three days later as no satisfactory progress was being made the patient was sent back to the central hospital for further treatment or amputation. On arrival in Reading the patient was again anæsthetised and after taking samples of the pus for cultural purposes multiple incisions were made into the foot and the mid tarsal joint was found to be infected The wounds were then irrigated with hot normal saline and both the old wounds and the freshly made incisions were sown with a living culture of the Reading bacillus The wounds were then packed with salt bags The cultures made from the pus yielded a copious growth of *Streptococcus longus* together with a few colonies of *Staphylococcus aureus*

The temperature immediately began to fall and the œdema to diminish while the characteristic odour made itself evident The salt bags were removed in five days time and the wound irrigated with normal saline. They were lined with a sero-purulent exudation and there were present some dirty sloughs, which cleaned up at once under irrigation Cultures were made from the wounds and streptococci staphylococci and the Reading bacillus were isolated Three days later under simple normal saline dressings, the sloughs were found to be fast disappearing and the wounds were rapidly cleaning up Cultures made at this point yielded only staphylococci and the Reading bacillus. Three days later the wounds were perfectly clean and lined by firm red healthy granulations Cultures made showed only a few colonies of staphylococci and diphtheroids, but the Reading bacillus was not again recovered. In about six weeks from the date of removal of the salt bags all the wounds in the foot were healed. The movements of the foot were much improved and there was considerably less talipes equinovarus.

This patient appeared to be doing fairly well after the B I P P treatment There was, however apparently a latent infection still present in spite of the B I P.P treatment which flared up later In spite of multiple incisions saline baths and saline dressings the foot went from bad to worse The patient was extremely ill the foot greatly swollen and bright red due to the streptococcal infection and the discharge was scanty The joint was found to be involved. The Reading bacillus together with salt packing at once altered the patient's condition, and his foot made an uninterrupted recovery It is further to be noted that even after five days of salt bag treatment streptococci were still present showing how much value to lay on the supposed bactericidal properties of the salt pack The B I P.P treatment in this case had not been a success

In conclusion, our thanks are due to the sisters and nurses for their intelligent coöperation in the clinical side of the work, and to Miss Clark, B Sc. to Mr R. C McLean D Sc., and to Mr Lamb for their active and ungrudging assistance in the scientific part of the investigation

Summary

1 Three main methods of wound treatment are at present in vogue the antiseptic, the physiological, and the surgical, viz , by excision of the wound The last-named has come into vogue because of the disappointing results obtained from the first two, on the score of their inefficacy or because of the time element

2 From the physiological or hypertonic saline method has evolved as an offshoot the salt-pack treatment of wounds for which its advocates claim extraordinarily good results

3 These include the simplicity of method, the avoidance of daily dressing of the patient the rapidity with which the wound becomes a healthy granulating surface the absence of secondary hæmorrhage, and the rapid general improvement of the patient All this means a considerable curtailment of the time spent by the wounded man in hospital

4 Hitherto the good results have been attributed in some obscure way to the presence of the salt acting more or less on the physiological lines described by Wright , but it is felt by all who have written about salt packs that some other explanation is necessary

5 We afford what we believe to be the true explanation of the phenomena observed and believe that it will clear up many of the points that have hitherto been obscure

6 The key to the situation depends on two observations—one clinical the other bacteriological The former consists in the fact that cases which smell (and the odour is one of the most characteristic features of these cases) do well, while those which do not make no headway The bacteriological observation consists in the discovery that a certain bacillus is apparently constant in the wounds which emit the odour, while it is absent or cannot be recovered from those which do not smell

7 This bacillus is a spore bearing anaerobe of a saprophytic nature and belongs to the proteolytic group of organisms—the group which includes *B tetani* and *B œdematis maligni*

8 Unlike these latter, it appears to be non pathogenic to the animals experimented on, and what is of more importance, appears to be non pathogenic for man when introduced into wounds Further unlike the above-named pathogenic varieties, it does not appear to set free any toxins injurious to the patient in the course of its action on the dead tissues

9 A brief outline of the morphological and cultural characters of the organism is given its probable mode of action and the results of animal experiment

10 While it may be one that has been fully described before, we make no attempt in this paper to identify it with such in view of the somewhat chaotic state of our knowledge regarding anaerobes Hence for convenience sake, we call it the *Reading bacillus*

11 It acts, apparently in virtue of its proteolytic powers only on devitalised tissue and possibly on tox albumins and appears to possess no power of attacking healthy structures

12 Special stress is laid on the necessity of recognising the fact that one of the chief factors which keep a wound septic is the presence of devitalised tissue in that wound This acts as a base from which pathogenic organisms attack the body We would lay even greater stress on this than on the infecting organisms

13 The surgical or excision treatment of wounds apparently recognises this but only aims at removing macroscopically devitalised tissues, and in doing so inflicts a fresh trauma liable to reinfection

14 For this we propose to substitute the Reading bacillus in a living form, and it is probably present in most of the wounds if only given a chance to carry on its functions These are directed towards the removal not only of the grossly damaged tissue, but it succeeds also in attacking the microscopically damaged structures As a result the body forces are freed from the constant menace of septic poisoning thus allowing them to begin the work of repair

15 We give examples of gunshot wound cases which have been treated in various ways previously, including the salt-bag method, but without success These however, on being sown later with living cultures of the bacillus, have immediately started to do well and have ended in rapid recovery

16 The organism is probably present in the larger number of infected wounds but requires more or less anaerobic conditions before it can come into play

17 These are provided by the pack method of treatment, but we are inclined to think that salt is not a necessary adjuvant

and plays a very small role, if any This seems indicated by the fact that an inert substance like sphagnum moss for packing gives equally good results

18 It is essential however, that the wound be thoroughly well laid open in the first instance, exposing every pocket and sinus, so that the packing may completely fill the wound

19 We are conscious that many subsidiary points have still to be worked out, and even some of the above statements may have to be modified We feel, however, that the underlying principles are sound and offer a true explanation of the phenomena which have been described by those who have used salt bags It sounds heresy to advocate the introduction of living organisms to a wound, and, above all, anaerobic spore bearers, but it has been done with success by us In view, therefore, of the urgent needs of the moment, we offer these results of our investigations, carried out amidst much routine work, as we feel convinced that a knowledge of them will lead to further developments, and such knowledge ought to be shared *now* with others who may have opportunities for the investigation of a larger number of wounds than we have

20 Further investigation is proceeding, and it is hoped that we shall be able to make a communication later

LIQUID-TIGHT CLOSURE AND THE TREATMENT OF WOUNDS

BY WALTER H TAYLOR, M D, C M TORONTO,
AND
NORMAN B TAYLOR, F R C S EDIN,
CAPTAINS C.A.M C

IN the summer of 1916 convoys arrived at base hospitals in France with many bad-looking wounds, their dressings dried and caked owing to suspension of treatment during transit With free incision, the employment of drainage tubes, and a solution of eusol, the majority of these wounds did well Too often, however, they failed to respond, and in these cases post-amputation dissection indicated that crevices of the wound had not been reached by the solution

At that time we had not heard of Carrel's method, but the importance of bringing fresh solution in contact with as large an extent of the wound cavity as possible seemed obvious To this end we thought of creating an ebb and flow in the wound by repeatedly filling it under pressure and allowing the fluid to escape A catheter was inserted having a hole about its middle discharging in the centre of the wound and its lower end tied off The escape of fluid was obstructed by plugging the wound openings with gauze Irrigation was regulated by a clip on the tube connecting the catheter with a reservoir

Distension of the wound occurred during flow, followed by leakage and collapse of its walls when the flow was stopped, thus furthering the mixing of fluids in the wound much as the interchange of gases is promoted in the lungs by the act of breathing In a sense the wound was made to breathe

This "tidal movement" in the wound we regard as important It is essentially a cleansing action A nurse employs it in rinsing a sponge by squeezing it in a basin of water In wounds whose ramifications are many and tortuous this plan is particularly efficacious and, in our hands, has given excellent results

Closely associated with this washing of the wound is its ventilation Many surgeons leave wounds open to the air for this purpose It is to be remembered, however, that air or oxygen makes contact with the tissues only through the medium of fluids Exposing a deep wound to the air is of little avail unless air containing fluids are made to penetrate its depths This precisely is what tidal flushing does

These first cases in which we plugged the wound openings with gauze made notable recoveries But the expenditure of fluid was excessive, resulting in troublesome leakage into the dressings and thence into the bed The value of the procedure was appraised correctly by a nursing sister who remarked that the cases did well enough, but that the mattresses were ruined

Carrel obviates much of this by using small calibred tubes and by apportioning the amount of fluid injected to the size of the wound But the user of this method is on the horns of a dilemma—if too much fluid is injected he will have leakage and wet beds to contend with, yet if he does not use "too much" he cannot be certain that the fluid is coming in contact with the whole interior of the wound It requires tension in the wound for this, and tension spells overflow Moreover, such careful regulation of the fluid in the absence of any convenient means of flushing the wound encourages the accumulation of pus and débris which blocks the tubes, necessitating frequent dressings On ambulance trains the multiple tube method of irrigation is at a greater disadvantage

From these considerations, then, tension in the wound being necessary if tidal movements are to be had, and tension being impossible without closure it appeared to us that some trustworthy system of watertight closure was needed in the treatment of wounds

The First Device its Mode of Use

This object was first attained by means of a rubber bag after the pattern of an ice-bag, shown in cross section (Fig 1) A soft rubber collar is formed in the centre of the "top sheet" T This collar is closed by the clamp M Fitted in the wall of the collar is a glass cannula whose end outside the collar is connected with the inflow tube, and its end within the collar, with a tube leading to the bottom of the wound Another cannula, similarly fitted in the wall of the collar, has the outflow attached to it The under side B, the skin sheet, is of very thin rubber It adheres to the skin around the wound, a hole having been cut in this sheet a little larger than the wound opening, through which the wound cavity communicates with the interior of the bag

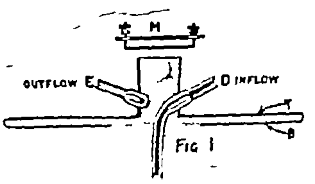

FIG 1

The wound is prepared by passing strips of rubber into any pockets that exist Their outer ends are tied together and cut flush with the skin These act as props to keep passages open, so that a positive pressure in the main channel of the wound becomes transmitted easily to deeper parts The rubber tube which is to be connected later with the proximal end of the inflow cannula is now passed to the bottom of the wound The skin is dried and painted with a solution of Canada balsam and rubber The drainage bag is then applied, the surgeon being able to see through the open collar that the hole in the skin-sheet is registering round the wound The tube in the wound is connected with the inner end of the cannula whose outer end connects with the inflow tube The outflow tube is connected with the outer end of the other cannula Both sides of the bag are then bandaged together and to the limb, leaving the collar protruding During irrigation the fluid extravasates between these sheets, exerting pressure which holds the skin sheet down the bandages serving as a *point d'appui* The sheet of rubber cemented to the skin round the wound constitutes a stop-valve, preventing leakage, any attempt of the fluid to escape beneath it being countered by its own pressure upon it When the outflow is clipped tension occurs in the wound relative to the height of the reservoir When the inflow is clipped siphonage creates negative pressure which is relative to the column of fluid from the bed to the floor

Report of Cases

Over 20 cases have now been treated with one form or another of this device with gratifying results Many of the wounds treated were shallow and uncomplicated by crevices but we have selected the following six cases for the opposite reason —

CASE 1—Corporal L—— admitted to Granville Special Hospital Excision of the knee had been performed following septic infection of the joint. For 12 weeks the discharge was most profuse Latterly the condition was less acute, but the sinuses which communicated with one another one on the anterior aspect of the knee and one on each side of the tibial tuberosity were most intractable to treatment The tissues for the last six weeks had been tender indurated, and swollen. The temperature at this time was normal, except for an acute flare up" every few days accompanied by a sharp rise Ordinary irrigation and moist dressings had been used for weeks with scarcely any change The drainage-bag was applied and the patient shown how to control the flow himself Eusol solution was run in and out for a few seconds every half hour After 24 hours, on opening the collar of the apparatus to examine the wound it was found that no pus could be expressed from the opening of, or along the track of the sinus. The tissues were healthier-looking and less tender to the touch The patient, who had complained of a dull aching pain in the joint from the first now volunteered the information that this had entirely disappeared. The apparatus was removed on the fourth day when a few drops only of serous discharge could be expressed from the anterior sinus The two lateral openings which communicated with the anterior were healed a week after the bag was removed, the anterior sinus exuding serum only for a week or ten days longer No recurrence of the infection occurred and a month later he was able to bear weight on the limb.

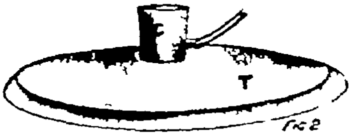

Fig 2

CASE 2.—Private J—— admitted to Ontario Military Hospital with a badly infected compound comminuted fracture of the left thigh and a tunnel wound through the upper end of the right tibia, also badly infected The patient was in a "typhoid state" with involuntary fæcal movements. The left thigh was amputated shortly after his arrival and at the same time the wound through the tibia was curetted and spoonfuls of black foul smelling cancellous tissue removed The end of the tibia appeared so friable that there was danger of breaking into the joint A split tube was passed through and through, a drainage-bag applied to each opening and irrigation instituted with pressure of a 3 foot column of fluid—Dakin's solution. The device remained effective for three days and was not reapplied Treatment was continued by merely flushing the solution through the wound It is difficult to draw deductions in this case on account of the accompanying condition but this ominous-looking wound took the right course instead of the wrong one the patient made a good recovery and he will have a good right leg as infection did not extend to the knee-joint

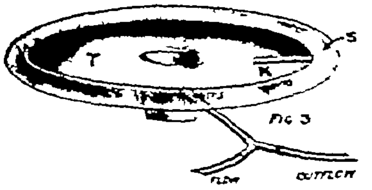

Fig 3

CASE 3.—Private S—— admitted to Granville Special Hospital with large discharging wound of thigh Very little improvement had been noticed in the past four weeks There was a deep sinus leading into soft tissues surrounded by an area covered with dirty greyish granulations discharging freely A drainage-bag was applied for seven days and eusol introduced under pressure every half hour during the day and every hour at night for the first 48 hours On removing the bag there was scarcely any discharge from the sinus, and the granulating surface was clean. Moist dressings were then applied daily In three days the sinus was closed and the surrounding area filling in rapidly with healthy granulations.

CASE 4.—Sergeant —— admitted to Granville Special Hospital with wound of upper arm, which had been discharging for the past six weeks with scarcely any change There was no sequestrum or foreign body Tortuous sinuses extending above and below the wound were indurated tender and of a purple colour The wound recently had become acutely inflamed the tissues around much swollen and discharging profusely the evening temperature was 102° Hot fomentations and ordinary irrigation produced little alleviation of these symptoms The drainage-bag was applied and hot hypertonic saline introduced every half hour under pressure the patient controlling the flow himself In 12 hours he was entirely free from pain, while tenderness and swelling were markedly reduced, the temperature was normal that same evening After two days the fluid came away clear though the intervals between irrigations had been increased The bag was removed on the fourth day all induration, redness, and tenderness having disappeared, the wound showing only a small amount of sero-purulent discharge A week later the sinuses were closing well they were perfectly pliable and free from oedema, a condition which had not obtained since his original infection.

CASE 5.—Private S—— admitted to Ontario Military Hospital with compound incomplete fracture of the femur There was a wound three inches in diameter on the anterior surface of the thigh leading to the medullary cavity through a hole in the bone. The thigh was tremendously swollen and very painful to the touch. There was profuse discharge, dirty brownish red in colour The patient's general condition was fair pulse quickened temperature 101° The surgeon in charge of the section thought possibly it was a form of gas infection and advocated multiple incisions of the limb but consented to give this scheme of drainage a short and summary trial. In two days the swelling had practically disappeared the discharge was lessened in amount and changed in character to a creamy-coloured pus Both temperature and pulse had improved, the case having lost the aspect of an acute condition

CASE 6.—Sergeant —— admitted to Granville Special Hospital with compound fracture of the femur and over riding of the fragments There was a sinus on the outer aspect leading inward between the fragments, also a wound below this leading into a large abscess cavity Both these wounds had been discharging profusely for six weeks or more The whole thigh from the lower third to the anterior superior spine was greatly swollen tender and oedematous. The temperature ranged between 99° in the morning to 101° at night, pulse 118 to 120 per minute The patient was despondent irritable and thoroughly miserable Latterly eusol had been injected into the sinuses but without pressure the fluid returning as easily as it went in. The temperature dropped to about 99° in the evening but did not fall below 99° in the morning and there was little if any change in his pulse-rate or in his general condition. The drainage-bag was then applied covering both wounds and the solution introduced, alternating positive with negative pressure Clipping off the waste-tube caused the collar of the bag to balloon up, while clipping the inflow caused its sides to suck vigorously together We inferred that to some extent the same thing was happening within the wound itself and to a lesser extent in the remotest reaches of the wound—i e tidal movements For the first 24 hours drainage was free, the fluid coming away loaded with pus At the end of 24 hours the evening temperature was normal for the first time for over six weeks The induration tenderness and swelling were reduced to a remarkable extent at this time At the end of 48 hours the fluid came away comparatively clear after each half hourly renewal of the solution On the third day owing to blockage of the sinus, there was a sharp rise of temperature and pulse-rate which as rapidly subsided when the obstruction was removed Two days afterwards the bag was taken off the temperature was below normal pulse 80 per minute and only a small amount of serous discharge exuded from the wound. The swelling pain and tenderness of the thigh had entirely disappeared the tissues were perfectly pliable and could be pinched up anywhere with the fingers Four days after the removal of the bag the lower wound was quite closed the upper wound closed a week later The immediate improvement in the general condition mental outlook appetite and well being of this patient was little short of astounding His pulse-rate which had been running from 116 to 120 per minute for over six weeks, dropped to 72 in a week from the commencement of the treatment There has been no recurrence of the infection

These cases at least are suggestive in view of the reasons propounded why 'active' irrigation should be more effective than "passive" Theoretically, the more inacessible the infection the more definitely should this plan disclose its relative worth And the theory appears to have been vindicated by the clinical course of cases with tortuous sinuses leading down to fractured bone The success of Carrel's method is due to the better distribution of the solution Liquid tight closure enables us to bring the fluid even more completely still in contact with the tissues

Improved Form of the Device

The device (Fig 1) that we have used in these cases stays watertight from three to five days at a time, after which its removal and its reapplication if the wound is not sufficiently sterile, is necessitated by leakage This is inconvenient, since the rubber is still quite adherent to the skin except along the track of a radiate wrinkle which has formed very gradually and through which the fluid escapes

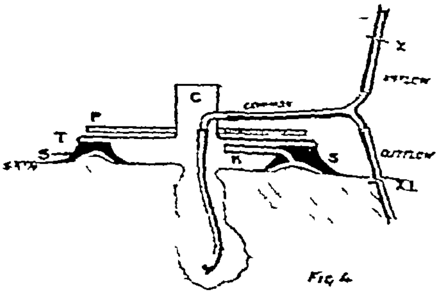

Fig 4

But the apparatus as we have it reconstructed now is much more dependable easier to apply, and the period of its effective use has been extended indefinitely

Fig 2 is a perspective view of the top side of the device Fig 3 shows the under side Fig 4 is a sectional view, and Fig 5 shows the device as it appears when bandaged to a wounded thigh

The same letters refer to the same parts The collar C and the top-sheet T are practically the same as before Instead of the skin sheet we have the "suction ring" S attached to the circumference of the top-sheet Round the under surface of S a gutter is formed, the sharp rubber lips on either side of which are designed to grip the skin A small tube, K, leads from the gutter to the space beneath the collar A valve on this tube lets air pass from the gutter and holds the suction by blocking its return The drainage-tube from the wound connects with a cannula in the collar, whose outer end connects with a common tube This common tube divides into an inflow and outflow a few inches from the collar by means of a Y piece There is a clip, X, on the inflow, and another clip XI, on the outflow

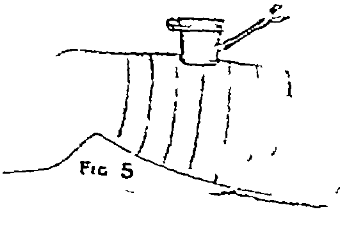

Fig 5

To apply, first paint the skin with a mixture of petrolatum, Canada balsam, and rubber dissolved in ether Petrolatum alone serves very well, but it attacks the rubber We do not want to cement the rubber to the skin as before, but merely to provide a "filling" to obviate the possibility of capillary leakage and to protect the skin These ingredients in equal parts make a soft elastic paste that is not too sticky The device is laid on so that the suction ring rests on sound skin with the wound more or less in the centre The washer P, of plastic felt, is now moulded to the suction ring and pressed down all round until the rubber lips make contact everywhere with the skin When the felt has hardened a little cotton may be tucked between it and the ring wherever contact of the lips is not perfect The ring is very flexible, and its attenuated lips can easily be made to conform to an irregular surface When the bandage is applied over all the air which is thereby expressed from the gutter through the small tube K cannot return on account of the valve Thus we have suction operative in addition to the pressure of the bandages, even before the irrigation is started After connecting the drainage tube to the cannula the collar is closed

To flood the wound close the outflow, when the fluid overflows and extravasates into the space between the top sheet and the top of the suction ring Here the pressure operates to force the suction ring against the skin, using the bandaging as a *point d'appui* as before This is additional to suction beneath the ring, which is still maintained by the valve

To suck the wound out, close the inflow tube and open the outflow, when siphonage aspirates the wound, collapses the collar, and renews the negative pressure beneath the suction ring through the tube K

When flooding a wound under pressure leakage is blocked by the same forces which, when a bath is filled, operate to draw the plug to the mouth of the waste pipe and hold it there—the weight of water above the plug and the column below it acting simultaneously

Several alternative procedures may be adopted in the intervals between the irrigations On the one hand the wound may be left distended, either with the outflow closed and the inflow open or the outflow almost closed and the inflow open, in which case the fluid dribbles slowly through the wound while positive pressure is maintained (If it is desired to have the flow thus continuous the connexion of the in and out-flow tubes with the collar will need to be as shown in Fig 1, which is perhaps the best arrangement in any case) On the other hand, the wound may be left collapsed, and either with the inflow closed and the outflow open or the inflow almost closed and the outflow open, in which case the fluid dribbles through whilst negative pressure is maintained A negative pressure persisting should encourage an outward flow of lymph

Or a dry wound may be had in the interval After siphonage the collar may be opened, when air replaces fluid as it gravitates toward the end of the drainage tube which is at the bottom of the wound The grip of the suction ring on the skin may be released by lifting the outer lip to permit the entrance of air

If the wound is a through and through one a similar device with its tube K, but unprovided with a collar, is applied to the lower opening Its suction ring is influenced, too, by negative pressure in the wound

Criticisms Answered

An objection that is often raised is that the wound is sealed -In the intervals between the irrigations, it is true, fresh fluid with its quota of oxygen is locked within the wound But the tissues can suffer no ill effects from this before the contained fluid becomes appreciably vitiated, which takes time And since bed flooding places no limit to the frequency of the irrigation, and the manipulation of a clip is all that it entails, it might at least be given often enough to obviate this objection Besides as just explained, the fluid may be allowed to dribble through the wound during the intervals between the flushings

Another contingency suggested is that separation of muscular planes, injury to the tissues pain, &c, might result from pressure of fluid in the wound Of course, pressure may be reduced to the vanishing point if desired, by lowering the reservoir But we are inclined to lay stress on the value of pressure

Taking pain as the criterion of the injury that pressure is inflicting, our experience has been that when the limb is snugly supported by bandages a four foot column of fluid may be borne without discomfort Nor have we found that any ordinary pressure is competent to separate muscular planes, and certainly not without pain as a warning symptom It goes without saying that pain is not allowable in any case

If pressure in a wound causes injury it must do so not by direct compression of the tissues but by distension—actual stretching of the walls of the wound It is distension certainly that causes pain, for it is not found that submersion of an inflamed member to a depth of two or three feet produces pain The larger the wound cavity the greater the area exposed to a given head of pressure, and the more forcibly the tissues are stretched by it Bandaging checks undue distension of the larger spaces of a wound, yet allows the fluid to enter subsidiary crevices in which infection is prone to lurk, yet which on account of their diminutive size are less sensitive to distension

Mouths of pockets may have become agglutinated, and it is, we think, the disintegrating action of pressure and suction that carries the wall and allows the solution to penetrate, rather than the action of pressure alone This "activity" of the irrigation promotes the mechanical washing of bacteria from the wound, and may explain the rapid clearing up of certain wounds which we have observed from the employment of solutions whose antiseptic value is negligible.

Another theoretical fear is that protective barriers might be broken down, causing the infection to spread The answer to this is that it has not done so, that, on the contrary, infections have been rapidly controlled The positive pressure in the wound is momentary In the intervals between the irrigations negative pressure should facilitate an outward flow of lymph Yet the volume of fluid used and the frequency of the irrigations should maintain the concentration of the antiseptic unimpaired

We hesitate to call this a modification of Carrel s method, of which already there have been too many It is true nevertheless that the use of our device implies no departure from his teachings On the contrary, it allows the doctrine of prolonged and intimate contact with every portion of a wound, by a solution whose concentration remains constant, to be more consistently applied

Summary

This whole question seems full of interest, and of promise for the treatment of wounds Tentatively, at least, we may summarise its advantages as follows —

1 Alternate tension and collapse in a wound providing deeper penetration of the solution employed and more perfect oxygenation of the tissues

2 A constant degree of concentration of the solution in the wound

3 More thorough mechanical removal of pus cells and bacteria from the wound

4 An outward flow of lymph

5 Economy of time and effort with ability to irrigate wounds more frequently

6 Elimination of the personal equation, the height of the reservoir and the opening and closing of a clip comprising practically all the instruction to be given or remembered

7 Inspection of the wound without undoing the bandages, by simply removing a clamp from the collar

8 The possibility of keeping an absolute record of the progress of an infection The washings of the wound for any given period containing all the pus cells and bacteria collected by the wound during that period, which could be counted and compared with any subsequent period

9 Saving of material—gauze and cotton—should more than counterbalance the cost of the device, which could be used over and over again

10 Comfort and sense of dryness enjoyed by the patient

11 For obvious reasons it would appear to offer an ideal method of treatment for use on ambulance trains

12 It is not suggested that this device should be employed in the shallow type of wound, where the ordinary methods suffice, but in wounds that are deep and inaccessible It would seem to promise most in compound fractures of the femur

We wish to express our gratitude to Surgeon General Foster C B, Director of Medical Services, Canadians for the facilities accorded us to carry out this work, and to Lieutenant-Colonel G E Armstrong, consultant to the D M S, whose interest in our scheme has been most helpful We are indebted likewise to Colonel D W McPherson and to Lieutenant-Colonel J T Clark, the officers commanding respectively the Ontario Military Hospital and Granville Special Hospital, for permission to report these cases

AN OPERATION FOR THE RADICAL CURE OF INGUINAL HERNIA

BY R V SLATTERY F.R.C.S IREL.

CAPTAIN ROYAL ARMY MEDICAL CORPS (T F) ASSISTANT [illegible]
RICHMOND HOSPITAL, DUBLIN AND SURGICAL SPECIALIST
NO — GENERAL HOSPITAL.

ANY successful operation for the radical cure of inguinal hernia must aim at re forming the damaged inguinal canal, making it "narrower and more resistant to abdominal pressure than the original canal had been"[1] The operation I am about to describe has the additional aim of re-forming the stretched internal abdominal ring

I should like, first of all, to refer to a few important points in the normal and pathological anatomy of the inguinal region

In the inguinal region the fascia transversalis stretches from the lower border of the transversalis muscle to Poupart's ligament to form the fascial floor of the inguinal canal. Half an inch above the mid point of Poupart's ligament the spermatic cord leaves the abdomen surrounded by the infundibuliform fascia. Normally a small well-defined ring can be demonstrated where the infundibuliform fascia leaves the fascia transversalis This constitutes the internal abdominal ring During abdominal strain the strong internal oblique muscle supports this fascial ring and reinforces the fascial floor of the inguinal canal

The pathological conditions accompanying a hernial protrusion are 1 A stretching of the fascial internal abdominal ring and fascial floor of the inguinal canal The ring enlarges in an inward and upward direction until it eventually overlaps the external abdominal ring 2 A resulting upward displacement of the muscles which are inserted into the conjoined tendon. 3 A stretching of the aponeurosis of the external oblique

In the present writer's opinion the importance of repairing the defect in the fascia transversalis in an operation for the radical cure of an oblique inguinal hernia has never been fully appreciated In this region, as elsewhere, the fascia transversalis must be looked upon as part of the extra peritoneal fascial envelope of the abdominal cavity A post-operative defect in this fascia, especially if it be left unsupported by strong muscles, invites a hernial protrusion. Therefore any operation which leaves a large or unsupported defect in the fascia transversalis or interferes with the support which the internal oblique muscle normally affords in the inguinal region must fail

BLOOD PRESSURE AND SURFACE TEMPERATURE IN 110 CASES OF SHELL SHOCK

BY EDITH M N GREEN, M B LOND ,

RESEARCH SCHOLAR UNDER THE MEDICAL RESEARCH COMMITTEE, WORKING AS ASSISTANT TO MAJOR F W MOTT F R S , AT MAUDSLEY HOSPITAL.

THE cases were Expeditionary Force men, and the examination was made on admission and at regular intervals through the man's stay in hospital

Observations on Blood Pressure and Condition of Patients

It was found that 55 men showed on admission a pressure below 120 mm Hg, and of these 25 were between 88 and 110 These were the severe cases of shell shock. Of the other 55, 28 were between 130 and 150 mm Hg, and 27 between 120 and 130 Of those above 130 only 4 were severe cases With the exception of 8 men, all showed subnormal surface temperature, varying from 18° to 31 5° C The temperature was taken in the hand with a surface temperature thermometer, the temperature of the air and a healthy control being noted at the same time

All of the cases with a very low blood pressure were suffering from dreams which woke them in a state of terror, sweating, and trembling Their hands were dusky and clammy, and most of them had a tremor They showed a marked fatiguability and irritability, most of them were depressed and showed a great lack of self confidence and initiative , all suffered from headache On admission nearly all had dilated pupils

Of the men with a blood pressure above 120 only 10 complained of nightmares, and in these the signs of fear were not so well marked as in the cases with a low pressure. In all cases, whatever the blood pressure, headache was a common symptom

An improvement in the general condition was coupled with a gradual rise of pressure This is shown in Chart 2, which is a typical example At the same time the dreams became less terrifying and there were fewer signs of fear In some cases which had shown a return of symptoms—such as nightmares, tremors, headaches, or had some cause for considerable worry—it was found that there was a drop in blood pressure at the same time This is also shown in Chart 2 In most cases there was a rise of surface temperature as the general condition improved, though any subsequent fall in surface temperature or blood pressure did not always coincide

No case showed any organic lesion, and the urine was normal

As a gradual rise in blood pressure was found to coincide with general improvement in condition, pituitary and thyroid extract were given in order to see whether a general improvement could be obtained more quickly

An interesting point was the almost constant relationship between the low blood pressure and terrifying dreams It seems as though the vaso-motor disturbance which was produced at the time of the shock was rendered more or less permanent by the constant repetition in dreams of his former terrifying experiences At the same time the low blood pressure caused a cerebral anæmia and lessened mental and physical activity, which prevented the man from throwing off the effects of his imagination—thus a vicious circle being produced A gradual or rapid rise of blood pressure in nearly every case was accompanied by a change in the character of the dreams, the terror element being less marked

Results of Treatment

Treatment with pituitrin —This was tried after general treatment and other drugs had failed Twenty cases were treated with pituitary extract 15 were watched for some weeks, 5 improved very rapidly and were sent to convalescent homes before full notes could be taken Chart 1 shows progress in 10 cases

It was given (1) as pituitary fluid 0 5 c c b d as an injection , (2) as ext pituitrin gr ii t d s Better results were obtained from extract Five patients who were given injections complained of dizziness afterwards, no case treated with extract complained Administration was followed by an immediate rise in blood pressure—in one case from 100 to 122 There was a marked improvement in appearance, less depression, less headache, greater feeling of well being less fatiguability Eight cases complained of polyuria (5-6 pints of urine a day) The pituitrin was discontinued until the amount of urine became normal and then was given once a day

A slight drop in blood pressure was noticed in 6 cases when pituitrin was discontinued but not to the original level

Three of the most marked cases were given other pills instead of pituitrin for 2-3 days to eliminate suggestion as a cause or factor in the improvement In 2 cases there was a slight return of headache and the men did not feel so well

The pituitrin was given to one man with a blood pressure of 150 who was suffering from marked depression headache insomnia, stammer, and nervousness After three doses the headache and depression were markedly improved , he showed more self confidence , his blood pressure dropped to 130 He attributed the improvement to the new treatment, and when the supply of pituitrin gave out it was noticed that he relapsed The drop in blood pressure was not noticed in any other case, and this case is merely quoted because it was unique

Treatment with Thyroid Extract —This was given in doses measuring from gr ¼ to gr i t d s to 20 cases In 13 cases improvement was noticed, a gradual rise in blood pressure and lessening of headache being produced Coupled with pituitrin the effect was more rapid

No other gland extracts have been used

Histories of Cases A to K (explaining Chart 1)

A.—Lance-Corporal R H aged 26 (also Chart 2) Out to France February 1916 feeling very fit On July 1st he was blown up by a shell He has a faint recollection of crawling out of some water but remembers no more until he found himself in a dug-out, dumb, partially deaf and blind for a few minutes.

When admitted to Maudsley Hospital on August 17th he was mute his hearing was normal there was slight left facial paralysis. His hands were very dusky sweating cold and slightly tremulous His dreams were very marked he used to wake sweating and terrified after going through a pantomime of bomb-throwing He had headache and was depressed Blood pressure and surface temperature were subnormal he was always complaining of feeling cold.

Sept. 25th He was able to speak in a whisper His other symptoms were improving slowly His dreams were still frequent but less terrifying

Nov 25th-28th All his symptoms returned after hearing of the death of his brother in action Put on ext. pituitrin gr ii t.d.s This was followed by an immediate rise in blood pressure, together with marked general improvement less headache and depression His bomb-throwing still persisted but he was much less exhausted on waking After seven days treatment his surface temperature began to rise and he himself noticed that he was much warmer

Pituitrin was discontinued after one month s treatment but the improvement persisted

He was boarded out of the Army in February and wrote in March saying that he was still feeling better

B —Sergeant J K aged 34. Blown up by a shell in November 1916 (Had been in India in 1908 and suffered from malaria) On admission he complained chiefly of suprаorbital and vertical headache, together with dizziness His blood pressure was 104 and dropped to 92 when he was put on pituitrin There was an immediate improvement in headache blood pressure rose to 98. There was polyuria (6 pints) and the dose was given once a day only The headache continued to improve and he was sent to convalescent home and later to his depot

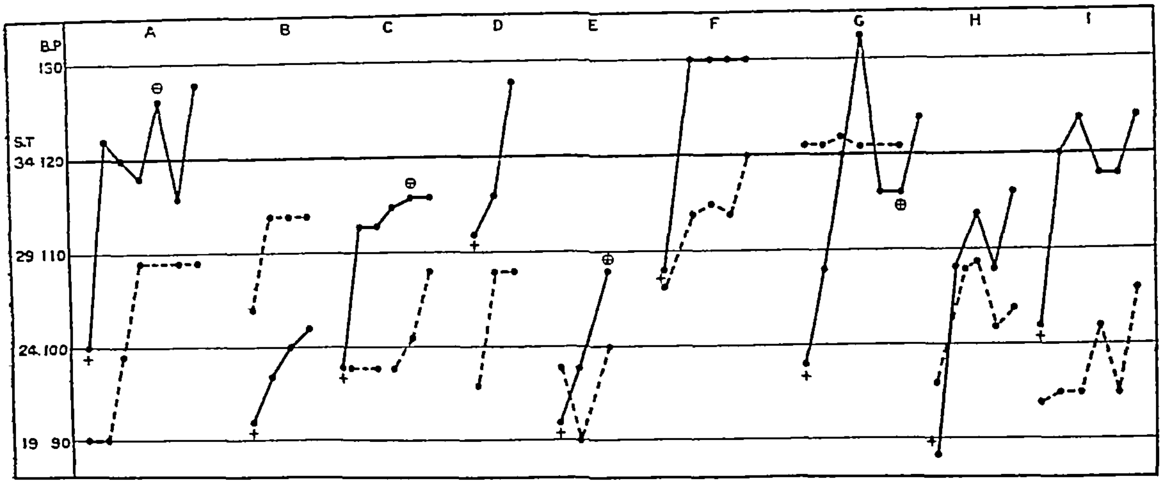
C —Gunner J W aged 25 In October 1916 while helping to lift ammunition fell down with severe pain in lower part of back On admission to Maudsley Hospital he complained of severe occipital and temporal headache He was troubled with nightmares and was very neurasthenic. While in hospital he became tremulous on excitement and his headache increased He was given pituitrin which raised his blood pressure from 98 to 114 and improved the headache. The blood pressure remained up when the pituitrin was discontinued but he remained neurasthenic Boarded out.

D —Gunner D aged 22. After 25 months service in France he was buried in a dug out, when his gun blew up in October 1916 On admission he had marked vertical headache his hands were dusky and tremulous and his pupils were widely dilated He had nightmares After one week s treatment with pituitrin his headache was much improved Sent back to depôt

E —Private D B aged 19 Patient had to go sick as result of barrage on Nov 18th 1916 On admission he had cold blue hands sweating body feeble pulse blood pressure of 92, terrifying dreams as soon as the light was put out at night. His general condition improved with pituitrin, but the supply gave out and he was sent to convalescent home

F —Private T aged 29 Admitted to Maudsley Hospital in July 1916, after being blown up on July 1st with marked tremor general exhaustion and signs of fear He had seen service in Gallipoli Egypt and France Patient improved up to the end of July and then he began to be troubled by nightmares, chiefly of aerial torpedoes. His state of fear was very marked and persisted until the end of September when he began to improve He was better up to November when he became much worse. He complained constantly of headache his sleep was disturbed by nightmares and he had loss of appetite His blood pressure was 98-103 After pituitrin there was immediate improvement. Sleep appetite and general condition all improved. Dreams persisted but were less worrying In this case the supply of tabloid form gave out, and he was given injections He complained of dizziness after these and it was noticed that he was much better after the solid form.

CHART 1



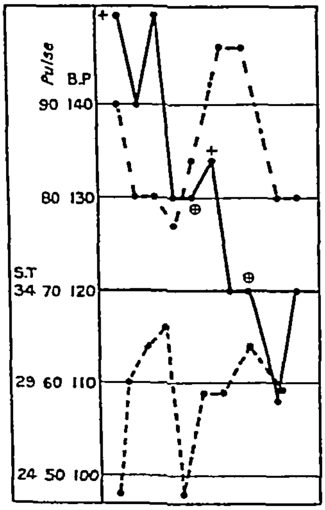
A—I Showing the effect of pituitrin on the blood pressure and surface temperature Each dot is one week s interval + is the pressure when the first dose was given ⊕ is the point at which the pituitrin was discontinued

G —Private N., aged 35 Admitted to Maudsley Hospital in April 1917 suffering from amnesia for whole of Army life, depression, marked occipital headache and slight confusion. He was put on pituitrin after general treatment had failed There was an immediate rise in blood pressure together with a marked lessening of his depression and general debility He complained a little of dizziness after injections and had polyuria (5 pints) and was given extract instead of injection. The amnesia persists but the general condition is still improving

H —Private D H aged 26 Suffering from acute confusional insanity following mumps and measles. Family history of insanity Blood pressure only 88 Hands nose ears and feet very blue and cold He was given pituitary fluid with an immediate rise in blood pressure and slight general improvement. Ten days later he was given pituitary and thyroid extract, but there seems to be no real improvement (There has not been sufficient time to watch for any further change)

J —Sergeant I L. aged 22. Sent back from Germany where he had been prisoner for 15 months as insane" He was in Giessen Asylum for 7 months. August 16th 1916 Admitted to Maudsley Hospital markedly depressed and lethargic. In October his general condition showed improvement but he still had periods of depression He was put on thyroid extract and in December he was given pituitrin. January 1917 No longer depressed or lethargic. (He complained of pain in his back, which was found to be due to a bullet this was removed)

CHART 1 K



Shows the effect of pituitrin in a case of high blood pressure

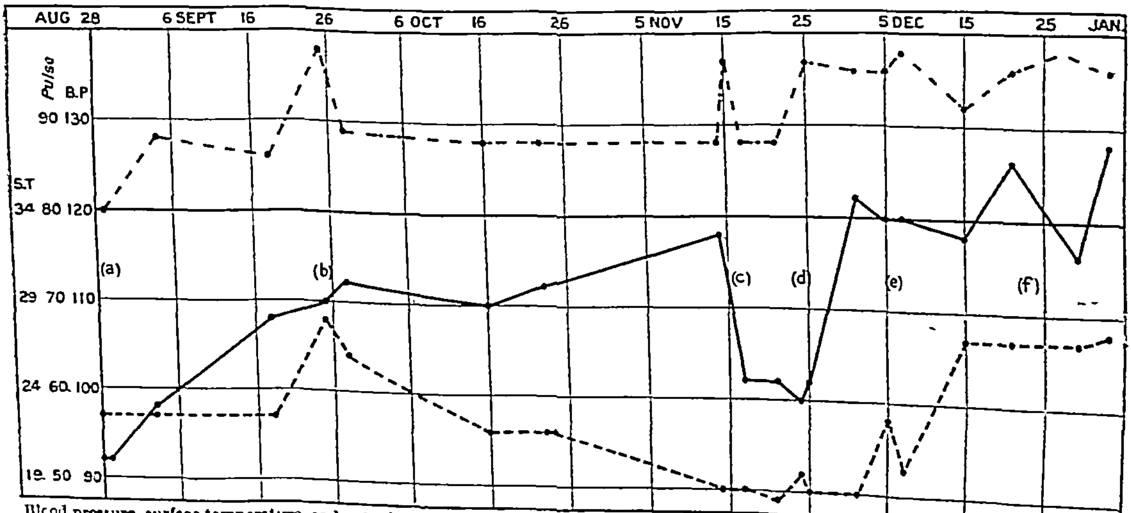
—— = Blood pressure
— — — = Surface temperature
- - = Pulse

K —Bombardier A aged 31 Admitted to Maudsley Hospital on Oct. 30th 1916 after 19 months active service suffering from headache and depression Blood pressure 150 He had similar attacks before joining Army Patient s headache did not improve under treatment, and on Dec 3rd he was given extract pituitrin, in spite of his blood pressure In two weeks the blood pressure dropped from 150 to 130 and there was less headache and depression and more self-confidence. Treatment was discontinued for one month and during this time patient again became depressed and tremulous Pituitrin was again given with improvement Blood pressure 120 Sent to convalescent home

In this case extract pituitrin improved the headache and was accompanied by a drop in blood pressure and polyuria.

The work was undertaken at the suggestion of Major F W Mott, R A.M C (T) who had already made some observations on the same subject, and who was in charge of the men, and to whom I am indebted for help and permission to publish the results The instrument used was Rogers's sphygmanometer, manufactured by Short and Mason Limited It was found that this could be manipulated more quickly than the Riva Rocci instrument, which was used for a time and from which the same results were obtained

CHART 2



Blood pressure surface temperature and pulse in a case of functional mutism (a) On admission troubled by nightmare (b) Able to speak in a whisper (c) Much depressed after bad news (d) Put on pituitrin (e) Marked general improvement (f) Taken off pituitrin

FRACTURED BASE OF THE SKULL

THE SUBSEQUENT HISTORY OF A CASE AND ITS TERMINATION 24 YEARS AFTER THE ACCIDENT

By J B CHRISTOPHERSON, M A, M D Camb, F R C P Lond, F R C S Eng,
DIRECTOR OF THE CIVIL HOSPITALS OF KHARTOUM AND OMDURMAN

With Bacteriological Note by Albert J Chalmers, M D Manch, F R C S Eng, D P H, *Director of Wellcome Tropical Research Laboratories, Khartoum*

It is not often that we can follow up a case of fractured base terminating 24 years after the original accident from the direct effects of the injury

One Sunday in March, 1917, I was asked to see an old gentleman of 65 at Khartoum, complaining simply of feeling a little giddy and of some discomfort below the occipital region of the head—nothing more He had a temperature of 104° F Next day (Monday) he appeared neither better nor worse He became unconscious and apoplectic on Tuesday, and did not recover consciousness before he died on Wednesday morning at 6 o clock

Account of the Case

The complete story was this Nearly 24 years ago (summer, 1893), whilst out riding he was thrown, and received a fractured skull He remained unconscious for two weeks, finally recovering, but with the loss of smell and taste He appeared to recover completely, excepting that any worry or extra exertion made his head ache at the back, this, however, was always put right by a day in bed and the administration of a little aspirin

He was a popular pleasant, cultured man, with a good memory, and a well known artist, who, during the war, had patriotically resumed his former business profession and was actively engaged in it at the time of his death He possessed all his faculties (excepting taste and smell) until 24 hours before his death In fact, four days before his death he was apparently in the best of health and spirits, as an active man of 65 should be, and he looked no older than 55, if as much

At the time of his death he was at Khartoum, a long way from England, the place of his accident of 24 years before The day on which he was first taken ill would be considered hot for any other place but Khartoum, but not unpleasantly hot for Khartoum at that time of year (the month of March) The maximum temperature on that day was 96 4° F , the minimum on the previous evening had been 64 8° He first noticed something amiss after he had walked along from his hotel to the club and back a distance of over a mile

At the club he had looked at the papers and had gone to sleep on the verandah He had walked back in the afternoon to his hotel, but was noticed on his return there to be unsteady in his gait Feeling unwell, he walked to see a doctor who lived a quarter of a mile away, not finding him in he returned to the hotel and went to bed He was seen in bed by the doctor at 9 o'clock on the same evening He had a temperature of 104°F , and the only thing he could definitely complain of was a feeling of discomfort which he located below the occipital region of his head It is necessary to remember this because subsequently it was found that he was suffering from a small abscess in his frontal lobe There were no other physical signs of illness, and he talked intelligently and with a good memory for events recent and remote and chatted of mutual friends of 20 years ago

When seen the next morning he appeared to be neither better nor worse, and it was supposed that whilst sleeping on the club verandah he had got "a touch of the sun" He really was suffering from a cerebral abscess in the frontal lobe and commencing convex meningitis, but this was not suspected at this time

He was seen at mid day and again at night The temperature being no lower (104 8°), it was resolved to take him into hospital in the morning, he had so far only been a little more than 24 hours ill The next morning at 6 o'clock he became comatose after getting out of bed, and passed into an apoplectic condition, struggling and breathing with considerable stertor and stridor Ice was applied to his head and he became quieter, he was removed to hospital but he never recovered consciousness

The only additional symptom noticed was inequality of the pupils, the right being fixed (The abscess was on the right side) He died 24 hours later, 84 hours after the commencement of his last illness

Necropsy

A post-mortem examination was made

The whole of the convex surface of the brain and the inner surface, that in relation to the falx cerebri, was invaded by a purulent meningitis which appeared to travel along the line of the big vessels The medulla oblongata and the spinal cord were quite free and there was no meningitis of the base at all, nor did it extend to the spinal cord, nor was the pus of the gelatinous greenish yellow appearance which one associates with the meningococcus of Weichselbaum It was not, in fact, a cerebro-spinal meningitis anatomically

On getting out the brain there was some difficulty in removing it from the right anterior fossa, and on examining the under aspect of the right frontal lobe there was a distinct thickening of the covering membranes which concealed the not very large abscess—a thumb nail would cover it—shown in the figure

I took out a wedge of skull to include the cribriform plates and neighbourhood of the anterior fossæ and found that the dura mater was thickened, and that this had been the seat of an old injury, and I thought that probably the abscess had originated through infection passing through a damaged cribriform plate of the ethmoid

The other organs were quite healthy

Causation

I wrote to his relatives and asked whether he had ever had an injury to his head and they replied that 24 years previously he had fallen from his horse whilst riding, injured his head, and remained unconscious for two weeks His recovery had been slow but apparently complete except for the loss of smell and periodical attacks of occipital headache when he over exerted himself These attacks were cured by a day in bed and a little aspirin There can be little doubt that an abscess had formed at the site of a fractured base and that it was the extension of infection from this along the lines of the great vessels that had caused the illness of the four days previous to his death

But when had the abscess formed? It was adjacent to the old seat of fracture, and it may be assumed that it was a consequence of the fractured base, whether it commenced immediately after the accident, or developed later, it is impossible to say Judging from the appearance and from the thickening of the dura mater about it, I should say that it was of long standing, and being in the "silent portion" of the brain it gave rise to no symptoms until it was accompanied by meningitis

The occasional slight attack of indisposition and pain in the head, cured by aspirin and a day in bed, were, may be small attacks of meningitis, the inflammatory process spreading beyond the confines of the abscess and becoming checked by suitable treatment

The micro-organism found not only in the pus but also in the abscess wall deserves mention, and I cannot do better than refer to the note which my friend Dr Chalmers most kindly made for me

Pathological report—"The sections of the frontal lobe of the brain contain Gram positive diplococci in chains, some of them having a Gram negative element"

For further details see Dr Chalmers's note at end of this paper

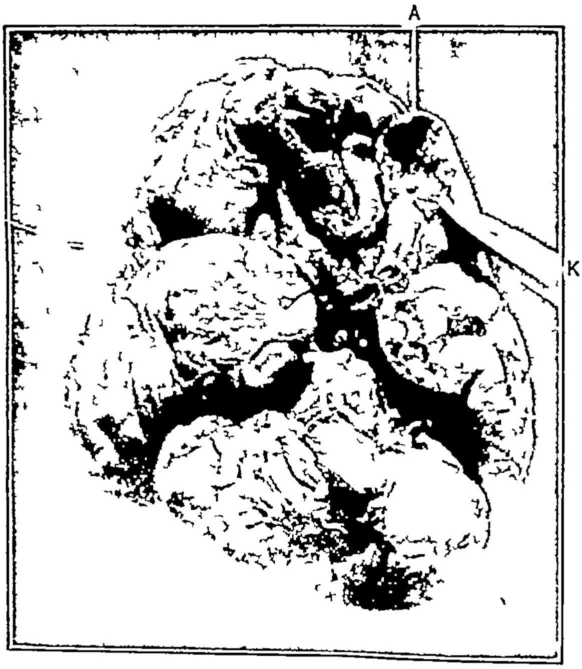
Remarks

In the "silent" regions of the brain, when dealing with the subject of cerebral abscess, the well known text-book of Osler says, "where the abscess becomes encapsulated there may be no symptoms" but it appears to me to be remarkable that this abscess had lain dormant, slowly forming, perhaps for years, had not even affected consciousness, or intelligence, or character, also that during the last four days of his life, when the local abscess became a general convex meningitis, there should have been only a high temperature and slight occipital headache, followed by apoplectic symptoms for the last 36 hours

The case deserves recording, I think, as a far reaching effect and far off termination of a fractured base I do not think that there can be the slightest doubt that the fracture through the right cribriform plate of the ethmoid gave entrance to the meningococcus which was neither Gram-staining nor non Gram staining That this meningococcus—not Weichselbaum's—produced an abscess in the under aspect of the right frontal lobe which was chronic and of long standing, that owing to the climatic conditions of the Sudan the meningococcus suddenly and rapidly spread all over the convex portion of the brain and involved the meninges of the vertex in a purulent meningitis which probably commenced four days before death

These are the facts Now for the reflections

1 It is unwise to prognosticate in cases of fractured base of skull. A fractured base of skull though apparently recovered from, is still a very serious thing It would seem that a man may live for 24 years and be none the worse to all appearances and may then die from the direct effects of his fractured base



From a photograph of the base (under aspect) of the brain showing the site of the abscess (A) and the knife-blade (K)

2 That the whole convex portion of the brain, including inner surfaces and the upper surface of the cerebellum, may be in a condition of progressive purulent meningitis and give rise to no definite signs except a temperature of 104° F and a little occipital discomfort and later a fixed right pupil and 24 hours before death unconsciousness and an apoplectic condition terminating in death without meningitis being so much as thought of

There is found out here in the Sudan and elsewhere a meningococcus both positive and negative in its Gram staining properties and which is not the meningococcus of Weichselbaum, and which is named by Dr Chalmers *Streptococcus janus crassus*

Could anything have been done for such a patient to relieve the abscess? I think not Its presence was not suspected, there were no localising symptoms, and it was not very accessible to operation if it had been diagnosed Whatever pain he had was in the occipital region, the abscess was in the inferior frontal portion of the brain He probably had it for a considerable time previous to his death perhaps for years and yet although situated in the frontal lobe on the inferior surface he had 'pain at the back of the head when he had worry or extra exertion

And finally a micro-organism such as this meningococcus when limited to its native habitat—in this case a smallish localised abscess—may remain harmless for years, but passing beyond these limits it may assume an acute and dangerous pathogenic state In this case passing from the abscess to the meninges it assumed a rapidly spreading and fatal character One may compare it to pathogenic organisms found constantly on the mouth tonsils or nasal mucous membranes quite harmless whilst they remain localised but by chance becoming transferred to more favourable media—meninges, lungs, other organs—they become virulently pathogenic

Bacteriological Note by DR ALBERT J CHALMERS

With reference to the Gram negative, Gram positive diplococci found separate and in chains in this case, organisms of a similar nature have now been met with several times in the Anglo-Egyptian Sudan They were first found by me in two cerebro-spinal contacts in Omdurman in 1913 later in a case of tonsillitis, then in a case of cerebro-spinal meningitis, then in a case of severe tonsillitis which was followed, after an interval of several days, by a scarlet-fever like eruption associated with desquamation and in a contact of that case, then in several other more or less severe cases of tonsillitis, of which the worst was followed by a scarlet-fever like eruption associated with desquamation Finally I have obtained an organism of this group from the blood of a case of septicæmia

I am inclined to the belief that the first time any of the organisms were recognised was by Jaeger in 11 cases of cerebro-spinal meningitis in Stuttgart in 1895, and I am also of the opinion that Jaeger's organism is the same as that named *Diplococcus crassus* by von Lingelsheim in 1906, and if so then it is the same organism as that found by myself and Captain O Farrell, R A.M C, in 1916[1] in a case of fulminating cerebro spinal meningitis in Omdurman because the two agree in cultural characters and in sugar reactions

According to the way I look upon the genera of the family *Coccaceæ* subfamily *Streptococceæ*, these organisms belong neither to the genus *Diplococcus* nor to the genus *Streptococcus* but to an intermediate genus, for which I suggest the name '*Janus*,' owing to the organism being both Gram-negative and Gram positive and differing in its cultural characters and chemical reactions from *Neisseria intracellularis* (Weichselbaum 1887), as set forth in the paper indicated above, and *Diplococcus crassus*, von Lingelsheim, 1906 would therefore become *Janus crassus* (von Lingelsheim 1906), and should be considered as identical with the organism which has been found in a case of cerebro-spinal meningitis and in contacts therewith and in carriers in the Anglo-Egyptian Sudan

The cultures kindly sent me from the above case were unfortunately contaminated, being obtained by post-mortem examination These contaminative organisms killed the other growths before I could separate them, but both they and the brain showed the presence of a Gram negative Gram positive diplococcus arranged in chains, and I am of the opinion that in all probability the organism in this case was *Janus crassus* (von Lingelsheim 1906) though of course definite proof is lacking

UNUSUAL RENAL CALCULI WITH SEVERE HÆMORRHAGE AS THE ONLY IMPORTANT SYMPTOM

BY JOHN D MALCOLM, M B, C M EDIN, F R C S EDIN,
SURGEON TO THE SAMARITAN FREE HOSPITAL.

THE very slight degree of pain and the close resemblance of the 18 small faceted stones to gall stones seem sufficiently unusual to make a note of this case interesting

A woman, aged 41 the mother of three children, the youngest born on April 7th, 1917, was healthy until her last confinement. Recovery from this was not good, but Dr G H Mitchell informs me that feebleness was the only symptom, and that nothing abnormal was observed in the urine at that time Six weeks after the child's birth it was noticed that the mother's urine was of a bright red colour, which continued with increasing weakness until, early in July, the patient fainted She had no pain and said she had not suffered in any way except from weakness, but later she allowed that for about seven years there had been an occasional stitch and dragging in her side on account of which she wore a very strong corset She insisted that the pain was nothing to complain of

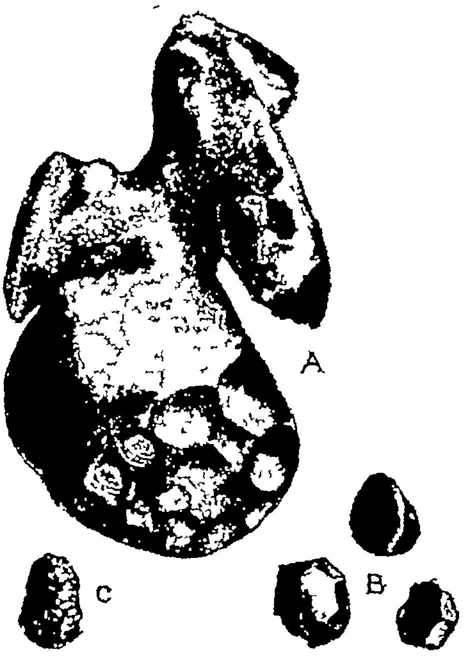
On admission to the Samaritan Free Hospital on July 11th her lips were almost as white as the rest of her face The urine contained much blood thoroughly mixed with it The inner side of the right kidney was easily felt and very hard, but it was not tender An X ray examination showed a large shadow in the *right kidney* region and a small one near the bladder in the line of the right ureter

---

[1] Vide Journal of Tropical Medicine and Hygiene May 1st and 15th

Calculi were diagnosed, but the combination of so much hæmorrhage with so little pain suggested that possibly there was some further disease I *therefore* opened the abdomen on July 20th to examine both kidneys, as removal of one might be thought advisable The left seemed a little firmer than usual, but was otherwise normal In the lower *end* of *the right* kidney many stones were felt moving on each other like gravel The ureteric calculus was also identified close to the broad ligament

The right kidney was brought out on the loin through a second incision with considerable difficulty on account of old adhesions to the peritoneum, and the latter was torn in the process of separation This kidney contained the large stone shown in the figure (A) Its various rough projections occupied different calyces The large smooth, rounded portion, part of which is faceted and 18 small faceted stones lay in a dilated calyx at the lower end of the kidney An average three of these small stones are shown (B) Many of them have one rounded surface which *evidently* was in *contact* with kidney substance *There* were few, if any, more than a single layer of these stones all, *or* nearly all, being in contact with the large one The renal calculi were removed through an incision into the lowest calyx slightly extended to release the branches *of* the big stone, one of which, not shown in the figure, was broken but came out entire The bulk of the renal tissue was healthy and no other disease was *found* A single suture closed the more fleshy divided part of the kidney, the thinned wall of the lower calyx being left unsecured The loin wound, except where an opening for drainage was left, and the tear in the peritoneum were carefully closed



A Large renal calculus B 3 of 18 small renal calculi C ureteric calculus (Natural size)

Through a third incision in the right groin the peritoneum was separated down to the ureter, a snick in which released the small rough stone shown in the figure (C) One catgut suture closed the opening The left hand in the peritoneal cavity was of the greatest assistance in locating and bringing into view the ureter and stone The groin wound was closed except for the presence of a drainage tube, which was removed on the third day The anterior incision was closed and union by first intention took place in all the wounds except at the points of drainage

There was very little discharge from the kidney, and no urine was detected in this discharge at any time by sight or smell The drain was gradually removed Hæmaturia ceased after four days but some albuminuria continued The patient was sent to the Samaritan Free Hospital Convalescent Home on August 11th, still very weak but making blood fast There was then only a small superficial wound unhealed in the loin

Wimpole-street, W

Reviews and Notices of Books.

Tumours, Innocent and Malignant, their Clinical Characters and Appropriate Treatment By Sir JOHN BLAND-SUTTON, LL D, F R C S Eng, Surgeon to, and Chairman of the Cancer Investigation Committee of the Middlesex Hospital, &c Sixth edition With 383 illustrations London Cassell and Co, *Limited* 1917 *Pp* 790 Price 21*s* net

ON its first appearance in 1893 Sir John *Bland* Sutton's book on tumours at once established its reputation as an authoritative and suggestive work on a subject of widespread interest and it has long achieved the position of an English *medical classic* From the preface to this the sixth, edition we learn that so long ago as 1885 Sir John Bland-Sutton began to collect material for his study of tumours and it is well known that he has retained his interest in the subject The successive editions of his book show how much enthusiasm and original thought he has devoted to it One of the features which have rendered this book *so interesting is* the manner in which it is illustrated by references to tumour growth in animals Sir John Bland Sutton points out the value of comparative pathology in elucidating some of the obscure problems in connexion with tumours, and his own profound knowledge of this subject has been in many instances applied suggestively with good results He admits at the outset that no one has succeeded in framing a satisfactory classification of tumours, and he adopts a histological classification as most convenient for purposes of description—viz, tumour diseases of the connective tissues, tumour diseases of teeth, epithelial tumours, endotheliomas, tumours arising from the fœtal membranes, teratomas, and cysts This classification at least has the merits *of simplicity* and convenience and involves no theoretical assumptions. Each group is then considered separately, and one or more chapters is devoted to a consideration of each variety in the group Among the connective-tissue group we need only mention the description of uterine fibroids, which, as might be expected, is a most interesting and instructive one, profusely illustrated by woodcuts of important specimens almost entirely from the author's own experience. Referring to the difficulties of accurate diagnosis in these cases Sir John Bland Sutton has framed some aphorisms on pp 228–229, in the mánner of Agur the Sceptic, which embody in convenient form some useful cautions.

To appraise a work on tumours one would naturally turn to the description of cancer and judged by this criterion Sir John Bland Sutton does not fall short His chapter on the cause of cancer gives within short compass a summary of the two chief theories the embryonic and the parasitic points out the great difficulties of the whole problem, and counsels patience and persistence in dealing with it The epithelial tumours are then dealt with according to their regional incidence the clinical characters and treatment of each form being succinctly and critically presented Among the other sections which are worthy of special mention we may refer to those on teratomas and dermoids which are both dealt with in an instructive and clear manner Sir John Bland Sutton writes well and is always happy in his allusions and illustrative similes We have read this new edition of his book with great interest, and can commend it to our readers

JOURNALS

The Journal of Physiology Edited by J N LANGLEY, Sc D, F R S Vol LI, No 3 Cambridge University Press. 1917 Pp 111–210 *Price* 6*s* 6*d* —The Metabolism of Arginine, by W H Thompson This is the third communication by the author on this subject and deals with arginine and creatine formation *Dogs* birds and rabbits were used Arginine carbonate given with food to dogs and ducks increased the output of total creatine in the urine. On the excretion of preformed creatinine the addition of arginine to the food in dogs and birds produced no effect Intravenous injection of arginine increased the creatine of rabbit's muscle which corresponded on the average to a storage of 14 5 per cent of the guanidine. From the experiments on rabbits it would seem that after arginine is injected into the circulation a portion of its guanidine nucleus is converted into creatine, some of which is stored, for a time a least, in the muscles, and part excreted in the urine —The Action of Guanidine on the Neuro-myal System of Decapod Crustacea, by J Smith Sharpe Guanidine in the vertebrate acts first as a stimulant and then as a depressant upon the motor cells of the spinal cord, and it also acts upon the neuro-myal junction in the skeletal muscles in the frog and mammal. Although crustacean and vertebrate muscles are structurally very similar, creatine is absent from crustacean muscle It would seem that in degenerate muscle after nerve section there is a marked fall in the creatine present. Another difference in the neuro-myon is that curare does not act on the neuro-myon in crustacea. The author finds that in crustacea guanidine salts produced jerkings and tremors of the muscles similar to those produced in vertebrates *This is due to* an action on the central nervous system as in mammals and not to an action on the peripheral neuro-myon as in the frog On these peripheral structures guanidine appears to be without action —On the Capacity of Blood and Hæmoglobin to Unite with Carbon Dioxide, by George A Buckmaster Blood as is well known, can absorb quantities of carbon dioxide Within limits the amount of gas absorbed would appear to rise and fall with the quantities of hæmoglobin present and therefore the quantity of the pigment is a determining factor in this matter Salt-free blood can absorb quantities of CO and within limits the capacity to do this augments with the percentage of hæmoglobin The author has not found much evidence to indicate that proteins free from salts can absorb this gas to any marked extent. Experiments showed that hæmoglobin is capable of taking up considerable amounts of CO_2 at pressures between 760 mm and 70 mm, pressures which do not normally occur in the human body So far the author has found that none of the proteins of the blood possess the property of absorbing carbon dioxide to the degree possessed by hæmoglobin. This pigment may behave generally like other proteins, but in addition possess a specific capacity for the absorption of carbon dioxide —A Comparison between Voluntary and Electrically Induced Muscular Work in Man by A. Krogh and J Lindhard. In 1911 Professor J Bergonié, of Bordeaux, constructed an instrument by which powerful rhythmic contractions of human muscles can be induced electrically with a minimum of unpleasant sensations The authors used a modification of this apparatus, combining it with the recording respiration apparatus of Krogh. Only the muscles of the legs were stimulated to avoid direct stimulation of the respiratory muscles The arm was used for pulse-rate The authors formulate the following conclusions —

1 The Bergonié treatment consists in rhythmic tetanisation of human muscles When applied to all the muscles of the legs it can without causing painful sensations raise the gas exchange to 1600 c c O_2 absorbed per minute 2 The effects on circulation and respiration of work induced by the Bergonié process have been studied and compared with those of voluntary work on the ergometer (*a*) The mechanism of the initial increase in pulse and ventilation rate is different in the two kinds of work. The increase originates, as a rule from cerebral impulses in voluntary work but is produced reflexly in induced A chemical regulation sets in later in both cases (*b*) During work—induced and voluntary alike—the pulse rate and circulation rate are linear functions of the metabolism but different in different subjects and dependent upon the state of training (*c*) The rate of ventilation is usually greater in induced work than in voluntary, corresponding to the same oxygen absorption This is probably due to afferent impulses from the stimulating currents 3 The direct effects of the Bergonié treatment as a cure for obesity are insignificant but the indirect effects produced by training of the muscles acted upon are probably considerable though we have not succeeded in demonstrating them in our experiments

The Oxygen Use of Denervated Muscle by J N Langley and M Itagaki. Denervated muscle rapidly loses weight so that the balance of repair and breakdown is upset to the detriment of the former Is the disturbance of balance due to a lessened power of repair or increased breakdown or both of these? A lessened power of repair has already been shown to be in part responsible for the change The animals used were cats and the nerves were cut on the left side Samples of blood were collected and analysed, the controls being taken from the undenervated side The authors made eight determinations on the oxygen use of denervated muscles on one side of the body and of the undenervated muscles on the opposite side In all cases a much greater oxygen use per gramme per minute was found to be present in the denervated muscles It is concluded from this that the atrophy of denervated muscles is not solely due to a decreased power of repair, the breakdown remaining constant, but that it must be due chiefly to an increase in the rate of breakdown of the muscle substance

Quarterly Journal of Experimental Physiology Edited by E A Schafer, W D Halliburton, C S Sherrington, E H Starling, and A D Waller. Vol X, Nos 3 and 4 London Charles Griffin and Co, Limited 1917 Pp 203–401. Price 15*s* —Almost the whole of the text is taken up with an elaborate note on the Parathyroids—Tetania Parathyreopriva its Nature, Cause, and Relations to Idiopathic Tetany It is divided into eight parts Part I, by D Noël Paton and Leonard Findlay, after an introduction on idiopathic tetany and experimental tetany, deals with general methods and symptoms Part II, by D Noël Paton, Leonard Findlay, and Alexander Watson, deals with the Parts of the Central Nervous System Involved and treats successively of the cerebral and cerebellar arcs and the spinal arc and its efferent spinal neurons The authors find from their experiments on cats and dogs that—

1 The nervous symptoms are due to the condition of the central nervous system 2 In the production of the spasticity, tremors, and jerkings the cerebral arc is not directly involved The increased violence of these symptoms after decerebration is due to unopposed action of cerebellar and spinal arcs 3 The tremors and jerkings develop independently of the cerebellar arc, but the integrity of this arc is essential for the production of the sustained spastic tone 4 The integrity of the spinal arc is not essential for the development of the tremors and jerkings, since they persist after section of the dorsal roots of the spinal nerves The efferent neurons are the structures primarily implicated 5 In advanced cases of tetania parathyreopriva disturbances of equilibrium seem to indicate a secondary involvement of the cerebellum 6 In such advanced cases the onset of epileptiform convulsions probably indicates the secondary involvement of the motor part of the cortex cerebri

Part III is by the same authors and deals with the Changes in the Peripheral Nerves and in the Muscles This contribution runs to over 70 pages The methods used and the results obtained in testing the electrical excitability of nerve and muscle are fully described In the normal animal the method of determining the electrical excitability (E E) of nerve and muscle by the application of the electrode on the skin over the structure to be stimulated gives a fairly accurate and consistent method of estimating the E E in milliampères As to tetania parathyreopriva and idiopathic tetany the following are some of the authors' conclusions —

1 As shown by previous workers, any marked decrease in the amount of parathyroid tissue is followed by a very marked increase in the E E of the peripheral motor nerves The same is found in all cases of idiopathic tetany 2. As a rule, no alteration of the normal sequence of the various responses results, but the A.O C is more frequently than in health greater than A.C C and on occasions may equal or be greater than K.C C This is, however, of no diagnostic value 3 Mechanical excitability, so characteristic of idiopathic tetany, is not in our experience such a prominent feature of tetania parathyreopriva 4 The increased E.E of the peripheral nerve is independent of changes in the central nervous system It occurs after section of the nerve and persists till degeneration sets in whether the nerve be cut before with, or after the removal of the parathyroids 5 The E E of muscle to direct stimulation is increased after parathyroidectomy, although not generally to the same extent as that of the nerve 6 This is chiefly due to an increased E.E of the neural structures in the muscle In some cases there is evidence that a post-neural substance may have its excitability increased 7 The nerve-ending is the part of the neural element acted upon, since in cross circulation experiments the results of stimulation of the sciatic nerve bathed in the animal's own blood varies with the changes produced in the peripheral nerve supplied with the foreign blood 8 In tetania parathyreopriva the increased E.E of the peripheral motor neuron is not proportionate to the intensity of the symptoms due to the condition of the central nervous system and after a definite fit it may be markedly reduced In idiopathic tetany the relation is somewhat closer, but is not directly proportionate Hence the increased electrical excitability cannot be taken as a measure of the severity of the condition

Part IV the Etiology of the Condition and its Relationship to Guanidine and Methyl guanidine Intoxication, is by D Noël Paton and Leonard Findlay The various possibilities as to the way in which removal of the parathyroids induces the characteristic train of symptoms are first considered A comparison of the symptoms of guanidine poisoning with those of tetania parathyreopriva shows a very close correspondence They bear the same relationship to tetania parathyreopriva that those following the administration of diphtheria toxin bear to the symptoms of true diphtheria The conclusions arrived at are as follows —

1 There is no direct interrelationship between the parathyroids and the thyroids 2 There is no evidence that the parathyroids exercise a direct controlling influence on the central nervous system 3 The symptoms of tetania parathyreopriva are not primarily due to decrease in any constituent of the body—e g , calcium ions 4 The symptoms are not due to an increase in ammonia or xanthin or β iminazolylethylamine in the blood 5 The symptoms are identical with those produced by the administration of salts of guanidine and methyl guanidine Direct evidence of the increase of these substances in the blood is given in the next paper

Part V , Guanidine and Methyl Guanidine in the Blood and Urine in Tetania Parathyreopriva and in the Urine of Idiopathic Tetany, by David Burns and J. S Sharpe Up to the present no estimations of the amount of guanidine or of methyl guanidine in blood of normal animals have been recorded Small quantities of both are known to occur in human urine The amount of these bases in the urine is greatly increased in animals killed by anaphylactic shock or by burning The methods used are fully recorded The authors' results are summarised in the following table —

Guanidine (and the Methyl guanidine expressed as Guanidine) in mg per 1000 c c

	Dogs	
A BLOOD	Normal (average of 5) 1 0	Parathyroidectomy (average of 8) 8 7
	Dogs	
B URINE.	0·25 (average of 6)	1 1 (average of 6)
	Children	
	(Average of 5 individuals) 8 analyses 0 12	Idiopathic tetany (average of 3 cases) 13 analyses
		Active tetany 0 58
		Latent tetany 0 38
		Recovery from tetany 0 12

There is a marked increase in the amount of guanidine and methyl guanidine in the blood and urine of dogs after removal of the parathyroids and in the urine of children suffering from idiopathic tetany Part VI , The Action of the Blood Serum of Animals in Tetania Parathyreopriva on the Skeletal Muscles of the Frog, by George M Wishart In certain cases the serum of parathyroidectomised dogs and cats acts upon the muscles of the frog in the same way as do dilute solutions of guanidine or methyl guanidine But the variations in the susceptibility of the muscles of different frogs render this biological test unreliable Part VII A Comparison of the Influence on the Protein Metabolism of Parathyroidectomy and of the Administration of Guanidine, by David Burns From his experiments the author concludes that the close similarity in the metabolic disturbances induced in the dog by removal of the parathyroid glands and by the administration of a salt of guanidine to a fasting animal supports the evidence already adduced in the previous parts that these two states are identical Part VIII The Functions of the Parathyroids and the Relationship of Tetania Parathyreopriva to Idiopathic Tetany, by D Noël Paton and Leonard Findlay Reviewing the previous work and their own, the authors conclude that the parathyroids regulate the metabolism of guanidine in the body By doing so they probably exercise a controlling influence on the tone of the muscles Tetania parathyreopriva and idiopathic tetany are identical as regards their characters and metabolism, and although the histological evidence is not conclusive, in all probability the parathyroids are implicated in the latter as in the former

The Veterinary Review Vol I , No 3 August 1917 London and Edinburgh Green and Son Price 3s 6d quarterly —In the *Veterinary Review* for August the editor Dr O Charnock Bradley, has again put before the scientific reader a complete digest of all matters which concern the welfare of the animal world as regards its relation to medicine and surgery It contains summaries of articles written in all civilised countries by numerous authors both medical and veterinary and an original article on "The Transmission of Animal Trypanosomiasis in Northern Rhodesia by Blood sucking Flies other than *Glossina*," by Captain Frederick Chambers F R C V S A V C To the busy scientific man, whether engaged in laboratory or purely clinical work, a digest of this kind is of the greatest value, enabling him to keep in touch with all advances

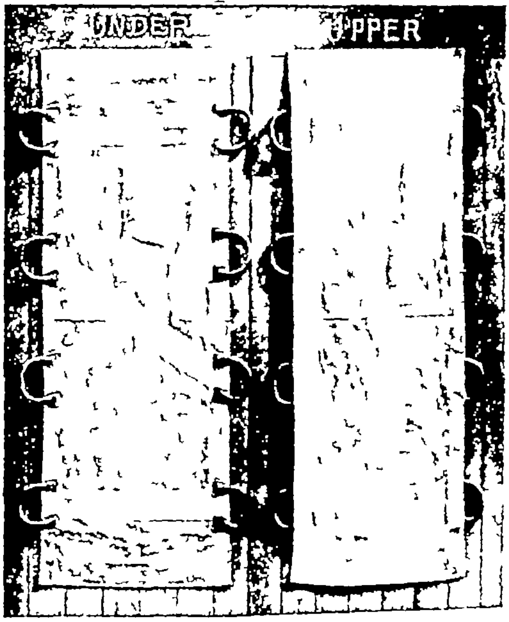
New Inventions.

DEVICES FOR MOVING PATIENTS

A DESCRIPTION is given below of two little inventions I have adopted for the use of military patients here, with gratifying results

1 *Carrying device* —The canvas (Fig 1) is passed under the patient and two nurses, orderlies, or porters on each side take hold of two handles each At the word "Lift" the patient is lifted bodily on to the wheeled stretcher, taken to the theatre, and lifted on to the table After the operation he is carried back in a similar way The canvas is removed before he comes out of his anæsthesia and it is put under the next case for operation In this hospital, where we have over 500 wounded, I find a stretcher for each ward is enough The village saddler makes them for 6s 6d When not in use they are hung by one handle across the anæsthetic room It is possible to move a patient, however badly wounded, from the bed to the operating table and back again without any handling of his person, hence saving pain, &c

FIG 1



The carrying device.

2 *The trolley* —The ends of the beds have no castors The bed end is raised, the trolley put in position under the end of the bed, and the two feet of the bed drop into the cavities in the trolley, as shown in Fig 2 When the bed reaches the desired position the end is raised the trolley kicked out of position and used for the next case The trolley can be wheeled anywhere provided the wheels do not sink into the soil with the weight of the bed The cost wheels included, is 3s 9d With few exceptions we wheel every bed into the balconies or grounds for all bedridden cases early in the morning, and at sundown they are wheeled back The time occupied for this is on the average 40 minutes One trolley is supplied to each ward of 30 beds.

Military Hospital Stepping Hill Hazel Grove near Stockport

"Semprolin" Emulsion

with Iron

THIS preparation admits the administration of iron *for long periods* without digestive disturbance or constipation. The iron being in colloid form is quickly and easily assimilated. With Liquid Paraffin no habit is induced as with purgatives such as cascara aloin, &c. Gives excellent results in Anæmia, &c.

In 8 oz and 16-oz Bottles

CONTAINING

Dialysed Iron	**20 minims**
Russian Liquid Paraffin, B P	**55%**

in each tablespoonful

Samples Free to MEDICAL MEN

ADRENALINE CLIN

(HYDROCHLORIDE)

ADRENALINE CLIN crystallized, chemically pure, corresponds to the formula C $H_{13}NO_3$ (according to Furth, Stolz, Jowet and Bertrand) It presents all the properties that characterise substances of definite chemical composition so that it is possessed of maximum activity and absolute uniformity of physiological action and therapeutical effects.

SOLUTION of ADRENALINE CLIN 1 in 1000 In phials of 5 and 30 c c.
COLLYRIUM of ADRENALINE CLIN 1 in 5000 and 1 in 1000 Drop bulbs of 10 c.c.
Combinations COLLYRIA CLIN Adrenaline-Cocaina and Adrenaline-Eserine.
GRANULES of ADRENALINE CLIN 1/4 milligramme each (1/255 grain)
SUPPOSITORIES of ADRENALINE CLIN 1/2 milligramme each (1/128 grain)
CLIN STERILISED TUBES of 1 c.c. for **hypodermic injection.**
ADRENALINE (hydrochloride) alone 1/2 and 1/10 mg per c.c. (Box of 10 tubes.)
ADRENALINE in combination (COCAINE, STOVAINE, ALYPINE) in boxes containing 6 or 12 tubes.

ENESOL

(SALICYLARSINATE of MERCURY)

AN IDEAL COMPOUND FOR COMBINED ARSENO-MERCURIAL TREATMENT OF SYPHILIS.

Superior to all others on account of:

1. **Its slight Toxicity,** rendering possible the administration of comparatively large doses of mercury and arsenic without setting up intolerance 2. **Injections Painless** even in full doses Never causes irritation

3 **Double specific action** (mercurial and arsenical)

4 **Pharmacology and Doses.—Tubes of 2 c.c. and 5 c.c.,** containing 3 cgr (0 46 grain) per c.c. solution

Medium Dose.—Intramuscular injections of 2 c c. corresponding to 6 cgr (0 92 grain) of **Enesol** per day should be injected by preference in the gluteal region

Large doses or saturated solutions.—Intramuscular injections of 4 to 6 c c corresponding to 12 to 18 cgr (1 85 to 2 77 grains) of **Enesol** every two or three days Intravenous injections of 2 c c to 10 c c corresponding to 6 to 30 cgr (0 92 to 4 63 grains) of **Enesol,** according to the subject, urgency and gravity of the case every two or three days

Sold only in Boxes of 10 tubes of 2 c c each and 6 tubes of 5 c c each

LONDON SATURDAY SEPTEMBER 22, 1917

Losses and Compensations

SOMETHING used to be heard of the ease and safety of the doctor's duties in the field, whether by land or sea, compared with those of his fellow officers in one of the combatant services. Such expressions grew rare during the South African War, and now are heard no more. The appearance with a terrible regularity of obituary notices of doctors, many of them at the commencement of promising careers, who have been instantly killed as they tended the wounded in advanced posts, who have been drowned in naval engagements or in torpedoed hospital ships, or who have died of injuries and diseases incidental to campaigning, has opened the eyes of everyone to the risks run by the medical officer on active naval or military service. In administrative posts, again, the medical work is often excessively onerous, for on the constant watchfulness and care of the responsible officer and on the maintenance of a *high* standard of efficiency, depend the lives and the chances of restoration of countless numbers of men of all ranks. It is only right that for such services honours should be given, and in the *record* of the London medical schools for the third completed year of warfare is contained the evidence that the debt of the country in this way is being steadily paid. More than 150 holders of the Military Cross appear in this incomplete list of London schools alone, along with other still more coveted distinctions, while the total of Commanderships of many noble Orders is not much fewer. The figures from Scotland, Ireland, and the provinces tell a like tale of duty done and guerdon won.

This is one side of a picture on which it is justifiable for the profession of medicine to look with pride. But there is another *side*, and the attention of medical men requires no directing to it; it is always present, consciously or subconsciously, to the mind of the doctor on service. What is becoming of his practice? What will remain of it when he returns? What will become of him if disabled, and of those dependent on him if he is killed? And the anxiety has not been rendered less by the extreme uncertainty which has prevailed until recently in regard to what the State is prepared to do in compensation for the losses entailed in its service, and how other needs are to be met for which the State disclaims responsibility. The *draft* of the new Royal Warrant issued a week or two ago by the Ministry of Pensions now makes it clear enough what the officer can expect from the State on account of personal disablement, and, in case he loses his life, for the maintenance of his widow and the education of his children. To many whose personal needs have been small and their establishments simple the State aid, which comes to them as their right and in recognition of services rendered, should not prove inadequate. But in many other cases this will not be so, and the man whose only asset before the war consisted of a good education and a hopeful prospect may well have grave doubts for the future of his wife and young children if he is taken from them or left disabled. Yet provision for them is indeed his right. It is not a question of charity but of justice, and it is to this category that many of the Army medical officers belong. The lack is pressingly felt of a patriotic fund including the whole medical profession to make automatic provision for all cases of hardship. Financial success in medicine is a lottery in which prizes are not won by all the deserving, but a percentage levy on the actual income of each medical man, whatever his position, would suffice to insure all its members against the risks of death and disablement before success is theirs. The Royal Medical Benevolent Fund in times of peace has long attempted to meet this need on a voluntary basis although its means have never been sufficient to do so completely. It is appropriate for the same organisation to deal with war emergencies, keeping the money to be raised for this purpose strictly separate from the main Fund. We have already given publicity to this special War Emergency Fund, directing attention to the desire of its promoters that it shall supplement and fill in the gaps left by other agencies without competing with them or covering any of the same ground.

Death and disablement with the consequent need of support for the widow and educational facilities for the orphans are more tangible objects for relief than the loss of professional earnings from a practice which has inevitably dwindled during absence on service. Where the drop has been greatest it can still, doubtless, be made good within some period after the practitioner's return in full vigour of mind and body, but in the mean time he will have many out-goings and little or no in-comings, and in some cases will be involved in a heavy uphill struggle. No fund quite meets his case. The Loan Fund proposed by the British Medical Association was intended for this purpose, but a wise decision of the recent Annual Representative Meeting deferred its definite institution until it has been shown that the needs cannot be met by the amalgamation or coöperation of other funds. In another column we have set out with some detail the nature and scope of these other funds, beginning with the Civil Liabilities Committee, which deals with non-commissioned applicants, leading on to the Professional Classes War Relief Council, whose work has been of surpassing value to many of those whose burdens have been borne in silence. The work of the Officers Families Fund has in the aggregate been very large, but its field of action is also very large, and it naturally deals only in small proportion with the needs of the medical services. The Officers' Benevolent Branch of the Auxiliary

THE TREATMENT OF VENEREAL DISEASES.

Recurrent Fever
SYPHILIS

GALYL

Framboesia
Sleeping Sickness

GALYL is as effective as SALVARSAN or NEOSALVARSAN on Spirochætes and Trypanosomes, more rapid in action, and free from the neurotropic and congestive action of these preparations

FOR INTRAVENOUS INJECTIONS — (Fig 1)

(1) DILUTE.—GALYL is supplied in neutral glass ampoules containing the necessary dose of Sodium Carbonate, sterile distilled water only being used for the dissolution.

(2) CONCENTRATED — A special outfit containing one dose GALYL, one ampoule sterilised solution and one small filter is supplied.

DOSES
0·10—0 15—0·20—0·25—0·30
0 35—0·40

(3) FOR INTRAMUSCULAR INJECTIONS — (Fig 2)

GALYL is supplied in glucose solution.

DOSES
0 10—0 15—0·20—0 30.

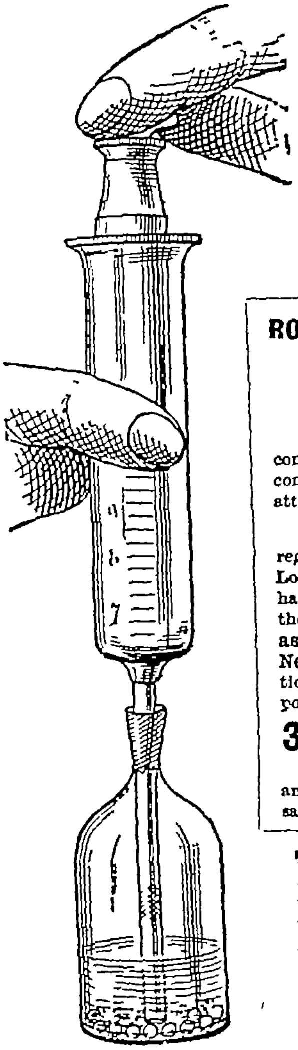

Fig 1.

ROYAL COMMISSION ON VENEREAL DISEASES.

Final Report of the Commissioners

SUBSTITUTES FOR SALVARSAN

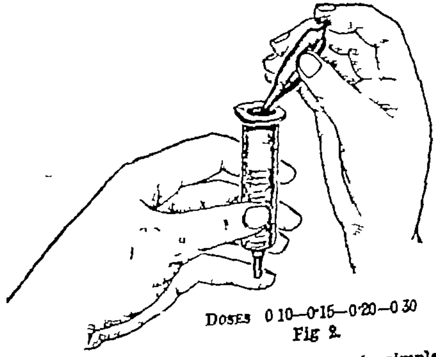
another French substitute GALYL a compound of arsenic and phosphorus has recently come into prominence and its use has been attended with considerable success

'Favourable reports have also been obtained regarding the preparation GALYL. At the Male Lock Hospital 1000 injections of this substance have been administered, and it is reported that they have been attended with **as good results as in the cases treated by Salvarsan and Neosalvarsan**, in no instance were the injections followed by reactions indicative of arsenic poisoning

3000 injections (intravenous) were given in one of our **Service Hospitals**.

' No case has given the slightest cause for anxiety and the clinical results are very satisfactory *Staff Surgeon s Report*

" .. .. Intramuscular Galyl with a little care in technique, can be used with little or no pain. The results are excellent, both immediate in the clearing up of evident lesions and ultimate, as proved by the Wassermann test. Personally I have used this preparation in over 400 injections with the best results and without the slightest mishap or inconvenience to the patient.
Yours faithfully Dr ——"



DOSES 0 10—0·15—0·20—0 30
Fig 2.

The technique is simple.

Fig 2 shows the ampoule of Galyl being emptied into the syringe barrel—the needle is now fixed on the neck of the syringe and the plunger inserted into the barrel. The injection is then ready for administration

CUPRASE

FOR THE MEDICAL TREATMENT OF CANCER.

Clinical facts carry greater weight than theoretical deductions Doctors of repute in various countries give cases of great variety In all of these **pain has been eliminated**, and in a good percentage **cures are claimed** in no instance **any undesirable effects** It should be remarked that all or nearly all the observations refer to inoperable cases in which the prognosis was unfavourable at an early date It is needless to emphasize the practical importance of a preparation capable of yielding such results even relative in the worst stages of a disease which has always been regarded as absolutely resisting the action of all internal remedies

Nothing has been found which can compare with the effects produced by means of Cuprase

Its **easy application** (subcutaneous injections) places it within the reach of all practitioners **It is not toxic**

Cuprase is a colloidal Copper hydroxide obtained by the reduction of Salts of Copper in the presence of Albumosic Acid

Disappearance of the Pain.

Return of Sleep

Increase of the Appetite,

Colour and Strength.

WARWICKSHIRE, July 1st, 1917

DEAR SIRS —Will you please send me another box of Cuprase ampoules. The previous lot effected a most remarkable cure in an elderly lady suffering from cervical cancer — the cauliflower like growth has disappeared with its offensive discharge.

This case was given three months life by a specialist, being inoperable

Yours faithfully
(Signed)

insufficient diet and the use of the so called "food substitutes There is a great scarcity of milk and dysenteric patients are often unable to obtain this essential article of their diet When obtainable the fatty matter has already been abstracted from the milk by order of the Government for use in munitions works There appears to be a possibility that before long relapsing or famine fever will be added to the epidemic diseases current in the Central Empires Already cases are being reported weekly in some districts of Germany, and Mannheim is specially mentioned as one of the worst sufferers In Poland relapsing fever is also occurring, and cases in increasing numbers are being reported week by week, especially in the towns of Warsaw, Lodz, and Plock, where the Poles are experiencing great privations and where the various epidemics have been adversely affected by the absence of medical men

Annotations.

"Ne quid nimis."

THE ESTIMATION OF FILTRATE-NITROGEN IN BLOOD AND OTHER BODY-FLUIDS

Mr R Donald, B Sc., is publishing in the *Quarterly Journal of Medicine* the results of a careful investigation into the methods for estimating filtrate nitrogen in the blood and other body fluids The research was made at the Pathological Institute and the Clinical Laboratory, London Hospital It is obvious that an estimate of nitrogenous waste in the blood might prove a valuable aid to diagnosis and therefore to treatment The work was done in the course of an inquiry into the retained nitrogen in various substances, principally blood and cerebro spinal fluid obtained in the wards and post-mortem room of the hospital The method consists in precipitating the proteins centrifuging instead of filtering, and then testing the clear fluid by an efficient hypobromite process The proteins are eliminated in two simple rapid stages First, the blood in a centrifuge tube is mixed with its own volume of a saturated sodium chloride solution in 6 per cent. sulphuric acid or in a mixture of nine tenths of 6 per cent sulphuric acid and one tenth of 6 per cent phosphoric acid The use of brine containing phosphoric acid avoids the precipitation of ammonia by phosphomolybdic acid, while it is compatible with phosphotungstic acid. After two centrifugations a clear liquid is obtained ready for treatment in the ureometer Ammonia and creatinin are included in the filtrate-nitrogen, ammonia being the direct representative of urea the inclusion of its nitrogen is desirable By this method it is stated that a provisional reading can be reported within about 20 minutes of the time the blood was received but for accuracy another half hour is required. The particular method of employing the ureometer for the purpose is fully described in the paper It depends upon the decomposition of the urea, creatinin and ammonia by hypobromite into free nitrogen gas. Control experiments done with various small known amounts of urea and of ammonium chloride showed that the process is quite close enough for clinical purposes According to the author, the normal lowness of the filtrate nitrogen in the blood seems to depend on three factors (1) A sufficiency of healthy kidney tissue (2) a sufficiently maintained or compensated circulation of blood through the kidneys, (3) a sufficient supply of water to the blood to allow a normal excretion of urine through free passages In children factors (1) and (2) are usually so good that their health percentage of filtrate nitrogen seems smaller than the 0 035 per cent of filtrate nitrogen stated as the general health limit Finding, he adds, in the blood taken at the autopsy of a baby admitted dying of diarrhœa and vomiting, but not yet emaciated some 0 18 per cent of filtrate nitrogen "is like hearing a post-mortem echo of the cry of the child's system for water ' Finally, such subimbibitional hypernitræmia will he concludes, be allowed for by an observant medical attendant As for factor (2), the "heart kidney seems to maintain the excretory function wonderfully well, but when factors (1) and (2) coöperate in failure, as, for instance, when with insufficient kidney tissue the circulation fails, then the filtrate nitrogen may rise to 0·2 per cent and higher, much as in acute nephritis with increased blood pressure The test described may prove valuable, adding to the objective data for the clinician s skill to work on The details of manipulation and the requisite apparatus are clearly described

INCIPIENT SCURVY

PROBABLY the most common error of diagnosis is failure to recognise a disease in its earlier stages To some extent this is unavoidable, a certain degree of development of symptoms is necessary for diagnosis But errors are constantly occurring from want of knowledge of the early stages of disease With very few exceptions (such as pulmonary tuberculosis) these have not been systematically studied The text books describe almost solely the well developed clinical picture, and if here and there an early symptom be mentioned no attempt is made to sketch the disease as a whole at an early stage, and in the section on diagnosis only the fully developed disease is considered In the *Cleveland Medical Journal* for August Dr J M Miller has suggested how infantile scurvy may be recognised at a stage previous to the development of the well known symptoms His attention was first drawn to the existence of this stage by the following case A child, aged 18 months had been ailing for several weeks with fretfulness, loss of appetite and sleep, failure to gain weight, and slight irregular fever These symptoms were attributed to teething, but no teeth were erupting No digestive disturbances were apparent, nor could evidence of tenderness on moving be discovered, unless fretfulness on being disturbed could be so explained The knee jerks were exaggerated Careful examination of the gums showed them to be perhaps a little dusky, but there was no bleeding or sponginess and no petechiæ The infant was taking a high grade commercially pasteurised milk with a proprietary preparation of dextro maltose This preparation was stopped and orange juice and potato given In a week the child was well, thus indicating the scorbutic nature of the complaint In another case a child of 12 months had but one symptom crying as if in pain when rolled over on the left side but firm pressure over the upper part of the left thigh seemed also to give pain. Careful search failed to show anything else The infant was exceptionally robust It was found on inquiry that the mother was pasteurising the already commercially pasteurised milk Fresh milk and orange juice were given, R A M C Funds has not yet existed long enough to command the support essential to its complete success The War Emergency Fund of the Royal Medical Benevolent Fund proposes to take cognisance of the work of all these agencies, and to test their application in each several case by personal inquiry on the part of a single member of its staff The inquiry officer, who will be pledged to secrecy, will then lay an anonymous case before the executive committee of the Fund An immediate and adequate response to the appeal for the successful carrying out of the scheme will certainly go far to lighten the burden of many a medical man now on service, and will do so in a way removed as far as possible from an act of charity We commend the War Emergency Fund of the Royal Medical Benevolent Fund again to the consideration of the medical profession and to the generosity of the general public

◆

Current Epidemics in the Central Empires

Medical science during the present war has succeeded in preventing the occurrence among the military of certain epidemic diseases which in former campaigns have ravaged the forces in the field But among the civil populations of the Central Empires and among the unfortunate inhabitants of the occupied territories it is otherwise At the present time small pox, typhus, and dysentery are very prevalent, and relapsing fever is threatening to add itself to the list For more than two years small pox has been epidemic in Austria, and more particularly in the provinces of Galicia and Bukowina Not far short of 50,000 small pox cases have been reported in Austria during 1915–16, more than 42,000 of the attacks occurring in these two provinces, whence the infection was carried to some of the larger cities, including Vienna, Prague, and Budapest In Vienna during the 12 months immediately following the outbreak of war over 1600 cases were reported As vaccination is not obligatory in the civil population of Austria many persons are unprotected against small pox infection In Poland the disease is visiting Warsaw, among other places

Germany is regarded as being the best prepared of all European countries to resist attack by small pox, but the disease has been epidemic in North Germany during the first seven months of 1917, 2400 cases having been notified to the authorities, the largest number yet recorded in Germany since notification was begun The prevalence began in December, 1916, at Hamburg, where Russian prisoners were being employed as dock labourers and by whom probably the infection was introduced In addition to the prisoners of war large numbers of the people of the occupied districts of Belgium, Northern France, Poland, and other Russian provinces have been deported from their homes and compelled to work in North Germany in the fields or in the mines and factories or in other industries These wretched slaves, coming from countries in which vaccination is not compulsory, are in many instances unprotected against small pox, and form susceptible material on which an epidemic could easily develop Their susceptibility to infection is not likely to have been diminished by the overcrowding, underfeeding, and the overworking to which they have been subjected, nor by the depression of spirits from which they have suffered during their bondage From Hamburg small pox spread in the early months of 1917 to other districts in North Germany, affecting also some of the large towns, including Berlin, Munich, Leipzig, Potsdam, Essen, Bremen, Altona, Kiel, and Lübeck Small pox is in Europe generally a disease of the winter and spring months, so that while there has been in August some diminution in the number of cases reported weekly, it is very probable that with the advent of winter we may see a recrudescence of the epidemic in Germany

Typhus is endemic in the Austrian province of Galicia, but since the outbreak of war it is probable that typhus infection has been brought into the Austrian war zones by prisoners from Russia and Serbia It is well known that the wretched Serbian prisoners interned in Austria since the war have died in thousands from typhus in the concentration camps Among the Austrian civilian population more than 13,000 typhus cases occurred during 1915, and over 12,000 in 1916 During the first three months of 1917 about 3000 fresh cases were notified, most of them in Galicia. In Hungary, typhus is now prevalent, and in the first half of 1917 some 2500 cases were reported In Bosnia and Herzegowina typhus has also been rife during the whole period of the war In Poland, now occupied by German troops, there is at the present time a very severe epidemic of typhus going on, especially in the city of Warsaw and in the adjoining districts During the last 12 months nearly 16,000 cases have been reported, of which more than 8500 occurred in Warsaw Typhus has been appearing in Germany since 1914, chiefly among the prisoners of war who, crowded together in large numbers in camps, with little means afforded them of maintaining personal cleanliness or opportunities for changing their clothes and keeping themselves free from body vermin, soon developed typhus of a virulent kind, probably infected in the first instance by Russians

Dysentery is epidemic in Germany, and especially in Prussia, where in the first seven months of 1917 about 13,000 cases were notified among the civil population, more than 6000 attacks being reported during the last fortnight The chief places at present affected are Berlin, Potsdam, Strasburg, Frankfort, Munich, Mannheim, and the industrial districts of Rhenish Westphalia In Austria, too, dysentery is epidemic and from February to July, 1917, more than 4000 cases were officially recorded A Vienna newspaper recently stated that "cholera itself could not be worse than the dysentery epidemic now raging" This paper also asserted that the disease had been brought to Vienna by soldiers from the front There is suggestion that these prevalences of dysentery in Germany and Austria are associated with malnutrition, arising partly from improper or insufficient diet and the use of the so called "food substitutes" There is a great scarcity of milk and dysenteric patients are often unable to obtain this essential article of their diet When obtainable the fatty matter has already been abstracted from the milk by order of the Government for use in munitions works There appears to be a possibility that before long relapsing, or famine, fever will be added to the epidemic diseases current in the Central Empires Already cases are being reported weekly in some districts of Germany, and Mannheim is specially mentioned as one of the worst sufferers In Poland relapsing fever is also occurring, and cases in increasing numbers are being reported week by week, especially in the towns of Warsaw, Lodz, and Plock, where the Poles are experiencing great privations and where the various epidemics have been adversely affected by the absence of medical men

Annotations.

"Ne quid nimis"

THE ESTIMATION OF FILTRATE-NITROGEN IN BLOOD AND OTHER BODY-FLUIDS

Mr R Donald, B Sc, is publishing in the *Quarterly Journal of Medicine* the results of a careful investigation into the methods for estimating filtrate nitrogen in the blood and other body fluids The research was made at the Pathological Institute and the Clinical Laboratory, London Hospital It is obvious that an estimate of nitrogenous waste in the blood might prove a valuable aid to diagnosis and therefore to treatment The work was done in the course of an inquiry into the retained nitrogen in various substances, principally blood and cerebro spinal fluid obtained in the wards and post mortem room of the hospital The method consists in precipitating the proteins, centrifuging instead of filtering, and then testing the clear fluid by an efficient hypobromite process The proteins are eliminated in two simple rapid stages First, the blood in a centrifuge tube is mixed with its own volume of a saturated sodium chloride solution in 6 per cent sulphuric acid or in a mixture of nine tenths of 6 per cent sulphuric acid and one tenth of 6 per cent phosphoric acid The use of brine containing phosphoric acid avoids the precipitation of ammonia by phosphomolybdic acid, while it is compatible with phosphotungsic acid After two centrifugations a clear liquid is obtained ready for treatment in the ureometer Ammonia and creatinin are included in the filtrate nitrogen, ammonia being the direct representative of urea the inclusion of its nitrogen is desirable By this method it is stated that a provisional reading can be reported within about 20 minutes of the time the blood was received, but for accuracy another half hour is required. The particular method of employing the ureometer for the purpose is fully described in the paper It depends upon the decomposition of the urea, creatinin and ammonia by hypobromite into free nitrogen gas Control experiments done with various small known amounts of urea and of ammonium chloride showed that the process is quite close enough for clinical purposes According to the author, the normal lowness of the filtrate nitrogen in the blood seems to depend on three factors (1) A sufficiency of healthy kidney tissue, (2) a sufficiently maintained or compensated circulation of blood through the kidneys, (3) a sufficient supply of water to the blood to allow a normal excretion of urine through free passages In children factors (1) and (2) are usually so good that their health percentage of filtrate nitrogen seems smaller than the 0 035 per cent of filtrate nitrogen stated as the general health limit Finding, he adds, in the blood taken at the autopsy of a baby admitted dying of diarrhœa and vomiting, but not yet emaciated, some 0 18 per cent of filtrate nitrogen "is like hearing a post mortem echo of the cry of the child s system for water" Finally, such subimbibitional hypernitræmia will he concludes, be allowed for by an observant medical attendant As for factor (2), the "heart kidney" seems to maintain the excretory function wonderfully well, but when factors (1) and (2) coöperate in failure, as, for instance, when with insufficient kidney tissue the circulation fails, then the filtrate nitrogen may rise to 0 2 per cent and higher, much as in acute nephritis with increased blood pressure The test described may prove valuable, adding to the objective data for the clinician's skill to work on The details of manipulation and the requisite apparatus are clearly described

INCIPIENT SCURVY

PROBABLY the most common error of diagnosis is failure to recognise a disease in its earlier stages To some extent this is unavoidable, a certain degree of development of symptoms is necessary for diagnosis But errors are constantly occurring from want of knowledge of the early stages of disease With very few exceptions (such as pulmonary tuberculosis) these have not been systematically studied The text books describe almost solely the well developed clinical picture, and if here and there an early symptom be mentioned no attempt is made to sketch the disease as a whole at an early stage, and in the section on diagnosis only the fully developed disease is considered In the *Cleveland Medical Journal* for August Dr J M Miller has suggested how infantile scurvy may be recognised at a stage previous to the development of the well known symptoms His attention was first drawn to the existence of this stage by the following case A child, aged 18 months, had been ailing for several weeks with fretfulness, loss of appetite and sleep, failure to gain weight, and slight irregular fever These symptoms were attributed to teething, but no teeth were erupting No digestive disturbances were apparent, nor could evidence of tenderness on moving be discovered, unless fretfulness on being disturbed could be so explained The knee jerks were exaggerated Careful examination of the gums showed them to be perhaps a little dusky, but there was no bleeding or sponginess and no petechiæ The infant was taking a high grade commercially pasteurised milk with a proprietary preparation of dextro maltose This preparation was stopped and orange juice and potato given In a week the child was well, thus indicating the scorbutic nature of the complaint In another case a child of 12 months had but one symptom, crying as if in pain when rolled over on the left side, but firm pressure over the upper part of the left thigh seemed also to give pain Careful search failed to show anything else The infant was exceptionally robust It was found on inquiry that the mother was pasteurising the already commercially pasteurised milk Fresh milk and orange juice were given, and the symptoms disappeared in a few days In a third case an infant, aged 9 months, had been fed on a milk prepared with peptogenic milk powder, upon which it had thriven. From the beginning of the eighth month it had ceased to gain weight, becoming fretful, with loss of appetite and sleep These symptoms were attributed to teething, although no teeth were present. The only suggestive sign was some œdema of the lower limbs and perhaps slight pain on deep pressure over the spines of the tibiæ Orange juice and fresh milk were given and the powder discarded In a week all symptoms had disappeared In a fourth case a child of 10 months was fed on a proprietary dextro maltose preparation and pasteurised milk, on which it did well up to 8½ months From this time it ceased to gain weight, or gained only slightly Anorexia then ensued, only half the amount of food being taken For two or three weeks there had been slight fever (100 5°F at night), with fretfulness and sleeplessness As usual, the symptoms were attributed to teething, and two upper incisors were erupting Careful examination revealed only slight exaggeration of the knee jerks On stopping the malt food and giving fresh milk and orange juice the infant's condition quickly became normal Not one of these infants showed the classical picture of scurvy Indeed, two of them would have been impossible to class as such but for the therapeutic test This form of scurvy has been described also by an American writer, Alfred F Hess, as "latent scurvy," characterised by stationary weight, pallor, anorexia, and general want of well being, quickly disappearing under antiscorbutic treatment No doubt, as Dr Miller remarks, it is not uncommon, although not generally recognised It then either ends in spontaneous recovery or progresses to a well defined form Hess has shown that it can be produced by pasteurisation of milk Bi pasteurisation seems to have been a factor in some of the above cases Dr Miller appears to have given a satisfactory explanation of some of the cases labelled "dentition" for want of a better diagnosis

CAMPHOR IN CARDIO-VASCULAR DISEASES

THERAPEUTIC observations by Professor Marfori,[1] of the University of Naples, with regard to the action of camphor on the cardio vascular system, have brought to light certain properties which deserve attention Hitherto this drug has been looked upon as the last resource to prolong the life of a diseased and exhausted heart, and injections of camphorated oil have been almost exclusively reserved for counteracting cardiac collapse in acute infective disorders or the threatened paralysis of the last stages of heart disease Professor Marfori and his assistant, Dr G Leone, found that the isolated mammalian heart, when poisoned by chloral so as to render the pulsations barely perceptible, could be rapidly restored to action by camphor, and furthermore, that its action on the circulation was very characteristic, as it could be proved that small doses invariably caused a diminution of arterial pressure and at the same time increased the volume of the cardiac pulsations Only toxic doses of camphor give rise to increased arterial pressure, accompanied by convulsive phenomena which seem to be independent of the vaso motor centres, as they are observed even during profound narcosis when these centres are rendered inexcitable Hence during the course of chronic myocarditis with simple cardiac insufficiency, changes in rhythm and auricular fibrillation, Professor Marfori considers no other drug can compete with camphor in sustaining the activity of the heart and steadying the pulse. He noticed that the beneficial effects obtained were continued after the drug was suspended, but recommends systematic treatment for a long period by giving one, or two, daily hypodermic injections of 0 10 gramme in oily solution. These doses may also be given by mouth as they are well borne In valvular lesions, when disturbance of the pulmonary circulation and hypertension in the right ventricle predominate, camphor is the most rational and efficacious remedy The drug is also quite useful in the pulmonary sclerosis of tuberculosis and in arterial hypertension with hypertrophied heart, vascular spasm of climacteric origin, and arterio sclerosis, it is capable of inducing beneficial changes in disordered function of the myocardium and especially of the right ventricle In conclusion, Professor Marfori says that camphor must no longer be considered merely as a remedy in the hour of death, but rather as a drug which, when intelligently administered, is capable of producing beneficial results throughout the entire course of various cardiac and vascular diseases owing to its special properties, which are distinct from those of other heart drugs

LEAD POISONING IN CHILDREN

LEAD poisoning in children is a condition which has received little or no attention in this country Many cases have, however, been observed in Australia, and articles which have appeared in the medical journals there from time to time during the last 25 years constitute the important literature of the subject As the symptoms differ somewhat from those in adults, on which all text book descriptions are based, lead poisoning in children is probably often overlooked One way in which Australian children have been poisoned is by contaminating their hands with the dried paint of railings and walls and then sucking their fingers or biting their nails In the *American Journal of the Medical Sciences* Dr K. D *Blackfan*, of Baltimore, has published an important paper on lead poisoning in children and reported four cases In early cases a change in disposition is often the first symptom noticed The child grows fretful, peevish, and often very restless at night The appetite declines, the breath is foul, and frequently hæmorrhages from the gums occur The child may complain of pain in the epigastrium and legs In cases of longer duration the pains in the abdomen become continuous and more severe Constipation is the rule and vomiting is rare The muscles are often so painful as not to permit of the weight of the bedclothes The gait is described as characteristic It is waddling, the patients walk on the outside of the feet, the toes are dragged and with each step the legs are swung sideways before the feet are put to the ground The attention of the parents may be attracted by one or more of these symptoms, but frequently nothing is observed until cerebral manifestations, such as convulsions, occur Very few of the cases show the characteristic wrist drop of adults Paralysis of cranial nerves is usual, the facial and motor oculi, entirely or partly, being most frequently affected Optic neuritis is also common As a rule the temperature is normal, but it may be irregularly elevated In fatal cases, especially in those with cerebral disturbances, it may rise as high as 105° or 106° F before death In early cases the symptoms may be only suggestive Then other evidence, such as the blue line on the gums and stippling of the red corpuscles, may be found Direct evidence of lead poisoning may be obtained by finding the metal in the urine or fæces The following are two of the cases reported by Dr Blackfan A boy, aged 2½ years, on March 8th 1915, had a convulsion from which he recovered On the 12th he was brought to hospital in convulsions which continued for 24 hours They involved the eyes, the left side of the face, and the left arm There were a leucocytosis of 19,000, stippling of the red corpuscles, a lead line on the gums, and an enlarged spleen The fundi were normal and lead was not found in the urine On March 26th convulsions involving the face and left arm recurred They continued for 24 hours, the temperature rose to 107 5°, and he died His father stated that he would gnaw any painted article and that he and his brother had ruined a set of parlour furniture by eating the paint off it In another case a boy, aged 3 years, became drowsy on July 30th, 1915, refused food, and vomited At night he was delirious On August 1st he became comatose and had several convulsions On the next day he was admitted to hospital There was a lead line about several of the upper teeth, and a few of the red corpuscles were stippled He lay in a condition of stupor for two or three days There was a *tache cerébrale* and the neck was rigid. On the 5th he was much better, sat up in bed, and could walk, but there was incomplete paralysis of the right facial nerve By the 12th he had quite recovered The source of the poisoning was not known

---

THE PROTECTIVE FUNCTIONS OF THE SKIN

THE function of the skin as a mechanical protection to the organs which lie within it is so obvious that it may have led to the overlooking of other equally important protective functions The skin as a whole may, of course, be regarded as an organ with a common and complete function of its own, to which view testimony is borne by the complete way in which it suffers in certain infectious diseases, such as scarlatina and variola, and it should be noted that it is precisely these infections in which the skin plays a large part where permanent or nearly lifelong immunity results Professor B Bloch, head of the dermatological clinic in Zürich, discusses some of these immunity problems in relation to the skin in a novel and suggestive way in the *Correspondenz Blatt für Schweizer Aerzte* for August 4th. He notes how seldom general paralysis or tabes is associated with a cutaneous gumma in the same patient and how rare it is to see these late parasyphilides at all in countries where in consequence of defective treatment severe tertiary lesions are common in the skin. He quotes the statistics of Mattauschek and Pilcz to confirm the relative infrequency of tabes in patients with early abundant cutaneous involvement Taken together these and similar observations lead Dr Bloch to lay great stress on the allergic function of the skin, its reaction to an unwelcome intrusion of which it has once had experience The classical researches of Richet, v Pirquet, and Römer have shown how the cutaneous manifestations of tubercle are influenced by this function of allergy which regulates their clinical course as well as the anatomical structure of the tuberculous nodule itself Cutaneous tuberculides are nothing else but the reaction of the forewarned skin of the chronic consumptive to any isolated bacilli brought by the blood stream Historically it has been from studies of the skin—beginning with Jenner's vaccination and Koch's fundamental experiment of tubercle inoculation in the guinea pig—that most light has been thrown on problems of immunity Due in part to the fact that the skin is so favourably situated for exact observation, the fact probably remains that it is to the external covering of the body which we must look for the most important workshop of the immunisation The struggle against attacking microbes from without has slowly adapted the skin and given it the ability to react against the parasites themselves as well as their toxins with the process which we now know as allergic inflammation This function has been gradually acquired in the history of the race and of the individual, since neither the skin of the lower animal nor of the new born child reacts in at all the same way as that of the human adult In this quality Dr Bloch sees one of the most important relations between dermatology and general medicine

THE inaugural address at the London (Royal Free Hospital) School of Medicine for Women, Hunter street, W C, for the session 1917–18 will be delivered by Dr Louisa Garrett Anderson, C B.E, on Monday, Oct 1st, at 3 30 P M, the subject being "Ambition."

WAR SERVICE AND THE MEDICAL MAN PENSIONS, GRANTS, AND ALLOWANCES

WE have put together in concise form the various means through which the medical man, who has entered either the Navy or Army, is compensated for invalidism or loss of professional income, while the case of his death on service is considered in respect of pensions to widows and children. The new Royal Warrant is placed first as it is not merely the most important organisation but is part of the ordinary terms of agreement between employer and employed Various agencies follow applicable in greater or lesser degree in different circumstances and the source of further information if required is given in each case. The War Emergency Fund of the Royal Medical Benevolent Fund is placed last but one, as its intention is avowedly to supplement and fill in the gaps of the other agencies, the Medical Patriotic Fund of the British Medical Association last of all as the fund is only to be instituted if others fail to coöperate or amalgamate.

MINISTRY OF PENSIONS THE ROYAL WARRANT (July, 1917)

Object —The draft Warrant issued by the Minister of Pensions in July deals with the retired pay of disabled officers (naval or military) and with the pensions of the families and relatives of deceased officers, with effect from April 1st, 1917 and the option of further retrospective effect if more favourable to the officer than his present retired pay The actual schedules are given as follows —

(1) *Retired Pay to Disabled Officers*

Degree of disablement	Percentage degree of disablement	Retired pay on account of disablement.										
		Officers not holding permanent commissions in Regular Forces									Officers holding permanent commissions in Regular Forces	
		Major General	Brigadier General		Colonel		Lieutenant Colonel	Major		Captain Lieutenant, or Second Lieutenant		All ranks	
	Per cent	£	£	s	£	s	£	£	s	£	s	£	
1	100	350	325	0	275	0	250	225	0	175	0	100	In addition to retired pay under Royal Warrant of Dec. 1st 1914
2	80	280	260	0	220	0	200	180	0	140	0	80	
3	70	245	227	10	192	10	175	157	10	122	10	70	
4	60	210	195	0	165	0	150	135	0	105	0	60	
5	50	175	162	10	137	10	125	112	10	87	10	50	
6	40	140	130	0	110	0	100	90	0	70	0	40	
7	30	105	97	10	82	10	75	67	10	52	10	30	
8	20	70	65	0	55	0	50	45	0	35	0	20	

(2) *Pensions, Gratuities, and Allowances to Officers' Widows and Children*

Rank	Widow s pension.		Widow's gratuity	Children s allowances	
(1)	(2)	(3)	(4)	(5)	(6)
Field Marshal	£800	£600	£3500	£30	£25
General	600	450	3000	30	25
Lieutenant-General	600	375	2000	30	25
Major General	400	300	1100	30	25
Brigadier General	300	225	900	30	25
*Colonel	200	150	600	24	20
†Lieutenant-Colonel	180	135	450	24	20
Major	140	105	300	24	20
Captain	100	75	250	24	20
Lieutenant	100	75	140	24	20
Second Lieutenant	100	75	100	24	20

* Colonel means an officer who has been employed in the rank of Colonel † Including a Colonel not employed as above

N B —Whether pension is granted to the widow on scale (2) or (3) and whether the gratuity (4) is added, depends on the particular circumstances attending the officer s death, and the same consideration applies to the additional children s allowance (6) Allowances are continued up to the age of 18 in the case of sons (with extension for purposes of education or apprenticeship) and to the age of 21 in the case of daughters

Conditions —Retired pay at temporary rates is given until disablement has reached its final condition, and a permanent pension then awarded cannot be subsequently altered to the officer's disadvantage *During special treatment pay at the* highest degree of disablement may be received In the case of total disablement the officer requiring the constant attendance of a second person may receive an additional allowance of £78 a year When the degree of disablement is less than *20* per cent a gratuity not exceeding £500 may be granted in lieu of retired pay

Literature —White paper, Cd 8631, price *2d* , from H M Stationery Office

MILITARY SERVICE (CIVIL LIABILITIES) COMMITTEE

Object —To grant pecuniary assistance to men, married or unmarried, serving with H M Forces who are unable by reason of undertaking military service to meet their financial obligations

Benefits —Applicants must *not* hold a *commission*, and must be ordinarily resident in the United Kingdom Assistance is granted in respect of rent, interest and repayment of loans, instalments under agreements of purchase rates and taxes, insurance premiums, school fees, but is not available for ordinary debts

Amount —Not to exceed £104 per annum (= £2 a week) paid quarterly

Conditions —The assistance may not be assigned and is liable to revision or withdrawal at any time It ceases on discharge from the Forces In case the grantee is reported dead or missing the assistance may be continued for 26 weeks to his widow or dependents

Application —Commissioners have been appointed for 45 districts in England 3 in Wales, and 18 in Scotland A list of addresses can be inspected at any post-office Application should be made to the Commissioner for the district in which the applicant or his family resides, on a form obtainable at the post-office

Literature —A white paper, Cd 8249, price 1½*d* , from H.M Stationery Office, gives all necessary information

PROFESSIONAL CLASSES WAR RELIEF COUNCIL (INC)

Object —To assist the families of professional men whose circumstances have been adversely affected by the war Those serving with H M Forces (without holding commissions) are advised to confer first with the Civil Liabilities Committee

Benefits —When granted these have been of a substantial character Up to the issue of the last report assistance had been granted to the extent of £10,851 for the education of 631 children, 256 babies had been born in the maternity home, and 103 candidates helped with their training at a cost of £1300

Application —The central office of the Council is at 13–14, Princes gate, S W 7 (*Tel Kensington* 6394/5) Chairman Major Leonard Darwin Chairman of executive Dr S West Honorary secretaries Theo G Chambers, Alex. Goddard Secretary Miss Percy Taylor Interviews by appointment only There are eight members of the medical profession on the Council—*namely*, Sir Thomas Barlow, Lady Barrett, Sir Francis Champneys, Sir Watson Cheyne, Dr G Newton Pitt, Mrs Scharlieb, Sir Frederick Taylor, Dr S West

Literature —The annual report for 1916 on application to the secretary

OFFICERS' FAMILIES FUND

Object —To assist *the wives and other* dependent relatives of officers in the Navy and Army (including service battalions, the Territorial Forces, Indian Army, and Colonial Forces) who find themselves in financial embarrassment or other trouble owing to direct or indirect expenses resulting from the war

Benefits —Assistance is provided in the form of (1) money, (2) medical assistance, with the coöperation of doctors, nurses, and maternity homes (Florence Nightingale Hospital, Lisson Grove) , (3) education, already given to 475 girls and boys (honorary secretary, Mr E H Parry), (4) clothing depôt for men at 2, Albert Gate, S W 5 , for women and children at 29, Berkeley square, W 1, managed by Lady Wilson), *(5) business advice* (chairman, Lord Justice Warrington, 2000 personal interviews have been given) (6) employment During the two years 1914–16 in all 9506 grants have been made, amounting to nearly £200,000, while 476 widows and 172 mothers have been assisted

Application —The central office of the Fund is at Lansdowne House, Berkeley square W 1 Honorary secretary, Countess Roberts Secretary, Miss H M Kelly *Interviews 11-1* (except Thursday and Saturday), or by appointment

Literature —A two-page leaflet on application Report of two years' work up to August, 1916

AUXILIARY R A M C FUNDS

Object —*(a)* Officers' Benevolent Branch To assist the orphans of commissioned officers of the three auxiliary branches of the R A M C —viz , the Special Reserve, the Territorial Force, and the New Armies—serving during the present war *(b)* Relief Branch *To assist the widows* and orphans of the rank and file of the same branches A similar fund has existed since 1820 in the regular R.A M.C

Benefits (of the Benevolent Branch) —Relief is given in respect of each orphan up to a maximum of *£40* in a year, and to the age of *21* years (boys) or *18* years (girls) A female orphan has a claim if over 50 years and unmarried, or at any age if unfit *Loss of both* parents constitutes a superior claim for relief, and priority is given to the relatives of officers killed in action, or who died of wounds or disease caused by active service Donations are given, not annuities.

Application —The office of the benevolent branch is at *124, Victoria street, S W 1 (Tel Vict 2722) President* Sir A Keogh Chairman Major Ewen Maclean Secretary, Lieutenant-Colonel E M Wilson Application should be made on or before July 1st in any year, the distribution taking place annually in October

Literature —A four page leaflet and a *14* page *book of rules* on application

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN

Object —To provide for the necessitous widows and orphans of its members

Conditions of membership —Membership is open to any registered medical practitioner *resident at the time* of his election within a 20 mile radius of Charing Cross The annual subscription is £2 2*s* Relief is granted in respect of life members and those of three years' standing

Benefits —A widow with an assured income of less than £100 a year receives £50 annually, *plus* £43 a year *for each orphan* up to 16 years of age The Copeland and Brickwell funds permit of further grants in special cases In the year 1916 £4223 odd was distributed, and on *the last day* of the year 48 widows and 9 orphans were in receipt of grants

Application —Secretary, 11, *Chandos street, Cavendish* square, W 1

Literature —The report *for 1916*, a *four* page leaflet, on application , also a statement of receipts, and expenditure for 1916

WAR EMERGENCY FUND OF THE ROYAL MEDICAL BENEVOLENT FUND

Object —A special department *of* the Royal Medical Benevolent Fund to afford assistance to members of the medical profession who find themselves in temporary difficulties, consequent on having joined the Army *Medical* Service

Benefits —Grants on a liberal scale *will be made* in respect of rent, insurance, taxes, family maintenance and education, *in so far as the needs are not met* by any other existing fund if the necessary funds are forthcoming

Application —The office of the Fund is at 11, Chandos street, Cavendish square, W 1 (Tel *Mayfair* 1043) President, Dr S West Honorary treasurer, Colonel Charters Symonds Honorary secretary, Major G Newton Pitt The application will be investigated by one member of the committee of the Fund individually and laid before the Executive Committee anonymously

Literature —An appeal form on application

MEDICAL PATRIOTIC FUND OF THE B M A

At the last Annual Representative Meeting of the British Medical Association a scheme for loan fund for the protection and assistance of those who went to the war and on coming home found themselves in temporary difficulties was brought in by a subcommittee appointed for the purpose A resolution as follows was passed —

> This meeting approves the principle *of the* Medical Patriotic Fund (Loan Fund) Scheme and instructs the Council to consider and if approved to launch the scheme on the cessation of hostilities or earlier if the need arise unless in the meantime *amalgamation or coöperation* of existing funds shall render the establishment of an independent fund unnecessary or undesirable

THE BIOLOGICAL ASPECTS OF WARFARE

BY HARRY CAMPBELL, M.D LOND, F R C.P LOND,
PHYSICIAN TO THE WEST-END HOSPITAL FOR NERVOUS DISEASES LONDON

II *

The Two Sanctions of Conduct

A MAN'S conduct both towards his fellow man and the lower animals has two justifications or sanctions—the self-regarding sanction of might and the "others" regarding sanction of altruism.

Let us first consider the sanction of might—the justification, that is, for exercising might wholly or essentially in the interest of self It is expressed in the phrase "Might is right." According to this sanction what might can do that might is justified in doing The first great truth we have to realise respecting the might sanction is that sheer might, wholly untempered by consideration for others, operates with inexorable effect throughout the whole organic world In the struggle for existence living things have to contend against one another and against the forces of Nature, and in this struggle those go under that cannot successfully oppose might by might As regards the struggle between living things, the most lowly may be pitted against and overcome the most exalted, as when man succumbs to a microbic disease such as phthisis In a life-and-death struggle of this kind there is no sanction other than might, the victim has meekly to submit to the inevitable. Nor has he from the biological standpoint great cause for complaint seeing that from that standpoint the lowly tubercle bacillus has just as much right to live as man, the roof and crown of things

Let us now ask ourselves how far the sanction of sheer might prevails among the higher vertebrates—(*a*) between the sub-human vertebrates (*b*) between man and the latter, and (*c*) between man and man.

A.—The struggle among the lower animals is signally displayed in the case of the carnivora and their prey Here we see the operation of might in its grimmest and most dramatic aspect The sole warrant for the butchering activities of these animals is manifestly that of might although it must be admitted that a measure of altruistic sanction comes into play in the case of the carnivorous mother when she slaughters for the sake of her offspring

B —We have seen that since the time the pre human ape took to hunting he and his human descendants have wrought ruthless havoc among the lower animals Here again the sanction is just that of the other carnivora—the sanction of might—the self same sanction which permits the tiger to kill the deer or the cat the mouse Biologically considered, the victims of man and the carnivora generally have just the same right to a place in the sun as their victimisers Man may perhaps console himself somewhat for his indulgence in this wholesale slaughter by the reflection that if a race of superior beings were to descend upon this planet they would assuredly very speedily enslave or destroy the human race, and still more from the consideration, already urged, that it has been essentially through bloodshed that man has raised himself above the ape

C —The might sanction obtains widely as between man and man both as regards the relations between separate communities be they savage tribes or great nations, and those between the individual members constituting these communities The sanction for that subjugation of weaker tribes by stronger which has taken place throughout the entire period of man's tribal career has manifestly been that of might simply And so too as regards the warfare between civilised nations Even in this year of grace the dread arbitrament of war still continues to be the sole means for settling disputes which cannot otherwise be adjusted. The great nations of the world still refuse to lay aside their arms and submit their disputes to an international tribunal. Men like Treitschke and Bernhardi boldly proclaim that in international disputes might is right, and openly advocate the cultivation of the martial spirit and a prompt resort to arms if by their means the power and influence of the Fatherland seem likely to be extended The only gleam of better things comes in the fact that the great powers of the Entente are fighting not only in their own cause but in that of the small, i.e the weak, nationalities

Again, among the individual members of a community, tribal or national, we find the strong dominating the weak. This is true even of advanced civilised communities Actual personal combat is still in some degree sanctioned in the case of the comparatively harmless schoolboy fight and in the more formidable duel Happily, the latter method of settling personal differences has long since been given up in this country It is a flagrant instance of the might sanction in its most primitive form one man injures another, the injured person challenges the injurer, but far from being certain of getting reparation, he as likely as not receives additional injury if, indeed he is fortunate enough to escape with his life Here the sanction is just the same and just as little justifiable on rational or ethical grounds, as when two great nations engage in war

The individual is not, of course permitted unreservedly to exercise the might sanction in his own interests within the State Without some restrictions (to be considered later) no community could hold together Nevertheless, these restraints, considerable though they be, leave wide scope for the exercise of personal might in the interest of self, and there are few who fail to take advantage of it The tendency is for everyone to use such powers as he is free to exercise, without actually breaking the law or acting in violent defiance of public opinion for the purpose of securing for himself the good things of this world

The exercise of might within the sanction of the law falls under two categories though it is not easy to draw a sharp line between them We may speak of them as the illegitimate and the legitimate.

The illegitimate though legalised exercise of might includes conduct which, though essentially immoral is yet permissible by law the fact being that in a complex social system no code of laws can be devised which shall take account of every possible form of immoral dealing Hence it is possible for a person without breaking the law, to use his might in a manner which has little or no moral justification Large fortunes are made in ways which, though not illegal, are yet violently opposed to the spirit of altruism, as in the case of the man who establishes a corner in wheat, the employer who sweats his workers, the usurer who lends money at exorbitant interest Many of these procedures are santioned by general consent, though they are little more than modes of legalised robbery Has not the informed and skilful speculator something in common with the house-breaker ? Each uses his skill in annexing the property of others by taking advantage of their ignorance, while he renders no manner of service to the State Is it not, again, a matter of daily experience that when a person no matter what his social position has the legal power to squeeze another in his own interest he seldom fails to take advantage of it ?

We come now to the second category—the legitimate exercise of might in furtherance of self interest Some people are endued with greater powers than others, and society sanctions the exercise by the individual, in furtherance of self interest of such powers as he possesses provided he does not infringe the law or act in flagrant defiance of public opinion Herbert Spencer's formula of Justice runs thus Every man is free to do that which he wills provided he infringes not the equal freedom of any other man '

Now it will be found on ultimate analysis that the sanction here is not that of ideal justice—at least not of ideal justice as I conceive it—but just that of might Ideal justice demands, so it seems to me, that all shall start life equally endowed (both as regards native powers and worldly goods) and further that all shall be afforded equal opportunity But neither of these conditions obtains or can obtain. Nothing is more certain than that all are not equally endowed Dame Fortune distributes her favours in an entirely haphazard fashion. Some are gifted with a larger native endowment than others in the matter of health beauty intelligence force of character, or what not, and are able to reap corresponding advantages Some, again, are born rich others poor and what cannot the power of wealth accomplish ? The moneyed fool can command the service of multitudes and enjoy in abundance the good things of this world, while the penniless genius may starve in a garret. Then as regards differences of opportunity Some are born under conditions affording little scope for native endowment to come by her own. Village Hampdens and mute inglorious Miltons are more common than we think A man who attains to modest eminence in a small provincial town might, had he sought his fortune in the New World, have made his millions, or a village beauty who, like the heroine of that beautiful poem ' Maud Muller," has had to content herself with an uncouth swain for consort, might, had she been afforded the opportunity to display her charms behind the footlights, have blossomed into a peeress Power without opportunity is powerless

---

* Article I was published in THE LANCET of Sept. 15th, p 433

Under ideally just conditions, which require that each and all shall be equally endowed as to person and opportunity, no one could secure an advantage over his fellows from the possession of an extra share of might It may be argued that even under such conditions it would still be possible for some by superior industry and grit to outstrip others in the race for life's prizes and thus secure a legitimate reward for having of *their own free will* made the best of their talents To which I would reply that this very industry and this very grit are part and parcel of the individual endowment Here we are up against the old question of the freedom of the will To me it seems that equality of endowment implies equality as regards industry and force of character, and that feelings thoughts, and acts conform to undeviating laws

We thus see that ideal justice is not possible, but we are not on that account to suppose that everyone ought to forgo the special benefits which blind fortune may have bestowed upon him, or that an attempt should be made to secure ideal justice by a quixotic altruism It is idle to strive after the impracticable or to seek to over ride the great biological law of struggle - throughout all living nature the battle is, and ever will be, to the strong A vigorous individualism, subject to necessary legal restrictions and tempered by a generous altruism, is the ideal to be aimed at Subject to these reservations, might is a legitimate sanction My object has merely been to show that this sanction operates with potent effect, even in the most advanced and best-regulated communities

(*Note* —The conclusion here arrived at as to the legitimacy of exercising might within the limits specified has the authority of Herbert Spencer He points out that, except in the case of the immature throughout the entire animal kingdom the benefits received tend to be in direct proportion to the merits possessed, an arrangement which necessarily secures the survival of the fittest "Each individual" he insists, "ought to be subject to the effects of its own nature and resulting conduct," a principle which among the lower animals holds good without qualification Among men there is an instinctive craving for freedom of action, and Spencer maintains that this freedom should be permitted so long as it does not interfere unduly with the freedom of others)

The Checks to the Operation of Might

We have seen how the might sanction operates throughout the entire animal kingdom and how even in advanced human societies its potency is far greater than appears at first sight Let us now consider more particularly some of the restraints which limit its operation Among the most effective of these is the altruistic prompting which leads parents to tend their offspring This parental instinct is now recognised to be the foundation of all altruism—the generous impulse to work in the interest of others rather than of self

All animals which tend their young must at least be endowed with just so much altruism as pertains to the parental instinct, whether maternal, paternal, or both (In the case of mammals the care of the young is for the most part limited to the mother) It is, moreover necessary that the entire family group shall be pervaded by something akin to the altruistic spirit, or at least that the members of the group shall not act antagonistically to one another in order that they may cohere and live in harmony together In the case of the non gregarious animals this parental and family altruism constitutes the sole check on the might sanction Save for its influence the non gregarious animal (the tiger, for instance) employs all its powers for selfish ends alone.

In the case of gregarious animals other checks come into play, but before dealing with these it will be well to examine into the purpose of gregariousness Its object is mutual help By union into an organised community the welfare of each animal in that community may be promoted Thus the capture of prey may be facilitated, as in the case of the wolf which, by hunting in packs can secure a more ample supply of food than by individual effort, or again, the union may serve the purpose of protection, as in the case of many of the herbivora (e g, the deer and the ox), for the herd not only presents a united front to the enemy, but by the multiplicity of its organs of scent and vision is so much the more appreciative of approaching danger Man's gregariousness has a similar *raison d etre* That primitive human families combined into tribes for utilitarian purposes we are very sure. Their union enabled the men to coöperate in the hunt and the women in the gathering and preparation of vegetable food, while it served the further purpose of protection against enemies, human or other The interest of this utilitarian communal life as bearing on our present inquiry lies in the influence it has had in creating checks on the régime of pure might—checks which, becoming increasingly stringent with the development of communal life, have attained to greatest stringency in the most advanced civilised communities

And first as to the checks on the operation of might among infra human communities My remarks on this head must be brief It is obvious that no community could hold together if each member worked for its own interest without any reference to its fellows Some psychic influence, antithetic to the purely egoistic manifestation of might and tending to secure the cohesion of the whole, must be at work And such is undoubtedly the case Thus some glimmer of altruism may be observed among the members of the herd in the shape of mutual help, and, again, a harmful assertion of might on the part of one member of the herd may lead to its being chastised by other members or even outlawed from the community, as in the case of the malicious rogue elephant In short, each member of the herd needs to discipline its conduct in due regard to the others in order that all may live together harmoniously and coöperate for common ends

And as with infra human so with human communities—the individual members need to be bound together by psychic influences, which constitute so many restraints on the purely egoistic might sanction. When families began to unite into tribes the altruism, until then confined to the family group, extended to the entire tribe, for some measure of mutual help, however small, was necessary to its cohesion This also required that certain rules of conduct should be observed, rules which, indeed, in many cases developed a complexity out of all proportion to their usefulness (as in the case of those in force among the Australian aborigines) These rules were not deliberately framed, but grew up spontaneously and were perpetuated and emphasised by tradition. Nor were they enforced by an executive but simply by public opinion, fear of which ever constitutes an effective check on unconventional conduct Disputes between members of the tribe—private wrongs such as theft and even murder—were settled privately The injured persons took the law into their own hands (as we say) and avenged themselves as best they could by retaliation the fear of which like the fear of public opinion, always operates as a useful restraint

It was not, indeed, until a comparatively late phase of social evolution that Government undertook the protection of the individual In the first instance, its sole concern—its *raison d etre*, in fact—was the military one of protecting the community against external foes, tribal customs enforced by public opinion and the fear of retaliation against private wrongs, aided by some measure of altruistic spirit, sufficing to maintain the integrity of the tribe But something more than these was necessary to protect the tribe against outside enemies This demanded a central authority in the person of a chief or king whose business it should be to weld the manhood of the tribe into a fighting force Needless to say, that at this primitive phase of society there was no question of exemption owing to conscientious motives The first duty of all the able-bodied men—and these comprised practically the entire manhood of the tribe—was to preserve the integrity of the tribe against attack We have thus an ancient precedent for universal military service Assuredly the first duty of a government is now, as it was at the first beginning of communal life to secure adequate defence of the state against its enemies and to compel, if need be all its able bodied manhood not otherwise required to take up arms against the common foe. The man who is deaf to this elemental call of duty is an undesirable from the eugenic standpoint. From such as him we are little likely to breed a virile race; we must not, we cannot allow our bravest and best to be killed while the faint hearted are left to perpetuate the race.

As society developed government undertook the duty of protecting the interests of the individual by enacting and enforcing laws, and thus a further check was put upon the operation of might. Meanwhile another and most powerful restraining influence had come into operation—the fear of divine vengeance. But to trace the growth of the religious element in man would take me beyond the scope of this essay and I merely name it.

The operation of these various checks during countless generations has had a profound influence on man's affective nature. There has evolved in consequence of them a disposition to act in accordance with the requirements of complex social life, for on the whole those most amenable to social discipline and those most altruistically disposed have survived at the expense of the anti social and the egoistic; there has evolved, in short, a disposition to act morally (i.e. dutifully towards our fellows), and a corresponding sense of justice has been built up. Thus it has come about that from the first institution of communal life among men there has been a steady weakening of the might sanction, so that to-day civilised man revolts against its unbridled exercise. He realises that while it is excellent to have a giant's strength it is tyrannous to use it like a giant, and he applauds the "noble doom" which Posthumus imposes upon the man who has wronged him:—

> Kneel not to me:
> The power I have on you is to spare you;
> The malice towards you, to forgive you: live,
> And deal with others better.

It will thus be seen that just as communal life has evolved on a utilitarian basis so also has morality; its function is neither more nor less than the maintenance of the integrity of the social organism. From the biological standpoint it has no other significance. Nor must it be forgotten that sheer might has also its range of usefulness in the animal world, a wider even perhaps than that of *altruism*. Each is but a means to an end and biologically neither merits commendation or condemnation more than the other.

(FROM OUR OWN CORRESPONDENT.)

Ear Protection against Concussion.

NUMEROUS symptoms in combatants due to the effect on the ears of the explosion of large projectiles have led to the consideration of equally numerous means for the protection of the hearing apparatus. Gunners are advised to keep their mouths open at the moment of firing. For the unexpected bursting of projectiles various methods of protection have been recommended, but it has been found necessary to discard all—among them cotton wool pads—which appreciably diminish the perception of sound and so prevent the soldier from hearing the word of command. In practice hollow perforated obturators are the best. These are placed in the external auditory canal so as to allow of the passage of sound waves through the double perforation, while the cavity arrests the force of the larger waves, so that they reach the drum membrane much attenuated. MM. L. and M. Vérain have laid two models of these obturators before the *Academy of Medicine*. They are made of celluloid or aluminium in the shape of an olive and are perforated at each extremity. In one model each hole leads by a T shaped tube into the interior. The simpler method is divided into two compartments by a transverse diaphragm pierced by a simple hole from which a small hollow rod penetrates into the anterior compartment. More than 600 pairs of these obturators were employed in two months in an artillery regiment, and during this time not a single case of tinnitus, vertigo, hæmorrhage, or obstruction by wax was observed. M. Jacques, of the 8th Army, is responsible for a still simpler model consisting of a spherical capsule of gelatin, such as are used to contain medicaments, after emptying the contents through a small hole pierced at each end. The size of the hole is regulated by the sensitiveness in the particular case. The results obtained with this model have been as satisfactory as with the others.

Professional Secrecy and the Exposure of Criminal Abortion.

Feeling runs strong in French medical circles in regard to the proposal under discussion at the Academy of Medicine dealing with the causes of depopulation and the strenuous repression of abortion, and numerous articles are appearing in the medical and lay press. The proposal is to release the medical man from his obligation of professional secrecy when he is called to appear for the prosecution in case of a criminal abortion of which he has professional knowledge. M. Berthélémy, professor in the Parisian Faculty of Law, recently declared before the Société de Médecine Légale that the abortion danger had become so great as to render advisable abolition *of the obligation to professional secrecy and of the impunity* to the guilty which this obligation conferred. The society adopted this view, with the rider that the doctor should not be liable to prosecution if he believed he had answered conscientiously the questions put to him by the legal authority, and that it was his duty to take the initiative in denouncing the authors of abortion when he learned of them through the confession of his patient, since such persons were outside the protection accorded by the obligation of secrecy. Dr. Lepage, a hospital accoucheur, believes that the reform will have no practical value, because the doctor can rarely be certain of the measures taken to produce abortion unless he possesses a formal confession from the patient, which the latter will hesitate to give, not being herself protected by the seal of secrecy. M. Doléris regards the duty of exposing the authors of abortion as an absolute one, constituting the only means of restraining their nefarious activities. The president of the Society of Medical Practitioners declares, on the other hand, that professional secrecy should be observed in all circumstances, for otherwise patients will no longer venture to confide in their doctors, and thus remaining unattended will die in greater numbers than before without any reduction in the number of abortion-mongers. The controversy continues.

Sept. 10th.

THE CONTROL OF VENEREAL DISEASES.

Prohibition of Unqualified Treatment.

ACTING on the powers conferred upon it by the Venereal Disease Act, 1917, the Local Government Board has prohibited from Nov. 1st next the treatment of venereal disease except by duly qualified persons, in the counties of Buckingham, Cambridge, Durham, Essex, Hereford, Hertford, Isle of Ely, Kent, Leicester, London, Middlesex, Norfolk, Northampton, Northumberland, and Surrey, and in the county boroughs of Bootle, Bradford, Cardiff, Coventry, Croydon, Darlington, Dewsbury, Dudley, East Ham, Hastings, Leeds, Leicester, Newcastle upon-Tyne, Northampton, Norwich, Portsmouth, Sunderland, Tynemouth, Wakefield, Warrington, and West Ham. Persons contravening the provisions of the section are liable to imprisonment for two years or to a fine of £100.

The City of London Treatment Centre.

The treatment centre which was recently opened by Lieutenant-Colonel W. R. Smith, R.A.M.C., chairman of the Sanitary Committee of the City Corporation, is situated at the City Shelter, 19-20 Golden lane, E.C. The times of attendance are: For men, Wednesdays 12–2 and Fridays 5–7; for women and children, Mondays 12–2. Captain W. Girling Ball is the officer in charge. The initial outlay on the centre has been about £1400, and the annual working expenses are estimated at £1800, plus £400 for salvarsan.

National Council for Combating Venereal Diseases.

Following on successful public meetings local branches of the National Council have recently been formed at Manchester and at Canterbury.

Venereal Disease and Marriage.

At a recent session of the New York State Legislature an amendment to the Domestic Relations Law was placed on the statute books requiring all persons applying for a marriage licence to take the following oath:—

> I have not to my knowledge been infected with any venereal disease, or if I have been so infected within five years I have had a laboratory test within that period which shows that I am now free from infection from any such disease.

The mere taking of such an oath will naturally not make attains to modest eminence in a small provincial town might, had he sought his fortune in the New World, have made his millions , or a village beauty who, like the heroine of that beautiful poem ' Maud Muller," has had to content herself with an uncouth swain for consort, might, had she been afforded the opportunity to display her charms behind the footlights have blossomed into a peeress Power without opportunity is powerless

Under ideally just conditions, which require that each and all shall be equally endowed as to person and opportunity, no one could secure an advantage over his fellows from the possession of an extra share of might It may be argued that even under such conditions it would still be possible for some by superior industry and grit to outstrip others in the race for life's prizes and thus secure a legitimate reward for having of *their own free will* made the best of their talents To which I would reply that this very industry and this very grit are part and parcel of the individual endowment Here we are up against the old question of the freedom of the will To me it seems that equality of endowment implies equality as regards industry and force of character, and that feelings thoughts, and acts conform to undeviating laws

We thus see that ideal justice is not possible, but we are not on that account to suppose that everyone ought to forgo the special benefits which blind fortune may have bestowed upon him, or that an attempt should be made to secure ideal justice by a quixotic altruism It is idle to strive after the impracticable or to seek to over-ride the great biological law of struggle throughout all living nature the battle is, and ever will be, to the strong A vigorous individualism, subject to necessary legal restrictions and tempered by a generous altruism, is the ideal to be aimed at Subject to these reservations, might is a legitimate sanction My object has merely been to show that this sanction operates with potent effect, even in the most advanced and best regulated communities

(*Note* —The conclusion here arrived at as to the legitimacy of exercising might within the limits specified has the authority of Herbert Spencer He points out that except in the case of the immature throughout the entire animal kingdom the benefits received tend to be in direct proportion to the merits possessed, an arrangement which necessarily secures the survival of the fittest "Each individual " he insists, "ought to be subject to the effects of its own nature and resulting conduct, ' a principle which among the lower animals holds good without qualification Among men there is an instinctive craving for freedom of action, and Spencer maintains that this freedom should be permitted so long as it does not interfere unduly with the freedom of others)

The Checks to the Operation of Might

We have seen how the might sanction operates throughout the entire animal kingdom, and how even in advanced human societies its potency is far greater than appears at first sight Let us now consider more particularly some of the restraints which limit its operation Among the most effective of these is the altruistic prompting which leads parents to tend their offspring This parental instinct is now recognised to be the foundation of all altruism—the generous impulse to work in the interest of others rather than of self

Ear Protection against Concussion

NUMEROUS symptoms in combatants due to the effect on the ears of the explosion of large projectiles have led to the consideration of equally numerous means for the protection of the hearing apparatus Gunners are advised to keep their mouths open at the moment of firing For the unexpected bursting of projectiles various methods of protection have been recommended, but it has been found necessary to discard all—among them cotton wool pads—which appreciably diminish the perception of sound and so prevent the soldier from hearing the word of command In practice hollow perforated obturators are the best These are placed in the external auditory canal so as to allow of the passage of sound waves through the double perforation, while the cavity arrests the force of the larger waves, so that they reach the drum membrane much attenuated MM L and M Vérain have laid two models of these obturators before the Academy of Medicine They are made of celluloid or aluminium in the shape of an olive and are perforated at each extremity In one model each hole leads by a T shaped tube into the interior The simpler method is divided into two compartments by a transverse diaphragm pierced by a simple hole from which a small hollow rod penetrates into the anterior compartment. More than 600 pairs of these obturators were employed in two months in an artillery regiment, and during this time not a single case of tinnitus vertigo hæmorrhage or obstruction by wax was observed M Jacques, of the 8th Army is responsible for a still simpler model consisting of a spherical capsule of gelatin such as are used to contain medicaments after emptying the contents through a small hole pierced at each end The size of the hole is regulated by the sensitiveness in the particular case. The results obtained with this model have been as satisfactory as with the others.

Professional Secrecy and the Exposure of Criminal Abortion

Feeling runs strong in French medical circles in regard to the proposal under discussion at the Academy of Medicine dealing with the causes of depopulation and the strenuous repression of abortion and numerous articles are appearing in the medical and lay press The proposal is to release the medical man from his obligation of professional secrecy when he is called to appear for the prosecution in case of a criminal abortion of which he has professional knowledge M Berthélemy professor in the Parisian Faculty of Law, recently declared before the Société de Médecine Légale that the abortion danger had become so great as to render advisable abolition of the obligation to professional secrecy and of the impunity to the guilty which this obligation conferred The society adopted this view, with the rider that the doctor should not be liable to prosecution if he believed he had answered conscientiously the questions put to him by the legal authority , and that it was his duty to take the initiative in denouncing the authors of abortion when he learned of them through the confession of his patient since such persons were outside the protection accorded by the obligation of secrecy Dr Lepage, a hospital accoucheur, believes that the reform will have no practical value, because the doctor can rarely be certain of the measures taken to produce abortion unless he possesses a formal confession from the patient, which the latter will hesitate to give not being herself protected by the seal of secrecy M Doléris regards the duty of exposing the authors of abortion as an absolute one, constituting the only means of restraining their nefarious activities The president of the Society of Medical Practitioners declares, on the other hand, that professional secrecy should be observed in all circumstances, for otherwise patients will no longer venture to confide in their doctors, and thus remaining unattended will die in greater numbers than before without any reduction in the number of abortion-mongers The controversy continues

Sept 10th

THE CONTROL OF VENEREAL DISEASES

Prohibition of Unqualified Treatment

ACTING on the powers conferred upon it by the Venereal Disease Act, 1917 the Local Government Board has prohibited, from Nov 1st next, the treatment of venereal disease, except by duly qualified persons, in the counties of Buckingham, Cambridge, Durham, Essex, Hereford, Hertford Isle of Ely, Kent, Leicester, London, Middlesex, Norfolk, Northampton Northumberland, and Surrey, and in the county boroughs of Bootle, Bradford, Cardiff, Coventry, Croydon Darlington Dewsbury, Dudley, East Ham, Hastings, Leeds, Leicester, Newcastle upon Tyne, Northampton, Norwich Portsmouth, Sunderland, Tynemouth, Wakefield, Warrington, and West Ham Persons contravening the provisions of the section are liable to imprisonment for two years or to a fine of £100

The City of London Treatment Centre

The treatment centre which was recently opened by Lieutenant-Colonel W R Smith, R A.M C , chairman of the Sanitary Committee of the City Corporation is situated at the City Shelter 19 20 Golden lane, E C The times of attendance are For men Wednesdays 12–2 and Fridays 5–7 , for women and children Mondays 12–2 Captain W Girling Ball is the officer in charge The initial outlay on the centre has been about £1400 and the annual working expenses are estimated at £1800, plus £400 for salvarsan

National Council for Combating Venereal Diseases

Following on successful public meetings local branches of the National Council have recently been formed at Manchester and at Canterbury

Venereal Disease and Marriage

At a recent session of the New York State Legislature an amendment to the Domestic Relations Law was placed on the statute books requiring all persons applying for a marriage licence to take the following oath —

> I have not to my knowledge been infected with any venereal disease or if I have been so infected within five years I have had a laboratory test within that period which shows that I am now free from infection from any such disease

The mere taking of such an oath will naturally not make absolutely certain that both parties are free from infection at the time of marriage, but the new law will nevertheless exert an important educational influence on public opinion

Compulsory Detention in South Africa

Dr Chales Porter, medical officer of health of Johannesburg, has reported to the municipal council that under the Local Government Ordinance, 1912, Section 72 (3), the council has power to make by laws for preventing the outbreak and spread not only of infectious diseases, but also of contagious diseases, and for the segregation and treatment of sufferers from contagious diseases, the word 'contagious" having been inserted at the suggestion of the medical officer of health Several specific instances have come to the notice of the medical officer of health in which a sufferer from venereal disease in a contagious condition has refused to go to the isolation hospital or to remain there, with resulting danger to those with whom he comes in contact The medical officer of the prison has represented that at present he is compelled to discharge uncured from his hospital at the expiration of their sentences both white and coloured persons suffering from various forms of venereal disease, often in a highly contagious state In view of these facts the health committee has recommended to the council to make the following new by-law —

> When any person is suffering from any contagious disease and when in the opinion of the medical officer of health the removal of such person to a suitable hospital or place of segregation and his detention or treatment therein are necessary for the protection of the public health the council may order and compel the removal and treatment of such person in such hospital or place of segregation and his detention therein until in the opinion of the medical superintendent of such hospital or place of segregation he has ceased to be in a contagious condition In the event of any such contagious person resisting such removal or detention any official of the council or any police constable or other person authorised thereto by the council and any official of the place of detention may employ such force as may be necessary to compel such removal and detention Any such person who resists such removal or resists or wilfully evades such detention shall be liable to a penalty not exceeding fifty pounds (£50) or in default of payment, to imprisonment for a period not exceeding three months

The Interpretation of the Wassermann Reaction

The London County Council has issued, for the use of its venereal treatment centres, a memorandum originally drafted by the pathologist of one of the London hospitals, and embodying certain additions suggested by other pathologists of treatment centres The enormous number of tests, which have been made during the ten years since the reaction was introduced, have left no doubt the memorandum states, as to the meaning to be attached to definitely positive or negative results in the great majority of cases, but in regard to certain points it cannot be said that universal agreement has been reached The conclusions suggested in these special cases represent only the general trend of opinion The Wassermann reaction is a quantitative one—i e , it depends on a certain phenomenon occurring to a certain degree and hence there will always be border line reactions, which, while showing a distinct departure from the normal, are not sufficiently marked to serve as a basis for a definite diagnosis save under special circumstances Such reactions, when they occur, must be carefully considered in relation to all the known facts of the case in question After discussing in succession the reaction in diagnosis, the effect of treatment on the reaction, the reaction in the control of treatment and the reaction as a criterion of infectivity, the following conclusions are given —

1 A well marked positive reaction is undoubted evidence of syphilitic infection with the few unimportant reservations outlined above

2 A single negative result has no value during the first few weeks of the disease At this stage the *sore* should be examined for the *Spirochæta pallida* and if the result be negative the blood should be tested after a short interval, during which no treatment has been given

3 A negative result in a patient undergoing treatment has no diagnostic value If the diagnosis be uncertain the test must be repeated after a treatment-free interval lasting for several weeks at least

4 A negative result in an untreated case exhibiting suspected secondary lesions almost excludes syphilis but never does so absolutely

5 In the later stages with certain exceptions, a rather higher proportion of undoubted syphilitic cases give negative results so that such a result while contraindicating a diagnosis of this disease especially if previous anti syphilitic treatment can be excluded must be regarded in relation to all other available evidence

6 In using the reaction to control treatment the ideal aimed at should be a persistently negative reaction following a prolonged and thorough course of treatment, as explained above This result, combined with the absence of all clinical signs, is the best evidence of on infectivity

7 A weak positive reaction must always be considered in relation to ll the known facts of the case and has little diagnostic value alone

The memorandum closes with drawing the attention of medical practitioners who wish to take advantage of the laboratory facilities provided by the local authorities to the following suggestions —

1 The facilities are intended for cases of venereal diseases in their *early and in all communicable stages*

2. The examination for spirochætes is most efficient when the patient attends for the purpose at the treatment centre

3 It is understood that the pathologists may refuse to perform any tests in the following circumstances : (*a*) when the material arrives in an unsatisfactory condition (*b*) when the form of particulars is not completely filled up by the practitioner

Enlightenment Campaign amongst American Recruits

Dr C F Bolduan director of the Bureau of Public Health Education for the City of New York, writes to us of the advantage taken of the opportunities of sexual enlightenment offered by the recruiting for the United States Army In New York City there were 188 exemption boards who medically examined more than 150,000 recruits. In cooperation with the New York Social Hygiene Society the City Department of Health prepared a pamphlet for distribution to the drafted men being examined and asked the examining officers to hand a copy to each man examined by them. The pamphlet, which is entitled "Universal Service and Physical Fitness," is of eight pages, and gives a graphic account of the devastating effects of venereal infection. One [illegible] of the [illegible] devoted to a telling [illegible] page is [illegible] between pictorial illustration of the triple alliance [illegible] alcohol, prostitution, and quackery, another [illegible] the theories of the necessity and justification of illicit intercourse. On the cover stands the motto Public health is purchasable Within natural limitations a community can determine its own death rate

Experiences of an American Venereal Dispensary

In the *American Journal of Public Health* for May Dr Alec N Thomson, of New York City, gives an account of the dispensary problems of gonorrhœa and syphilis as encountered in the work of the genito-urinary department of the Brooklyn Hospital Dispensary Established in 1904, by Dr Rathbun as sole worker, it now occupies 15 doctors at six afternoon seven evening, and two morning clinic sessions The aim of the clinic is to bring the patient under treatment and retain him until cured, and no pains are spared to ensure this When visits are omitted a reminder is sent in a sealed envelope, repeated again where unnoticed, and finally with the stamp, "Your last chance" Above the door of the waiting room to the clinic are two large signs reading "You must come to the clinic regularly for treatment," and 'Do not stop treatment until the doctor tells you that you are well" Each new case admitted to the dispensary also receives a ten page pamphlet upon venereal diseases Metal plates offering the facilities of the Department of Health for advice and diagnosis and of the Brooklyn Hospital Dispensary for the treatment of diseases of men have been placed in a number of saloon and factory toilets, replacing in many cases the quack signs Dr Thomson is convinced that it pays to advertise Publicity and education will, he says, deprive the quack of his biggest assets—mystery and ignorance Affiliation with such other bodies as the American Social Hygiene Association is essential to this end

AWKWARD PRESCRIPTIONS

BY A W BROMLEY,
PHARMACIST

To a pharmacist an awkward prescription is one containing a chemical incompatible, an ambiguity an error, or an unusually large dose In the last case, the dose may be intentional on the part of the prescriber for some special or heroic reason, or merely a verbal or arithmetical slip The obvious course in all such difficulties is to appeal to the prescriber if he is accessible. But there are many cases where that is not possible or desirable. One cannot delay a prescription obviously urgent to consult the writer in a distant town I once posted a doubtful prescription to its author in the West-End It followed him to Scotland, and I received it back in four days That is an extreme case but I have had delays of several hours, where prescribers live quite close to me, and a delay till the next morning

Many doctors would perhaps define an incompatible either as a "messy mixture" or as a chemical decomposition Neither definition is good An incompatible mixture may be quite elegant and, of course, many decompositions are not incompatibilities I would rather define a chemical incompatibility as a decomposition in which the chemical or physical properties of the result are different from the intention disclosed Of course, an incompatibility may not be chemical. An acid added to an emulsion would generally produce a physical incompatibility Most incompatibles that arise in practice are crude and obvious, but a few are interesting If a trifling omission addition or substitution will set them right, all but the fussiest pharmacists would do that without troubling the prescriber But of course the change must be of no medicinal importance Sometimes, without medical knowledge, it is possible to anticipate the normal prescriber s mental process in a prescription difficulty and deduce his inevitable decision For example I omitted glycerine from a potassium permanganate gargle Obviously they could not be put together, nor could a substitute be introduced, the prescriber s way out of the difficulty was inevitable. To assume that he would discard his carefully selected main ingredient for the sake of a demulcent would be to convict him of weak judgment in prescribing An equally clear case was a mixture of quinine and iron citrate, and sal volatile The latter might be wanted for its alkalinity, its stimulating effect or s a flavour The first two purposes are defeated by the cidity of the citrate, it can only act as a flavour So an ppropriate quantity of lemon and nutmeg essences was ubstituted. A mixture of sodium salicylate, sodium bicarbonate and tincture of iron was cured by substituting iron and ammonium citrate for the tincture In this case the prescriber was told and he approved, in the others the matter was decided as too trivial to communicate

A dangerous but extremely common incompatible is a mixture of solution of strychnine with alkalies Yet it is by no means undispensable Strychnine is slightly soluble in water and it becomes a question of where the danger point is Theoretically the most that is safe is about half a grain (50 minims of solution) in 8 oz But a drachm in 6 oz is dispensed every day, with a ' shake" label of course Trouble could only arise through a very remote coincidence The patient would have to pour out very carefully without shaking all but the last few doses and then reform and shake thoroughly Such procedure would yield doses ranging from 0 6 to 1 5 or more of the dose prescribed Pharmacists do not like these mixtures that rely upon the patient s intelligent obedience. I should dispense a tablespoon mixture double size with ounce doses if the strength exceeded 10 minims per ounce.

A very interesting incompatible is the decomposition of chloral hydrate by alkalies It can scarcely be regarded as dangerous or even seriously objectionable, probably the decomposition is not always completed in mixtures occurring in practice. If it is completed the patient gets the sudden action of chloroform instead of the gradual action of chloral As a rule, pharmacists would dispense as written without comment, if the prescriber himself brought the prescription one might raise the point

Ambiguities arise through bad writing close similarities in the names of drugs and synonyms that have more than one meaning It is curious how one can master the details of a prescription by inference from its general construction when not a single word can be read Only when a bad writer happens to be also an eccentric prescriber does he create insurmountable difficulties for the dispenser

Sometimes possibly only in moments of irritation a prescriber expects one to carry the process of deduction too far I once took a defective prescription to its author, and after correcting it he asked what I should have done had he been inaccessible On my mentioning two alternatives he remarked Either would have suited me and been better for the patient than this delay ' In another case I received an urgent order for 3-minim amyl nitrite capsules Not having them I sent the messenger hurrying to my nearest colleague Next day the doctor told me that considering the obvious emergency I should have supplied 5-minim capsules rather than send the messenger away One can see the point of view here without agreeing A pharmacist cannot solve doubts by guess only by reasoning which must at least be sound to himself.

Correspondence.

"Audi alteram partem."

THE "HÆMOGREGARINE" OF TRENCH FEVER

To the Editor of THE LANCET

SIR,—In THE LANCET of Sept 8th, in a paper entitled 'Trench Fever or P U O, associated with the Presence of a Hæmogregarine," Captain Lyn Dimond R A.M C, announces the discovery of hæmogregarines in human blood If this statement should prove to be correct, then a discovery of the first magnitude has been made, as such parasites, though occurring in reptiles amphibia, &c. and in some mammals (dog, rat jerboa) have not so far been found in man. In view of the importance of Captain Dimond's find, therefore, it behoves tropical workers and protozoologists critically to examine his results to see if they are well founded and accurate. A study of the somewhat rough pen and ink sketches which accompany the paper is certainly not convincing, and the feeling of doubt which these give rise to is increased when the life cycle described for the hæmogregarine is taken into account This as compared with the cycle which has been worked out for the hæmogregarine of the lizard and rat, is inaccurate in many respects, and is largely based on hypothesis with no definite facts to support it Further, even granting for a moment that the bodies seen are hæmogregarines, there is no evidence that they are pathogenic or the cause of trench fever This is borne out by a statement made by the author towards the end of his paper that since completing it he has had opportunities of confirming the presence of the hæmogregarines in a number of other cases of trench fever and also in addition in cases of D A H, complicated with some of the clinical signs of P U O and in one or two cases of definite benign tertian malaria It is strange if hæmogregarines are present in the latter disease that they have never been seen before by workers in tropical medicine I have said enough to show that urgent confirmation of the discovery is required and until this is forthcoming the matter must remain *sub judice* Recommendations have been made to puncture the lungs and other viscera in order to obtain venous blood a somewhat dangerous procedure for all and sundry to adopt. and flavine and other drugs have been used for treatment. There is no justification for this until it is definitely shown (1) that the bodies described are hæmogregarines and (2) that they are pathogenic and the cause of the disease. Sir David Bruce, President of the Society of Tropical Medicine and Hygiene and the Fellows generally will, I am sure, be only too pleased to give Captain Dimond the opportunity of demonstrating his parasites before them and expert opinion will then be available to test their validity

I am Sir, yours faithfully,

GEORGE C LOW M D,

Temp Captain, I M S Lecturer London School of Tropical Medicine Joint Secretary Society of Tropical Medicine and Hygiene

Bentinck-street W Sept 15th, 1917

To the Editor of THE LANCET

SIR.—In your issue of Sept 8th you publish an article by Captain Lyn Dimond, entitled ' Trench Fever or P U O, associated with the Presence of a Hæmogregarine ' From a leading article in the same issue, and from personal communications and interrogations which I have received since the appearance of this work I gather that there is in some quarters a tendency to regard Captain Dimond's findings favourably and to conclude that he has discovered in man a new protozoal parasite—a hæmogregarine—which is the cause of trench fever I therefore ask your permission to make a few comments from the point of view of a protozoologist upon this remarkable publication

In the first place I would point out that Captain Dimond s statements are frequently very difficult for a protozoologist to understand, since he displays a singular disregard for the language of our science, and I may perhaps have failed to seize his meaning in consequence. When for example, he

BREAST-FEEDING AND THE NERVOUS INFANT

To the Editor of THE LANCET

SIR —I am probably not alone in having felt puzzled by the explanation recently offered by Dr H C Cameron in your columns,[1] of a certain form of restless behaviour in infants For it is a startling suggestion that a baby is not uncommonly so baffled by being called upon to take up extra uterine existence that it loses its head and makes a complete hash of the whole business of feeding This is neuropathic inheritance with a vengeance!

There can be no question that in this article, as in all his writings on the subject of childhood, Dr Cameron has drawn an essentially accurate clinical picture But in attributing its cause to the child's endowment with an unstable nervous disposition he has, I believe, disregarded certain factors which need consideration There are, at any rate, other things capable of producing something resembling very closely the state of affairs to which he is calling attention

For example, in any investigation into the causes of restlessness crying, and reluctance to feed, which may be marked for several days after birth, it is necessary to take into account the variable effect on the child's brain of the stress of labour Signs of pressure on the head are commonly seen in the form of œdema of the scalp, moulding of the skull, and subperiosteal extravasation of blood Not very rarely death may precede or quickly follow delivery from intracranial venous laceration, without any sign of outward violence From a consideration of these facts it would seem reasonable to suppose we must expect considerable difference in the initial behaviour of infants corresponding to the ease or difficulty of their journey through the pelvis I have certainly regarded the symptoms of several babies which corresponded closely to Dr Cameron's description as explained in this way, and have used sedatives with apparent benefit In one such case a midwife told me she believed that the infant "had a bad headache" so clearly did it display a dislike to light or movement Her diagnosis was probably accurate enough, and for such a child it would clearly be wise to adopt the line of treatment suggested "A half-darkened room," "absolute quiet" and 'gentle handling" form wise advice though I believe attempts at feeding may largely be left in abeyance until the condition passes off. Chloral will be beneficial in lessening cerebral irritability But one would suppose that had it to overcome anything so formidable as a precocious display of neurotic instability, its administration would have to be prolonged very considerably

Whether the explanation here offered for some cases is right or not it cannot of course, apply to instances where the child s behaviour is normal at the start and unrest supervenes later But, again, there are causes of some importance which need to be eliminated before it is wise to conclude that the infant is "neurotic' or its cry "hysterical' Dr Cameron's statement that the mother's rôle in establishing successful breast-feeding is confined to the possession of an adequately shaped nipple, is not very helpful It omits altogether the important provision that the milk which leaves the nipple must be of a kind which will not disturb the baby Normally of course it is perfectly innocuous But there can be no question that it may in certain circumstances be so unsuitable as to produce pain, vomiting, a refusal to feed, and all the symptoms of unrest which he discusses

The common fear of nursing women to include this or that article of food in their diet is not entirely without a basis of reason But any disturbance resulting from indiscretions of food is trivial when compared with the effects of drastic purgation to which many are accustomed to resort and which is still perhaps the most rigid feature of obstetrical ritual The woman is lucky who escapes such purgation during labour, she catches it almost invariably throughout the puerperium Paradoxically enough the intestinal fatigue, the flatulence headache and general misery thus produced are labelled ' constipation" and as a daily action of some kind is insisted upon enemata of large volume are commonly added Nowhere are enema rashes to be seen with such frequency as in maternity hospitals and the teaching on this point is dogmatic stern and impressive When the toxæmia which must accompany such a state be considered, it is not surprising that the infant is disturbed The midwife or physician in attendance on nursing women has only to be sufficiently enthusiastic about the need to keep the bowels open, and one can guarantee with a very fair degree of safety the baby before long will "almost jump out of her arms" One can understand its fear of the breast milk, even its cautious distrust of the bottle until the contents have been proved harmless One cannot grudge it any relief to be gleaned from a few doses of chloral hydrate But to attribute the dyspepsia as due primarily to an inherited nervous instability would be distinctly unjust to the baby It would, moreover render the chance of successful breast-feeding remote, and leave the cause of its failure undetected

In THE LANCET of Nov 4th 1916, I described another common pathological condition of the mother which is certainly productive of unrest in the infant Disease in connexion with the teeth whether or not responsible for obvious maternal ill health, frequently reacts on the child in a manner perhaps comparable to the effect produced by purgatives In outlining certain features of the behaviour of babies thus affected, I referred to their tendency to be of poor physique, to their refusal to feed, and to the vomiting 'of an intractable type, variable from day to day, sometimes interrupting the feed, sometimes following soon after its conclusion, at others interfering with sleep and accompanied by attacks of screaming which may last for hours The vomiting has a tendency to be frequent, copious, and forcible and the woman rightly concludes that her milk disagrees with the baby" Though somewhat more emphasis is there laid on the vomiting, the account tallies sufficiently with Dr Cameron's to make me wonder whether dental disease or some other source of toxæmia in the mother may account for some of "thin, meagre' children he describes

In bringing forward these causes of disturbance which lead commonly to a failure of breast nursing, I do not wish to imply that all children are endowed at birth with an equally placid temperament but rather to emphasise the need for care lest one include in the class of case Dr Cameron has described conditions which have a quite different etiology, and which demand in consequence investigation along quite different lines —I am, Sir, yours faithfully

Gray's Inn W C Sept 9th 1917 HAROLD WALLER

PSYCHIATRY IN ENGLAND

To the Editor of THE LANCET

SIR,—In answer to Dr H de M Alexander, I admit the methods of the English Commissioners in Lunacy *re* recovery rate may have their faults, but for comparison's sake it suffices to know that they themselves are far from being content with (what I still call) 'the lamentable fact" that recovery rate in asylums has not increased in spite of all that has so far been done' I believe I am right in saying that the Scottish Board of Commissioners admit the same fact without giving any definite cause for this reproach to psychiatry and to the laws which have in England hindered the early treatment in proper environment of mental disease

As to the ages of patients admitted I maintain that if cases are taken in hand promptly and the patients are studied clinically in all aspects, the best arrangements being made for treatment and environment we get many recoveries in quite elderly people

I am delighted that Dr Alexander feels himself justified in stating 'There must be few if any asylums in which the want of proper departmentisation of cases occurs" I wish he would in confidence give me the names of English asylums public and private, in which he knows that this practice is carried out to the extent I consider is necessary Dr Alexander s quotation from a work of my valued friend the late Sir Thomas Clouston is a very true one, but may I remind Dr Alexander that that splendid clinical student of mental diseases has made many statements in his numerous books in accordance with my expressed views and experience ?

The law of lunacy as carried out in England differs to a great extent from that of Scotland, which allows much more scope for early treatment either in proper homes or in asylums So far we have tried in vain to get our lunacy laws altered in this direction and it has been very disheartening work to sit on committees with this object and with no result, as I well know to my cost.

I am, Sir, yours faithfully

Bournemouth Sept. 16th 1917 L A WEATHERLY M D describes his "hæmogregarine 'as undergoing multiplication by the "sporulation" of a "parthenogenetic gametocyte" into "merozoites," he produces a *feeling of bewilderment* in his readers, for this, translated from the *patois* of protozoology, as applied to Sporozoa, into common English, means that the bisexually produced germs, or spores of the parasite are asexually produced young produced unisexually It is difficult to know what meaning to attribute to such propositions but reference to the illustrations permits one to make a plausible guess Are not Figs I–IV, the "parthenogenetic gametocytes," in reality sketched from dried and stained cellular elements of the human spleen or liver? And are not the "20 parthenogenetically produced merozoites" of Fig V in reality 19 bacteria? Their resemblance to these things is undeniable, whilst their lack of resemblance to any known stages in the life history of a hæmogregarine is equally undeniable We now know the life histories of a few species of hæmogregarines almost completely of several others in considerable detail, and of the numerous remainder in consistent fragments But nothing like the remarkable development outlined by Captain Dimond for his ' hæmogregarine" has previously been brought to light Indeed there is *not only* no hæmogregarine which develops like his, but there is no known *protozoon* whatever like it To the best of my knowledge it is unique in many ways among all known organisms

---

[1] THE LANCET 1917, ii 345

Figs. VI and VII are more difficult of interpretation It is not possible to discover what they really represent They bear, indeed some resemblance to hæmogregarines, but also display some notable differences The intracorpuscular "parasites" of Fig VIII are also difficult of interpretation They appear to inhabit red blood corpuscles of extraordinarily small size (one is two and a half, the other slightly over three microns in diameter) and to be themselves far smaller than any ordinary hæmogregarines On comparing the descriptions with the figures, and taking the rest of the ' *life history" of the "protozoon" into account no proto*zoologist would, I believe, care to express a very definite opinion on these *forms until* he had *studied* the actual specimens from which they were drawn There are so many pitfalls in the path of the unwary hunter of blood parasites, and the cautionary stories of "*Paraplasma*" and '*Anaplasma*" are still so fresh in our memories, that one is chary of expressing an opinion prematurely in such matters

After reading Captain Dimond's article, therefore I immediately wrote to ask him to allow me to examine his preparations I thought his published statements might become intelligible when taken in conjunction with the actual objects of his descriptions He must, I inferred possess a very large number of preparations containing all the stages which he describes or mentions and a vast number of intermediates, since he describes with much confidence a life cycle of *great complexity* and *novelty* In answer to my request I have received a letter (from Major W Byam) in which it is *stated* that a *further report* is in preparation and when that is complete he "hopes *to prepare* and forward smears" for my examination "For the *present*," he says, "we feel that both microscopical and clinical demonstrations would take more time than we can afford" This being the case, therefore, there is little further discussion possible at present It is only just to remark, however that the account of the "hæmogregarine of trench fever" can only be accepted when a complete series of preparations is produced in evidence, or when its existence and its almost incredible life cycle are independently confirmed by a protozoologist of unquestionable competence and repute

It is unfortunate that Captain Dimond did not take the precaution of consulting a protozoologist with first-hand knowledge of the hæmogregarines, and also of consulting the somewhat extensive literature dealing with this group of protozoa *before recording* his findings Had he done so he could hardly have published his work in the form in which it now appears He would also probably have saved himself much trouble and labour For example, it appears that he is now seeking the further developmental stages of his "hæmogregarine" *in* lice which he regards as being with "extreme probability," the intermediate hosts He says further, that ' the presence of *such* large numbers of rats in the trenches which come into close association with our troops seems to favour this *conclusion*" Assuming that he means that the rats, and not the trenches, associate with our troops, it is extremely difficult to follow his train of thought *It is true* that a louse—*Hæmatopinus stephensi*—to which he refers is believed to be the intermediate host *of the* hæmogregarine of the Indian gerbil But our common rat harbours a hæmogregarine whose *life history* happens to have been worked out in considerable detail It is nothing like that described by Captain Dimond and its intermediate host is not a louse It is not even an insect So far as our knowledge extends it is the exception rather than the rule for a hæmogregarine to have an insect for its invertebrate host

There is much other matter in Captain Dimond's paper which lays itself open to, and even invites, the most destructive criticism I will not, however, further trespass upon your space My sole object in writing this letter is to call attention to the extremely debatable character of the "hæmogregarine of trench fever" I cannot but regard it as a duty to the unfortunate sufferers from this affliction to express my misgivings, as a protozoologist, to those members of the medical profession who have a practical interest in the subject but who are unversed in *our science* It is with considerable apprehension that I contemplate the possibility *of future investigators exploring the lungs, livers*, spleens, and other organs of sick soldiers in the hunt for a "hæmogregarine" whose very existence I can only regard as highly hypothetic *I do not deny* that Captain Dimond *may* have discovered the parasite which causes trench fever At present I cannot discover what he has discovered in the way of parasites But I will venture to predict, Sir that when you stated in your leading article that "the broad facts of the life-cycle of the parasite appear to be established" you expressed an opinion to which no competent protozoologist will subscribe

I am, Sir, yours faithfully,

CLIFFORD DOBELL

Imperial College of Science Sept. 17th 1917

THE LUMLEIAN LECTURES AND MEDICAL RESEARCH

To the Editor of THE LANCET

SIR,—Some of us have watched with breathless interest the great struggle of the cardiologists in your columns conducted under the heading, "The Lumleian Lectures and Medical Research" The origin of *the struggle* was humorous Dr F Smith, in a pungent but rather true letter, pointed out that if we labour the obvious enough we shall make a new discovery of its obviousness, and I was guilty in the next week of pointing out that the *English study* of heart disease was, if judged by the lectures, already out of date Then the "new" school, as led by their *formidable* and renowned chief, created a dramatic surprise by disclosing a grievous lack of knowledge of the literature *of the* most important cause of heart disease, and finally the two schools approached one another much as did the famous Mac's of music hall fame—with sweet words, gradually changing towards fierce blows

It is *now*, I think, a suitable time for the medical profession to join the new school I have been advocating As I write this I have before me a special number of *American Medicine* for June, 1915 in which by invitation I wrote an article on the *prevention* of rheumatism and heart disease I have also the second annual report of the 'Winifred Masterson Burke Relief *Foundation*" New York, in which institution the suggestions I put forward are being put into practice with most encouraging results Let me state explicitly that I do not pretend that my article was responsible for this forward *step* but taken with the recent work on rheumatism I, with others, may justly claim to have lent such an enterprise reasonable scientific support

Two years after this article the enterprise is in full activity in America Nearly *20 years* after acute rheumatism was shown in this country to be an infection no such effort has been attempted We are still worrying about mitral stenosis and digitalis and think that hospitals can alone deal with the problems of heart disease

Let us now think of the service that institution has already done to practical medicine and *mourn* over the wordy controversies upon academic details that have marred our English medical literature —I am Sir, yours *faithfully*,

F JOHN POYNTON

Sept. 12th 1917

BREAST-FEEDING AND THE NERVOUS INFANT

To the Editor of THE LANCET

SIR,—I am probably not alone in having felt puzzled by the explanation, recently offered by Dr H O Cameron in your columns,[1] of a certain form of restless behaviour in infants For it is a startling suggestion that a baby is not uncommonly so baffled by being called upon to take up extra uterine existence that it loses its head and makes a complete hash of the whole business of feeding This is neuropathic inheritance with a vengeance!

There can be no question that in this article, as in all his writings on the subject of childhood, Dr Cameron has drawn an essentially accurate clinical picture But in attributing its cause to the child's endowment with an unstable nervous disposition he has, I believe, disregarded certain factors which need consideration There are, at any rate, other things capable of producing something resembling very closely the state of affairs to which he is calling attention

For example, in any investigation into the causes of restlessness crying, and reluctance to feed, which may be marked for several days after birth, it is necessary to take into account the variable effect on the child's brain of the stress of labour Signs of pressure on the head are commonly seen in the form of œdema of the scalp moulding of the skull and subperiosteal extravasation of blood Not very rarely death may precede or quickly follow delivery from intracranial venous laceration, without any sign of outward violence From a consideration of these facts it would seem reasonable to suppose we must expect considerable difference in the initial behaviour of infants corresponding to the ease or difficulty of their journey through the pelvis I have certainly regarded the symptoms of several babies which corresponded closely to Dr Cameron's description as explained in this way, and have used sedatives with apparent benefit In one such case a midwife told me she believed that the infant "had a bad headache," so clearly did it display a dislike to light or movement. Her diagnosis was probably accurate enough, and for such a child it would clearly be wise to adopt the line of treatment suggested "A half-darkened room" "absolute quiet" and 'gentle handling" form wise advice, though I believe attempts at feeding may largely be left in abeyance until the condition passes off Chloral will be beneficial in lessening cerebral irritability But one would suppose that had it to overcome anything so formidable as a precocious display of neurotic instability its administration would have to be prolonged very considerably

Whether the explanation here offered for some cases is right or not it cannot, of course, apply to instances where the child's behaviour is normal at the start and unrest supervenes later But, again, there are causes of some importance which need to be eliminated before it is wise to conclude that the infant is "neurotic" or its cry 'hysterical" Dr Cameron's statement that the mother's rôle in establishing successful breast-feeding is confined to the possession of an adequately shaped nipple, is not very helpful It omits altogether the important provision that the milk which leaves the nipple must be of a kind which will not disturb the baby Normally of course it is perfectly innocuous But there can be no question that it may in certain circumstances be so unsuitable as to produce pain, vomiting, a refusal to feed, and all the symptoms of unrest which he discusses

The common fear of nursing women to include this or that article of food in their diet is not entirely without a basis of reason But any disturbance resulting from indiscretions of food is trivial when compared with the effects of drastic purgation to which many are accustomed to resort and which is still perhaps the most rigid feature of obstetrical ritual The woman is lucky who escapes such purgation during labour, she catches it almost invariably throughout the puerperium Paradoxically enough the intestinal fatigue, the flatulence headache and general misery thus produced are labelled "constipation' and as a daily action of some kind is insisted upon enemata of large volume are commonly added Nowhere are enema rashes to be seen with such frequency as in maternity hospitals and the teaching on this point is dogmatic stern, and impressive When the toxæmia which must accompany such a state be considered, it is not surprising that the infant is disturbed The midwife or physician in attendance on nursing women has only to be sufficiently enthusiastic about the need to keep the bowels open, and one can guarantee with a very fair degree of safety the baby before long will "almost jump out of her arms" One can understand its fear of the breast milk, even its cautious distrust of the bottle until the contents have been proved harmless One cannot grudge it any relief to be gleaned from a few doses of chloral hydrate But to attribute the dyspepsia as due primarily to an inherited nervous instability would be distinctly unjust to the baby It would, moreover render the chance of successful breast-feeding remote, and leave the cause of its failure undetected

In THE LANCET of Nov 4th, 1916, I described another common pathological condition of the mother which is certainly productive of unrest in the infant Disease in connexion with the teeth whether or not responsible for obvious maternal ill health, frequently reacts on the child in a manner perhaps comparable to the effect produced by purgatives In outlining certain features of the behaviour of babies thus affected, I referred to their tendency to be of poor physique, to their refusal to feed and to the vomiting 'of an intractable type, variable from day to day, sometimes interrupting the feed, sometimes following soon after its conclusion, at others interfering with sleep and accompanied by attacks of screaming which may last for hours The vomiting has a tendency to be frequent copious, and forcible, and the woman rightly concludes that her milk disagrees with the baby" Though somewhat more emphasis is there laid on the vomiting, the account tallies sufficiently with Dr Cameron's to make me wonder whether dental disease or some other source of toxæmia in the mother may account for some of "thin meagre" children he describes

In bringing forward these causes of disturbance which lead commonly to a failure of breast nursing, I do not wish to imply that all children are endowed at birth with an equally placid temperament, but rather to emphasise the need for care lest one include in the class of case Dr Cameron has described conditions which have a quite different etiology and which demand in consequence investigation along quite different lines —I am, Sir yours faithfully

Gray's Inn W C Sept. 9th 1917 HAROLD WALLER

PSYCHIATRY IN ENGLAND

To the Editor of THE LANCET

SIR,—In answer to Dr H de M Alexander, I admit the methods of the English Commissioners in Lunacy *re* recovery rate may have their faults but for comparison's sake it suffices to know that they themselves are far from being content with (what I still call) "the lamentable fact" that recovery rate in asylums has not increased in spite of all that has so far been done' I believe I am right in saying that the Scottish Board of Commissioners admit the same fact without giving any definite cause for this reproach to psychiatry and to the laws which have in England hindered the early treatment in proper environment of mental disease

As to the ages of patients admitted I maintain that if cases are taken in hand promptly and the patients are studied clinically in all aspects, the best arrangements being made for treatment and environment, we get many recoveries in quite elderly people

I am delighted that Dr Alexander feels himself justified in stating 'There must be few, if any asylums in which the want of proper departmentisation of cases occurs" I wish he would in confidence give me the names of English asylums, public and private in which he knows that this practice is carried out to the extent I consider is necessary Dr Alexander's quotation from a work of my valued friend the late Sir Thomas Clouston is a very true one, but may I remind Dr Alexander that that splendid clinical student of mental diseases has made many statements in his numerous books in accordance with my expressed views and experience?

The law of lunacy as carried out in England differs to a great extent from that of Scotland, which allows much more scope for early treatment, either in proper homes or in asylums So far we have tried in vain to get our lunacy laws altered in this direction, and it has been very disheartening work to sit on committees with this object and with no result, as I well know to my cost

I am, Sir, yours faithfully

BRITISH HEALTH RESORTS

To the Editor of THE LANCET

SIR,—I was asked some time ago to prepare for Messrs A and C Black a guide to British health resorts, endeavouring, as far as possible, to bring into prominence the many attractions which our own country offers in the way of first-class spas and seaside resorts Apart from the well known spas, however, there are many wells and springs scattered through the country which have at least a local repute and are of some historic interest

I shall be very grateful to any members of the profession or others who will kindly send me details of any such wells, &c , in their district, so that the chapter it is proposed to include on this subject may be as complete and informative as possible All our big spas had small beginnings, and who knows some of these at present neglected sources of mineralised water may be of value and blossom out into health resorts ? It is, at any rate, believed and hoped that once the war is over most people will think twice before taking a journey to Germany and leaving money, which could with equal benefit and greater propriety be spent at home, in the blood stained hands of the Teuton

No one who was caught napping at Nauheim Homburg, Kissingen, or Wiesbaden, at the end of July 1914, will willingly enter Germany again in search of health That is pretty certain —I am, Sir, yours faithfully,

T D LUKE, M D R U I

DEATHS IN THE SERVICES

Surg Gen William *Simson Pratt*, C B R.A.M C (retired) at Bideford on Sept 8th aged 68. Formerly he was Principal Medical Officer in the Southern Command and in 1900 he was appointed Principal *Medical* Officer at Gibraltar For his services in the Nile Expedition in 1884-85 he was mentioned in despatches and promoted Surgeon *Major* He reached the rank of Lieutenant Colonel in 1893 and of Colonel in 1902

Obituary.

FREDERIC WILLIAM KIDD, M D DUB , L R C P & S

PROFESSOR OF MIDWIFERY AT THE ROYAL COLLEGE OF *SURGEONS* I IRELAND EX MASTER OF AND CONSULTING SURGEON TO *THE* COOMBE LYING-IN HOSPITAL AND GYNÆCOLOGIST TO THE MEATH HOSPITAL.

WE announced last week the sudden death of Dr Freder William Kidd, which took place at his residence in Dubli on Sept 5th He received his medical education at Trinit College and in the Carmichael School, Dublin Obtainin an arts degree in 1880, he qualified in the following year b taking the L R C S Irel , graduating M D at the University of Dublin six years later Subsequently he took th Licentiateship of the Royal College of Physicians of Ireland In 1884 he was elected a Fellow of the Royal Academy of Medicine in Ireland, served on the council as an honorary member, and was President of the *Obstetrical* Section. His many other appointments included those of examiner in gynæcology at the Royal College of Surgeons in Ireland and examiner in midwifery at the University of Dublin He was also a Past-President of the Irish Medical Association and an ex member of the council of the British Gynæcological Society

Dr Kidd held a position of great respect among his colleagues, and in both clinical and academic circles his loss will be much felt, for the post of visiting gynæcologist to the Meath Hospital and County Dublin Infirmary and the chair of midwifery in the schools of surgery have been vacated by his death, after many years of able and untiring service He was a frequent contributor to the Transactions of the Royal Academy of Medicine in Ireland in the departments of his profession in which he was interested

Many years ago Dr Kidd was a well known *Rugby* footballer and as a member of Lansdowne Club he gained his International cap and played *v* Scotland at Belfast in 1877 and *v* England at Dublin in 1878 He leaves four sons, all of whom are serving with His Majesty's Forces His kindly personality and the unfailing interest he took in the welfare of his students gained for him a wide circle of friends, to whom the news of his death has come with a sense of personal loss

THE LATE DR JOHN ROBERTS THOMSON, V D—Dr Thomson, who died at his residence Monkchester Bournemouth, at the age of 73, on Sept 11th was educated at Edinburgh University, and qualified in 1865 by taking the Licentiateship of the Royal College of Surgeons of Edinburgh A year later he graduated M D of Edinburgh University, and subsequently, in 1880, became a Fellow of the Royal College of Physicians of London He was consulting physician to the Royal Victoria and West Hants Hospital Bournemouth, the Firs Home for Consumption, and the Royal National Sanatorium for Consumption and Diseases of the Chest He was a Vice President of the British Medical Association, having been President in 1891, when the Association held its annual meeting at Bournemouth, and President of Council Dr Thomson was a justice of the peace for Hants and the borough of Bournemouth and an alderman of the Hants county council

---

Dr Christoph Socin, assistant at the *Basle* Institute of Pathology, has been appointed professor of pathological anatomy and director of the Pathological Institute at Lausanne

The War.

THE CASUALTY LIST

THE following names of medical officers appear among the casualties announced since our last issue —

Killed

Lieut A G Dunn, R A M C, received his medical education at Newcastle-on Tyne, and qualified in 1903 Prior to joining up he was in practice at Newcastle-on Tyne, and held an appointment at the Royal Victoria Infirmary in that city

Died of Wounds

Capt B Woodhouse R A M C, received his medical education at University College Hospital, London, and qualified in 1913 He joined the R A.M C shortly afterwards, and was promoted Captain in March, 1915

Wounded

Capt A. L Anthony, R A.M C, attached Royal Warwick Regiment
Capt N J H Gavin, M C, R A M C
Capt J S Taylor, R A M C, attached Rifle Brigade
Capt R W Hodgson-Jones, R A M C
Lieut W G McConnell, R A M C, attached Yorks and Lancs Regiment
Lieut-Col J Barkley, R A.M C
Capt W C D Maile, R A M C
Capt A H Falkner, R A.M C, attached Royal Lancs Regiment
Capt L J Moir, R A M C
Capt G W Stanley, R A M C
Capt P A Doyle, R.A M C
Lieut. M J Macauley R A.M C
Capt L R Shore, M C, R.A M C
Capt L M Weeks, R A M C
Capt W L R Wood, M C, R A M C, attached Royal Field Artillery
Lieut H Snape R A M C
Capt T H Whittington R A M C, attached Essex Regt
Lieut Col H Gibson, R A M C
Capt. J Lyons, R A.M C
Capt H Moore M C R A M C
Capt J F W Sandison, R A.M C

CASUALTIES AMONG THE SONS OF MEDICAL MEN

The following additional casualty among the sons of medical men is reported —

Major H S Semple, M C Royal Engineers, killed in action, eldest son of Dr H F Semple, of Budleigh Salterton, Devon

THE HONOURS LIST

Clasp to the Victoria Cross

The highest award for bravery and devotion to duty in the face of the enemy has again been bestowed upon a member of the medical profession Captain N G Chavasse who has, most regretfully be it recorded, paid the supreme sacrifice The official announcement is as follows —

Capt Noel Godfrey Chavasse V C, M C, late R A.M C, attached Liverpool Regiment

For most conspicuous bravery and devotion to duty when in action. Though severely wounded early in the action whilst carrying a wounded soldier to the dressing station Captain Chavasse refused to leave his post and for two days not only continued to perform his duties but in addition went out repeatedly under heavy fire to search for and attend to the wounded who were lying out. During these searches although practically without food during this period, worn with fatigue and faint with his wound he assisted to carry in a number of badly wounded men over heavy and difficult ground By his extraordinary energy and inspiring example he was instrumental in rescuing many wounded who would have otherwise undoubtedly succumbed under the bad weather conditions. This devoted and gallant officer subsequently died of his wounds

Captain Chavasse was the younger of the twin sons of the Lord Bishop of Liverpool and was educated at Liverpool College and at Oxford qualifying in 1912. His death from wounds was recorded in THE LANCET of August 18th (p 259) whilst the awards of the M C and of the V C were recorded in our issues respectively of Jan 22nd 1916 (p 215) and of Nov 4th 1916 (p 806)

The following promotions of and awards to medical officers are also announced —

To be Brevet Lieutenant Colonel

Major (temp Lieut Col) R M Carter, I M S

Distinguished Service Order

Temp Capt Lewis Anderson, R.A M C

For conspicuous gallantry and devotion to duty He carried out his duties for 48 hours without relief attending to over 100 cases and working under the most adverse conditions He was exposed throughout to intense and heavy fire of shell and gas shells, which rendered it necessary for him to work in a mask The following night after his battalion had been withdrawn he returned to search for wounded in the front line which was still in close contact with the enemy and after working for several hours under heavy shell fire he collected and evacuated all his wounded having displayed magnificent devotion and the utmost contempt for danger throughout

Capt (Temp Lieut Col) Norman Cecil Rutherford, R A.M C

For conspicuous gallantry and devotion to duty when in charge of an advanced dressing station He worked continuously under heavy shell fire evacuating the wounded from the forward area, and it was owing to his splendid example of devotion that the work was efficiently carried out

Major Robert Archer Lloyd, I M S

Lieut (temp Capt) Arthur Frederick Isbell Patterson, R A M C

Military Cross

Capt John Ernest Affleck, Canadian A M C

For conspicuous gallantry and devotion to duty He crawled along a shallow and much-exposed trench to rescue a very severely wounded officer whose life depended upon an immediate operation With the assistance of a stretcher bearer he managed to get the wounded man out on a blanket to a place where he could be evacuated The task was a very slow and dangerous one by reason of their being completely exposed to enemy snipers but Capt Affleck did not hesitate to risk his life in order to do all that was humanly possible for this wounded officer

Capt John Arthur Bell, R A.M C

For conspicuous gallantry and devotion to duty during a heavy bombardment He proceeded along a road which was exposed to the most intense shell fire in order to attend to four wounded officers He dressed their wounds and remained with them until they were evacuated by motor ambulance which was only accomplished with the greatest difficulty owing to the heavy shelling His absolute disregard of danger and devotion to duty amidst terrific shell fire were exceptionally splendid and beyond all praise

Capt John Bernard Cavenagh, R A M C, Spec Res

For conspicuous gallantry and devotion to duty when in charge of bearers He exposed himself to shell fire for 48 hours with splendid fearlessness keeping all the time in touch with aid posts in the captured line thereby ensuring a rapid evacuation of the wounded

Capt Clarence Hamul Denyer, R A M C

For conspicuous gallantry and devotion to duty when in command of divisional bearers It was due to his fearless and capable handling of his party that the evacuation of the wounded was carried out with rapidity and success

Temp Capt Charles Dickson, R A M C

For conspicuous gallantry and devotion to duty when in charge of an advanced dressing station Under an intense high explosive and gas shell bombardment the building was *partially* wrecked and the patients were in danger of death from gas poisoning He at once personally organised a working party to replace the anti gas screens and take other precautions for the safety of the wounded this necessitated working in the open under extremely heavy fire, during which his total disregard of safety set a most inspiring example to his men By his energy and devotion the lives of many badly wounded men were saved

Temp Capt Charles Dundee, R A.M C

For conspicuous gallantry and devotion to duty He worked for three days, bandaging the wounded under fire and successfully evacuating every case in his battalion almost as soon as they occurred Over 500 cases passed through his hands and he displayed a splendid spirit of energy and devotion

Temp Lieut David Hammond Fraser, R A.M C

For conspicuous gallantry and devotion to duty Whilst his battery was under very heavy gas bombardment a shell wrecked the officers mess dug-out and buried two officers and five men Lieut Fraser helped by a corporal most gallantly assisted to rescue the buried men and restore respiration entering the dug-out several times until he eventually collapsed from the gas On recovering consciousness he again attempted to enter the dug out, but was prevented from doing so Later he collapsed again and remained unconscious for a long time It was due to his promptness and energy that no more than two of the gassed men succumbed

Temp Capt Augustus Joseph Hickey, R A M C

For conspicuous gallantry and devotion to duty when in command of an advanced dressing station He worked with the utmost energy and disregard of danger for 48 hours under shell fire, during which time he passed through more than 700 wounded His skill and devotion saved many lives

Temp Capt William Bird Loveless, R A.M C

For conspicuous gallantry and devotion to duty in tending the wounded under heavy shell fire Although wounded in the face early in the day he did not leave his post but continued with his work until he came out of action with his battalion displaying splendid keenness and devotion to duty

BRITISH HEALTH RESORTS

Dr Kidd held a position of great respect among his colleagues, and in both clinical and academic circles his loss will be much felt, for the post of visiting gynæcologist to the Meath Hospital and County Dublin Infirmary and the chair of midwifery in the schools of surgery have been vacated by his death, after many years of able and untiring service He was a frequent contributor to the Transactions of the Royal Academy of Medicine in Ireland in the departments of his profession in which he was interested

Many years ago Dr Kidd was a well known Rugby footballer and as a member of Lansdowne Club he gained his International cap and played *v* Scotland at Belfast in 1877 and *v* England at Dublin in 1878 He leaves four sons all of whom are serving with His Majesty's Forces His kindly personality and the unfailing interest he took in the welfare of his students gained for him a wide circle of friends, to whom the news of his death has come with a sense of personal loss

THE LATE DR JOHN ROBERTS THOMSON, V D—Dr Thomson, who died at his residence Monkchester, Bournemouth, at the age of 73, on Sept 11th, was educated at Edinburgh University and qualified in 1865 by taking the Licentiateship of the Royal College of Surgeons of Edinburgh A year later he graduated M D of Edinburgh University, and subsequently, in 1880, became a Fellow of the Royal College of Physicians of London He was consulting physician to the Royal Victoria and West Hants Hospital Bournemouth, the Firs Home for Consumption and the Royal National Sanatorium for Consumption and Diseases of the Chest He was a Vice President of the British Medical Association, having been President in 1891 when the Association held its annual meeting at Bournemouth, and President of Council Dr Thomson was a justice of the peace for Hants and the borough of Bournemouth and an alderman of the Hants county council

DR CHRISTOPH SOCIN, assistant at the Basle Institute of Pathology, has been appointed professor of pathological anatomy and director of the Pathological Institute at Lausanne

The War.

THE CASUALTY LIST

THE following names of medical officers appear among the casualties announced since our last issue —

Killed

Lieut. A. G Dunn, R A.M C, received his medical education at Newcastle-on Tyne, and qualified in 1903 Prior to joining up he was in practice at Newcastle-on Tyne, and held an appointment at the Royal Victoria Infirmary in that city

Died of Wounds

Capt B Woodhouse R A.M C, received his medical education at University College Hospital, London, and qualified in 1913 He joined the R.A.M C shortly afterwards, and was promoted Captain in March, 1915

Wounded

Capt A L Anthony, R.A M.C, attached Royal Warwick Regiment
Capt N J H Gavin M C R.A.M.C
Capt J S Taylor, R.A.M.C, attached Rifle Brigade
Capt R W Hodgson-Jones, R A.M C
Lieut W G McConnell, R A.M C, attached Yorks and Lancs Regiment
Lieut Col J Barkley, R A.M G
Capt W C D Maile, R.A.M C
Capt A. H. Falkner, R.A.M.C, attached Royal Lancs Regiment
Capt. L J Moir R.A.M C
Capt G W Stanley, R A.M C
Capt. P A. Doyle R.A M C
Lieut M J Macauley, R A M C
Capt L R Shore, M C, R A.M C
Capt L M Weeks, R A M C
Capt W L R Wood, M.C, R.A.M.C, attached Royal Field Artillery
Lieut H Snape R.A M C
Capt T H. Whittington, R.A.M C, attached Essex Regt
Lieut Col H Gibson R.A.M C
Capt. J Lyons, R.A.M C
Capt H. Moore M.C, R.A M.C
Capt J F W Sandison, R.A.M C

CASUALTIES AMONG THE SONS OF MEDICAL MEN

The following additional casualty among the sons of medical men is reported —

Major H S Semple, M C Royal Engineers killed in action, eldest son of Dr H F Semple, of Budleigh Salterton, Devon

THE HONOURS LIST

Clasp to the Victoria Cross

The highest award for bravery and devotion to duty in the face of the enemy has again been bestowed upon a member of the medical profession, Captain N G Chavasse who has most regretfully be it recorded, paid the supreme sacrifice The official announcement is as follows —

Capt Noel Godfrey Chavasse V C, M.C, late R A.M C, attached Liverpool Regiment

> For most conspicuous bravery and devotion to duty when in action. Though severely wounded early in the action whilst carrying a wounded soldier to the dressing station, Captain Chavasse refused to leave his post, and for two days not only continued to perform his duties but in addition went out repeatedly under heavy fire to search for and attend to the wounded who were lying out During these searches, although practically without food during this period, worn with fatigue and faint with his wound, he assisted to carry in a number of badly wounded men over heavy and difficult ground By his extraordinary energy and inspiring example he was instrumental in rescuing many wounded who would have otherwise undoubtedly succumbed under the bad weather conditions. This devoted and gallant officer subsequently died of his wound.

Captain Chavasse was the younger of the twin sons of the Lord Bishop of Liverpool, and was educated at Liverpool College and at Oxford qualifying in 1912. His death from wounds was recorded in THE LANCET of August 18th (p 259) whilst the awards of the M C and of the V C were recorded in our issues respectively of Jan. 22nd 1916 (p 215) and of Nov 4th 1916 (p 806)

The following promotions of and awards to medical officers are also announced —

To be Brevet Lieutenant Colonel

Major (temp Lieut Col) R M Carter, I.M S

Distinguished Service Order

Temp Capt Lewis Anderson, R.A.M C

> For conspicuous gallantry and devotion to duty He carried out his duties for 48 hours without relief attending to over 100 cases and working under the most adverse conditions He was exposed throughout to intense and heavy fire of shell and gas shells, which rendered it necessary for him to work in a mask. The following night after his battalion had been withdrawn he returned to search for wounded in the front line which was still in close contact with the enemy and after working for several hours under heavy shell fire he collected and evacuated all his wounded having displayed magnificent devotion and the utmost contempt for danger throughout.

Capt (Temp Lieut Col) Norman Cecil Rutherford, R.A.M C

> For conspicuous gallantry and devotion to duty when in charge of an advanced dressing station He worked continuously under heavy shell fire evacuating the wounded from the forward area, and it was owing to his splendid example of devotion that the work was efficiently carried out.

Major Robert Archer Lloyd, I M S

Lieut (temp Capt) Arthur Frederick Isbell Patterson, R A M C

Military Cross

Capt John Ernest Affleck, Canadian A.M C

> For conspicuous gallantry and devotion to duty He crawled along a shallow and much-exposed trench to rescue a very severely wounded officer whose life depended upon an immediate operation. With the assistance of a stretcher bearer he managed to get the wounded man out on a blanket to a place where he could be evacuated. The task was a very slow and dangerous one by reason of their being completely exposed to enemy snipers, but Capt Affleck did not hesitate to risk his life in order to do all that was humanly possible for this wounded officer

Capt John Arthur Bell, R A.M C

> For conspicuous gallantry and devotion to duty during a heavy bombardment He proceeded along a road which was exposed to the most intense shell fire in order to attend to four wounded officers. He dressed their wounds and remained with them until they were evacuated by motor ambulance which was only accomplished with the greatest difficulty owing to the heavy shelling His absolute disregard of danger and devotion to duty amidst terrific shell fire were exceptionally splendid and beyond all praise

Capt John Bernard Cavenagh, R A.M C Spec Res

> For conspicuous gallantry and devotion to duty when in charge of bearers. He exposed himself to shell fire for 48 hours with splendid fearlessness, keeping all the time in touch with aid posts in the captured line, thereby ensuring a rapid evacuation of the wounded.

Capt Clarence Hamul Denver, R.A.M C

> For conspicuous gallantry and devotion to duty when in command of divisional bearers It was due to his fearless and capable handling of his party that the evacuation of the wounded was carried out with rapidity and success

Temp Capt Charles Dickson, R.A.M.C

> For conspicuous gallantry and devotion to duty when in charge of an advanced dressing station Under an intense high-explosive and gas shell bombardment the building was partially wrecked and the patients were in danger of death from gas-poisoning He at once personally organised a working party to replace the anti gas screens and take other precautions for the safety of the wounded this necessitated working in the open under extremely heavy fire, during which his total disregard of safety set a most inspiring example to his men By his energy and devotion the lives of many badly wounded men were saved

Temp Capt Charles Dundee, R A.M C

> For conspicuous gallantry and devotion to duty He worked for three days, bandaging the wounded under fire and successfully evacuating every case in his battalion almost as soon as they occurred Over 500 cases passed through his hands, and he displayed a splendid spirit of energy and devotion.

Temp Lieut David Hammond Fraser, R A.M C

> For conspicuous gallantry and devotion to duty Whilst his battery was under very heavy gas bombardment a shell wrecked the officers mess dug-out and buried two officers and five men Lieut Fraser helped by a corporal, most gallantly assisted to rescue the buried men and restore respiration, entering the dug-out several times until he eventually collapsed from the gas. On recovering consciousness he again attempted to enter the dug-out, but was prevented from doing so Later he collapsed again and remained unconscious for a long time It was due to his promptness and energy that no more than two of the gassed men succumbed.

Temp Capt Augustus Joseph Hickey, R.A.M C

> For conspicuous gallantry and devotion to duty when in command of an advanced dressing station He worked with the utmost energy and disregard of danger for 48 hours under shell fire during which time he passed through more than 700 wounded His skill and devotion saved many lives

Temp Capt William Bird Loveless, R A.M C

> For conspicuous gallantry and devotion to duty in tending the wounded under heavy shell-fire Although wounded in the face early in the day he did not leave his post, but continued with his work until he came out of action with his battalion, displaying splendid keenness and devotion to duty

Temp Capt Anthony John McCreadie, R A M.C

For conspicuous gallantry and devotion to duty under heavy shell fire and in most trying circumstances He worked alone and incessantly for 36 hours in the open attending to the wounded and on two occasions he carried men under cover and dressed them He evacuated all the wounded with admirable rapidity and efficiency and his coolness and disregard for personal safety under fire afforded a magnificent example to all ranks He has displayed similar gallantry on other occasions

Capt John Morrison Milne, R A.M C

For conspicuous gallantry and devotion to duty When a dug out containing combustion products was blown in and the inmates buried he procured oxygen cylinders and played them into the dug-out thereby saving their lives He also assisted most untiringly in digging out the men, who owe their lives to his promptness and gallantry under heavy shell fire

Temp Capt Samuel Ernest Picken, R A M C

For conspicuous gallantry and devotion to duty in going forward under heavy shell fire and attending to the wounded in advanced trenches and shell holes He remained in the shelled area for a long period working incessantly and efficiently at the dressing and evacuation of the wounded He has always shown the same gallant spirit and devotion to duty

Capt James Calvert Spence, R A.M C , Spec Res

For conspicuous gallantry and devotion to duty in proceeding to a battery that was suffering heavily from intense enemy shell fire, and continuing to search blown in dug outs and tend the wounded under heavy fire He displayed exceptional coolness and gallantry on this occasion and on many previous occasions he has carried out his duties with magnificent devotion

Temp Capt Hugh Frederic Wickens, R A.M C

For conspicuous gallantry and devotion to duty in attending to the wounded whilst the camp was being heavily shelled The dressing station was totally unprotected and when it was eventually destroyed by enemy shell fire he showed splendid initiative and coolness in re-establishing his station elsewhere continuing to clear the wounded and do his work in the most gallant and devoted manner He has on several previous occasions displayed conduct of the same high order

---

The names of the following medical officers have been brought to the notice of the Secretary of State for War for valuable services rendered in connexion with military operations in the field —

Capt W B Marshall M C, R A.M C Maj W McConaghy R A M C

MEDICAL BOARDS FOR FUNCTIONAL NERVOUS DISORDERS

We publish elsewhere an advertisement from the Ministry of Pensions, Westminster House, Millbank, inviting applications from registered medical practitioners in the counties of Westmorland, Lancashire, and Cheshire to serve on medical boards for the examination of, and the assessment of pensions for, men discharged from the Army for neurasthenia and functional nervous disorders We hope that the medical practitioners who are able to carry on this valuable work—it is suggested that the time required will not exceed five hours per diem—will make their applications promptly, stating the number of days per week on which their services will be available Our readers will, we know, approve of this sensible manner of obtaining assistance for purposes arising out of the war from medical men still in civilian practice

THE EMPLOYMENT OF AMERICAN PRACTITIONERS IN MILITARY HOSPITALS

We noted last week briefly the fact that in certain commands it had been decided to supersede British civilian practitioners serving with the forces by American medical men. In this way more British practitioners would be available to meet the pressing home needs which have been made clear by the work of the Central Medical War Committee But that committee has received no indication that a general policy of substitution has been prepared by the War Office, and in the absence of any organised plan it is certain that considerable muddle will ensue and justifiable chagrin be caused.

In all areas the American practitioners can be quite certain of finding on the part of their British colleagues a warm welcome. No feelings of resentment aroused by abrupt dismissals can possibly be directed against our professional colleagues and military allies, who for their part can only feel regret if they find themselves in places where their services are not urgently required when at other places the reverse position maintains We presume that the War Office will take counsel with the Central Medical War Committee sooner or later, because that body possesses all the detailed information necessary to say where a shortage of civilian medical practitioners is being felt, and therefore where most valuable relief could be afforded by the drafting into the war hospitals of American practitioners But it is a pity that some such coöperation between the War Office and the Statutory Professional Committees did not take place before active substitution commenced Already at several centres civil practitioners who for small emolument have done first-class work at military hospitals, have been suddenly sent back to their civilian practices, though for the conduct of those practices they had made proper arrangements in their absence, so that the community in which they practised was undergoing the minimum of inconvenience. Naturally this position is deeply felt by those officers while the unpleasantness could have been avoided by clear information to all concerned on what principle the substitution was being made.

It is clear that the training which they will receive in the war hospitals will be valuable to the American practitioners but this training might have been secured for them more effectively on some plan of dilution, under which some of those who had been discharging the duties previously would have remained at their places for the assistance of the new men drafted in According to this plan the reinforcement of the supply of practitioners could and would have been directed to the areas where it was urgently needed Economy would in this way have been effected by increasing gradually the number of whole-time men, but the services of many of the civilian practitioners who have been working at military hospitals have not been remunerated on such a scale that economy can play any great part in the action so far taken by the War Office We hope that before it is too late the War Office will decide to use the services of American practitioners upon some intelligible principle which will secure for the medical officers of our allies the advantages of proper training and for this country additional medical service in those areas—all well known to the Central Medical War Committee—where the need is felt

---

THE WAR RECORD OF THE LONDON MEDICAL SCHOOLS THE THIRD YEAR OF WAR.

An inquiry into the war record of the larger metropolitan medical schools a year ago resulted in obtaining some interesting figures which were published in THE LANCET of Sep 23rd 1916 p 579 We are now able to complete some of these figures to include the third year of war but the records cannot possibly be entirely up to date The deans of all the schools desire to be kept closely informed of the records of their men who are serving in the Navy and Army Those schools which have furnished returns are given in alphabetical order —

St Bartholomew's —From Sept 1st 1916 to August 25th 1917 231 joined the Army and 40 joined the Navy 12 were killed in action 7 died on service 4 were drowned 4 died of wounds 33 were wounded 1 was missing and 4 were prisoners (of whom 2 have been exchanged) Mentioned in Despatches Army 138, Navy 2. Honours K.C.M.G., 1, C.B., 5, C.S.I., 1, C.M.G., 6, D.S.O. 12, Bar to Military Cross, 3, Military Cross, 32 D.S.C. 1, Knight of Grace of St John of Jerusalem, 1, Kaisar-i-Hind Medal, 1 Serbian Order of White Eagle (2nd Class 1, 4th Class 1 5th Class 4), 6, Legion of Honour, conferred by the French Republic, 2, Order of St Stanislas (2nd Class) 2, Officer of the Order de la Couronne, conferred by the King of the Belgians 1, Officer Military Order of Savoy, conferred by the King of Italy, 1 Promotions for valuable services at home, 12, Territorial Decoration 2 The completed numbers for the three years are therefore Joined, 1746 Died on Service, 65

St George's —The completed figures are Joined, 299 Died on service 8 (of whom 6 were killed), wounded, 10, Prisoners 2 Honours C.M.G 4, D.S.O., 5, M.C., 6, C.B., 2, Mentioned in Despatches, 40

King's College —The completed figures are Joined, 269 Died, 16 Honours K.C.B., 1, K.C.M.G., 3, K.C.V.O., 1, C.B., 3, C.M.G 5, Military Cross 8, D.S.O., 8, Mentioned in Despatches, 29 Legion of Honour (Grand Officier), 1, Commandeur de l'Ordre de Leopold, 2

London —The completed figures are Joined, 1278 Died 72. Honours K.C.B., 1 C.B., 3, C.M.G 8, D.S.O., 17, Knighthood 1, D.S.C., 2, Bar to Military Cross, 1, M.C., 59 Military Medal 2 Knight of Grace of St John of Jerusalem 1 Legion d'Honneur (Croix de Guerre), 1, Croix de Chevalier, 1 Order of the Crown of Italy, 1, Order of St Anne 3rd Class (with Swords), 2, Chevalier de l'Ordre de Leopold 1 Officier de l'Ordre de la Couronne, 1, Medal of St George (Russian) 1 Order of St Vladimir (Russian) 1, Order of the White Eagle 1, Mentioned in Despatches, &c., 110, Commended for services by Secretary of State for War 10

St Mary's —The completed figures are Joined 484 Died, 31 Honours C.B 3 C.M.G., 6, M.C., 11, D.S.O., 17, C.V.O 1 Order of the White Eagle 4th Class (with Swords) (Serbian) 1, Ordre de la Couronne (conferred by the King of the Belgians) 1 Legion d'Honneur (Croix de Guerre) (conferred by the President of the French Republic) 1, Order of St Sava, 5th Class Serbian) 1, Silver Medal for Valour (Italian) 1 Mentioned in Despatches 73, Promotions for valuable services at home 12, Wounded, 29, Prisoners of War 7 (of whom 4 have been exchanged), Missing 10

Middlesex —The completed figures are Joined, 428 Died, 22. Honours 29

St Thomas's —The completed list up to August 8th is as follows Joined 972 Died 39 Honours V.C., 1, K.C.B 1, K.C.M.G 2 C.B., 4, C.M.G., 11 M.V.O. 1, D.S.O 16 M.C 23 Bar to M.C 1, Mentioned in Despatches and for valuable service 101 men, 146 times, Order of the Hospital of St John of Jerusalem, 3 The foreign honours include French, 4, Serbian, 4, Belgian, 2, Egyptian, 1

University College Hospital —The completed figures are Joined 682 Died, 20 Honours K.C.M.G., 1, C.M.G., 14, C.B 4 D.S.O. (Bar 1) 10, V.C. (Clasp), 1, Legion of Honour (Croix de Commandeur), 1, Croix de Guerre, 2, Military Cross 12 First Bar to Military Cross, 3 Second Bar to Military Cross 1 Mentioned in Despatches (16 twice 2 three times) 102, Order of the White Eagle, 4th Class, with Swords (Russian) 1 Order of St Stanislas, 2nd Class, with Swords (Russian), 1

WAR DRAWINGS

The publishers of *Country Life* have now issued the first and second parts of War Drawings[1] executed in France by Lieutenant Muirhead Bone, and destined for the British Museum Each part will contain reproductions in one, two or more colours according to the character of the originals, and the low price has been fixed by the Government so that the publication as a whole, or in the form of separate plates, may have as wide a circulation as possible. Further particulars will be sent on application to the publishers

Part I contains among its ten drawings, several notable pictures amongst others a sympathetic portrait of Sir Douglas Haig a view of distant Ypres and one of the ruins of the famous Cloth hall and an admirable drawing of the lovely cathedral at Amiens round whose fleche the aeroplanes are careering like birds This picture is reminiscent of Mr Muirhead Bone's well known work as an etcher but public interest will probably centre upon his terrific drawing (Plate 7) of tanks going into action The centre of the illustration is occupied by an immense tank, jolly and terrible rolling off on its furious mission, and the plate is sure to become popular for framing

---

[1] War Drawings. By Lieutenant Muirhead Bone Parts I and II., price 10s 6d. each net The series of six parts in portfolio £3 3s. net separate plates 2s 6d. each 1917 Published by authority of the War Office from the offices of "Country Life" Limited, 20 Tavistock street, Covent Garden London

Part II also contains ten plates, and all the drawings are characterised by the same vigour, love of truth, and sense of the picturesque and dramatic To our mind the most effective drawing in this series is Plate 14, showing the point of the River Somme, near Corbie, in which a wonderful colour effect is got by the use of a bright brown wash shaded with grey on a white ground Plate 20, "Erecting Aero planes," is in a completely different style Here in the portrayal of the rafters of the workshed and of the number less pulleys with their running bands, and of the tressels supporting the aeroplanes in *construction*, Mr Muirhead Bone has given full play to his love of patterns made by criss-cross lines, a love he so fully displayed in his famous etching of Charing Cross railway station under repair The drawing is richly tinted and elaborate, though simple, and creates its intended impression of intense activity coupled with business organisation We recommend these publications to our readers

BLINDED SOLDIERS' CHILDREN —Sir Arthur Pearson has issued a letter to the press saying that the success of the work at St Dunstan's has exceeded his most sanguine hopes He now feels that everything possible should be done to encourage the bachelor blinded soldiers to marry and surround themselves with children, and also to help those already married with their new babies who may arrive Joy will be brought into the soldiers' lives, a wife is a practical help to a sightless man, and the Empire will want the sons and daughters The Government makes a weekly allowance for children born before or within nine months of the soldier s discharge But there is, of course, no allowance for the children born later or for men who marry after leaving the Army because of their disablement Sir Arthur Pearson hopes to be able to raise a fund to provide an allowance of 5*s* per week until the age of 16 for each of these children who are not cared for by the State The total required, he thinks, will certainly amount to, and may even exceed, £250 000, and he enjoins on readers of this announcement to subscribe themselves and to help in collecting for this fund To the women of this country he is sure the object will particularly appeal. Requests for information and donations should be sent to Sir Arthur Pearson, 224, Great Portland street, London, W 1, the envelope being marked "Blinded Soldiers Children Fund"

THE IVORY CROSS —A meeting of those interested in the welfare of the dental profession and the Ivory Cross will be held at 31 and 32, Bedford street, Strand, W C, to day (Saturday, Sept 22nd), at 3 o clock prompt, when the memorandum and articles of association passed by the Board of Trade will be presented for the consideration of the dental profession

BETTER ARTIFICIAL LIMBS FOR SOLDIERS — Mr John Hodge, Minister of Pensions, presiding at a dinner held at the Trocadero on Sept 13th, said that the outstanding ideal before the Pensions Ministry was not the allotment of pensions so much as the restoration to useful citizenship of mutilated, wounded, and suffering men Wherever possible an endeavour would be made to restore men to the full use of their limbs, and he was seeking money from the Treasury for the purpose of starting a National Experimental Laboratory where we might get as near as possible to perfection in artificial limbs He desired to call to his aid the greatest skill and the greatest inventive faculty that the country possessed in order to get the best artificial limb possible In conclusion, he paid a high tribute to the medical profession, the greatness of whose work, he said, in the direction of restoration was beyond conception Incidentally, he mentioned that there were 900,000 pensioners on the books of his Department, and that this number was being increased by hundreds every week

At a private deputation on Sept 17th from the Roehampton Hospital Committee regarding the proposal to establish a National Experimental Laboratory for the purpose of designing and controlling the manufacture of artificial limbs for disabled soldiers, Mr Hodge reiterated his intention of taking immediate steps to seek the necessary funds for the establishment of a National Experimental Laboratory which might ultimately become a national factory for manufacturing limbs For the present he was opposed to the establishment of a national factory It was essential that the committee of management of the National Laboratory should be small, representative of surgeons and mechanical experts, and distinct from any committee managing hospitals for limbless men The laboratory committee would be directly responsible to the Ministry of Pensions

"WHAT EVERY SOLDIER SHOULD KNOW"—Some months ago the Military Hospitals Commission of Canada issued a poster giving information to the disabled soldier in regard to the possibilities of earning his own living, and setting out exactly what is being done for him in the way of pensions and the free supply of artificial limbs Under the title "What Every Soldier Should Know," this information is now being reprinted on a card about the size of a court-shaped envelope, and the cards are being widely distributed. A leaflet for civilians as well as soldiers is also being circulated in the form of a conversation with Private Pat, who says "I'll take whatever pension my old leg's worth, but blamed if I want to *live* on one, and *rust* away the rest of my life I want to be a man again as I was before, and make my own living, not sponge on other people How s it going to be done? Tell me all about it" Card and leaflet answer the question for him and for the employer The spread of information of this kind must be exceedingly useful, for it is not fully realised that with modern scientific training and appliances a large number of maimed soldiers may become self supporting members of society Copies of both card and leaflet can be obtained in the United Kingdom from Canadian Red Cross representatives and at all hospitals where Canadian soldiers are undergoing treatment.

"THE LEAGUE OF MERCY"—A War Bazaar is to be held at the Ritz Hotel, Piccadilly on Oct 24th and 25th next, to augment much needed funds for the general hospitals which are daily nursing back to health many poor patients as well as our wounded brave sailors and soldiers and victims of the air raids The bazaar is being organised by the presidents and lady presidents of certain districts of "The League of Mercy" All information can be had of the League of Mercy offices, 29, Southampton street, Strand, or the honorary organising secretaries, Mr W and Miss Andrews, 5, Belsize park, Hampstead.

AMERICAN WOMEN'S WAR HOSPITAL, PAIGNTON, SOUTH DEVON —An analysed report of the fourth thousand cases treated at this hospital has been issued by Dr D Pearce Penhallow, Major in the Medical Reserve Corps, United States Army, chief surgeon to the hospital, and its administrative officer There were in the hospital on August 19th, 1916 202 patients Up to May 20th, 1917, 982 more were received, totalling 1184 *received*, *but on* May 29th, 1917, there remained in the hospital *only* 184 cases a thousand having been discharged *as follows* For invaliding, 52, transferred for special *treatment to* various hospitals, 147, transferred to convalescent hospitals (mainly the Larches V A D Hospital, *Paignton*, and Totnes V A D Hospital), 559, discharged to *furlough*, 238, and died, 4 The average time in the hospital for the total 1000 discharged was *50* days There was a *total of* surgical cases of 650 (487 traumatic and 163 non traumatic), and a total of medical *cases of* 350 (infections, 124, non infectious, 220, diseases *of the eye*, 4, *diseases of* the skin, 11, epididymitis, 1, totalling 360, but minus 10 medical complications of surgical cases) The results of the treatment of 650 surgical cases were as follows Cured, 395, improved, 243, unimproved, 10, died, 2 (shrapnel wound of skull and cerebral abscess one and gunshot wound of chest and pul monary embolism the other) The results in the 350 medical cases were as follows Cured, 120, improved, 220, unim proved 8, died, 2 (cerebro-spinal meningitis one and nephritis the other) The operations before *admission* numbered 270 and after admission 263, 2 refusing operations The location of the injuries predominated in order *as follows* Thigh, lower leg, upper arm shoulder, back, forearm, hand, buttocks, foot knee, face (These did not include a total of 163 fractures, classified as *follows* head, 15, trunk, 25, upper extremity, 63, lower extremity, 60) The cause of the injuries was Shell, 371, bullet, 125, shrapnel, 36, grenade, 25 Under the heading of Complications of Wounds—*infections—are* following numbers Pyogenic, 283, gas bacillus, 15, tetanus, 1. The eight small pages of *the report* contain the statistical results of a large amount of good work.

Medical News.

THE WELFARE OF INFANCY —From Oct 1st to Dec 17th, on Mondays, from 5 30 to 6.30 P M , a course of elementary lectures on infant-care for mothers, teachers, infant-welfare workers, and others will be held at 1, Wimpole-street, W , under the auspices of the National Association for the Prevention of Infant Mortality The lecturers include Mr C F P Baly, Lady Barrett, Mr E A Barton, Dr Mildred Burgess Dr S Gilford Dr W J Howarth, Mr H R Jeremy, Dr Eric Pritchard, Dr Flora Shepherd, and Mr Hunter F Tod. The fee for the whole course of 12 lectures will be 5s , and for a single lecture 1s For tickets, which must be obtained in advance, application should be made to Miss Halford Secretary, National Association for the Prevention of Infant Mortality, 4, Tavistock square, London, W C

CERTIFICATES AS TO THE EYESIGHT AND HEARING OF "FIREMEN, EXAMINERS, OR DEPUTIES" EMPLOYED IN MINES UNDER THE COAL MINES ACT —The Home Secretary desires to draw the attention of medical practitioners in colliery districts and elsewhere to the provision in Section 15 (1) (c) of the Coal Mines Act, 1911, which requires that a person holding a certificate of qualification as a fireman, examiner, or deputy must subsequently, so long as he continues to be employed as a fireman, examiner, or deputy obtain every five years from a school, institution or authority approved by the Secretary of State, or from a duly qualified medical practitioner, a fresh certificate in the prescribed form to the effect that his eyesight is such as to enable him to make accurate tests for inflammable gas and that his hearing is such as to enable him to carry out his duties efficiently

THE LATE MR ARTHUR BADCOCK.—The death of Mr Arthur Badcock, of York occurred on Sept 16th, suddenly, though it was preceded by an illness of some months' duration Mr Badcock was the son of the late Rev J Badcock, D C L , vicar of Stroud and after completing his studies at the Leeds School of Medicine was appointed resident medical officer to the York Dispensary Subsequently he settled in practice in York, and became honorary medical officer to the Dispensary of which for some years he has been senior honorary officer He took a keen interest in its management and in all professional matters in the city and from July, 1914-1917, was President of the York Medical Society He was held in high esteem by his medical colleagues and by a wide circle of friends and patients

THE MEDICAL DEFENCE UNION —At the annual general meeting of the Medical Defence Union the chair was taken by the President Sir John Tweedy who was re-elected President for the ensuing year We have received a copy of the report of the council, which, as usual, forms interesting reading and testifies to the valuable work carried on by the Union, although that work has been beset by many difficulties owing to the continuance of the war Hundreds of members have had to claim urgent advice in respect of their 'joining up," owing to the consequent dislocation of medical practice, insurance and partnership agreements A great deal of extra work has thus been cast upon the Executive, and legal questions arising out of the war and the mobilisation of medical practitioners have had to be dealt with Letters asking advice have been received from members on active service from almost every part of the war arenas and it has naturally been a great satisfaction to the council—a condition of affairs upon which they may be congratulated—to know that, although thousands of miles may lie between their members and the Executive of the Union, yet, when in doubt or difficulty, the members naturally turn to the Union for help advice or assistance Certain claims by civilian medical officers for taking medical charge of troops in the absence of a military medical officer, which were held up or resisted by the Army authorities for various reasons, were placed in the hands of the Union and in every case satisfactory settlements were completed in the course of time The illegal assumption of Army medical rank, and even the holding of commissions as such by unqualified persons have been dealt with and in each case every assistance has been given to the satisfaction of the public authorities in connexion with these cases, where the prior history of the suspect was in the possession of the Executive As in former reports many cases are recorded with which the Union have had to deal during the year and they all demonstrate the benefits received by those who are members of the Union The solicitor s report also bears the impress of the war, for approximately one third of the 319 cases referred to him during the past two years had relation to the solution of partnership questions and the adjustment of matters arising out of appointments, whilst an equal number concerned questions arising under the National Insurance Act The respect in which the Union is held by those inclined to favour and support litigation of a speculative character has never been more clearly evidenced, and we congratulate the general secretary, Dr A G Bateman, and the solicitor, Mr W E Hempson, on a successful year's work

THE BIRTHDAY HONOURS —Among the recipients of the Kaisar i Hind gold medal of the first-class (see Birthday Honours published in THE LANCET of June 9th, p 885) the name of Lieutenant-Colonel K. Prasad, I M S , should have been included

WEST LONDON MEDICO CHIRURGICAL SOCIETY —The opening meeting of the session will be held on Friday, Oct 5th at the West London Hospital Dr A J Rice-Oxley, the newly elected President, will deliver an address on Medical Men as Portrayed in English Literature

THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN —The opening of the seventy sixth session of the School of Pharmacy will take place on Wednesday afternoon, Oct 3rd, when the Hanbury gold medal will be presented by the President to Professor H G Greenish, and the inaugural sessional address will be delivered by Lieutenant-Colonel E F Harrison, C M G

OFFICIAL DRAWINGS OF ADMIRALS AND GENERALS —Some months ago Mr Francis Dodd, the well known portrait painter and etcher, was given special facilities to obtain sittings from distinguished leaders in the Navy and Army Mr Dodd has completed many drawings and arrangements have been made to publish reproductions of them, with appropriate letterpress The first series will be issued shortly under the title of Generals of the British Army "

MEDICAL OFFICERS' SALARIES —The health committee of the South Shields Corporation dealt with an application from Dr D Morley Mathieson to consider the terms of his appointment as medical officer of health for the borough The committee obtained a summary of the salaries paid to medical officers in 17 towns ranging from 75 000 inhabitants to the size of South Shields (97,000), and this showed the average salary to be £686 per annum In these circumstances the committee recommends that Dr Mathieson's salary should be increased from £500 to £600

THE MEANING OF AMNESTY —The case of Mr Richard Hayes, formerly dispensary doctor at Rush and Lusk, co Dublin, has provoked in Ireland questions as to the meaning of amnesty Having taken part in the Sinn Fein rebellion, he was detained in England until at the granting of the general amnesty he was allowed to return to Ireland with others in like position He applied for reappointment to his dispensary, which had remained without a medical officer during his absence was reinstated by the board of guardians, and took up his work again Three weeks later an intimation was received from the Local Government Board in Ireland to the effect that the Board was unable to ratify his appointment because he had not yet received free pardon from the Crown

URBAN VITAL STATISTICS

(Week ended Sept 15th, 1917)

English and Welsh Towns —In the 96 English and Welsh towns with an aggregate civil population estimated at nearly 17 000 000 persons, the annual rate of mortality was 10·6, against 10·6 and 11 1 per 1000 in the two preceding weeks In London, with a population exceeding 4 000 000 persons the death rate was 9 8, or 2 1 per 1000 below that recorded in the previous week among the remaining towns the death rates ranged from 5·0 in Barrow in Furness, 5 1 in Bath, and 5 6 in Ealing to 17·2 in South Shields, 19 9 in Carlisle and 20·9 in Stockton on Tees. The principal epidemic diseases caused 351 deaths which corresponded to an annual rate of 1 1 per 1000 and included 262 from infantile diarrhœa, 39 from whooping-cough 22 from diphtheria, 18 from measles 6 from scarlet fever and 4 from enteric fever The deaths from diarrhœa, which had steadily increased from 63 to 320 in the eight preceding weeks fell to 262, and included 68 in London 21 in Liverpool, 15 each in Manchester and Leeds, and 13 in Birmingham The 633 cases of scarlet fever and 1037 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were respectively 31 above and 4 below the numbers remaining at the end of the previous week Of the deaths from all causes in the 96 towns 139 resulted from violence. The causes of 32 deaths were uncertified, of which 8 were registered in Birmingham 5 in Liverpool and 3 each in Stoke-on Trent and West Bromwich but not one in London.

Scotch Towns —The 246 deaths from all causes in Glasgow corresponded to an annual rate of 11·5 per 1000, and included 15 from infantile diarrhœa, 11 from whooping-cough 2 from diphtheria, and 1 each from measles and scarlet fever The 70 deaths in Edinburgh were equal to a rate of 11·0 per 1000 and included 1 death each from measles whooping-cough diphtheria, and diarrhœa.

Irish Towns —The 115 deaths in Dublin corresponded to an annual rate of 15·0 or 2·9 per 1000 less than that recorded in the previous week, and included 20 from infantile diarrhœa, 2 from diphtheria, and 1 from enteric fever The 91 deaths in Belfast were equal to a rate of 12 1 per 1000 and included 7 from infantile diarrhœa.

Appointments.

Successful applicants for vacancies Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub Editor not later than 9 o clock on the Thursday morning of each week such information for gratuitous publication*

Girl, D V L.R.C P & S Edin D P H. Lond D O Oxon has been appointed Ophthalmic Surgeon to the Eastbourne Eye Infirmary

Mitchell, T Carter M R C S L R C P Lond, Medical Officer of Health for the Wath Rural Council

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index)

When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor

Birkenhead Borough Hospital.—Junior House Surgeon Salary £175 per annum with board &c

Birmingham Little Bromwich Fever Hospital.—Female Assistant Medical Officer Salary £300 per annum with board &c

Birmingham (near) Romsley Hill Sanatorium —Temporary Medical Superintendent Salary £450 per annum with board &c

Brighton Royal Alexandra Hospital for Sick Children Dyke-road —House Surgeon Salary £200 per annum, with board, &c

Bristol Royal Infirmary —House Physician and House Surgeon Salary at rate of £120 per annum with board &c

Bury Infirmary —Junior House Surgeon. Salary £150 per annum with board &c.

Colmonell Parish Lower District of —Medical Officer Salary £70 per annum

Derby Derbyshire Royal Infirmary —House Physician and Casualty Officer Salary £200 per annum with board, &c

Dudley Guest Hospital.—Senior Resident Medical Officer Salary £150 per annum with board &c. Also Assistant House Surgeon Salary £120 per annum with board, &c.

Fareham Hants County Asylum.—Temporary Assistant Medical Officer Salary 7 guineas a week with board &c

General Lying in Hospital York road Lambeth —Resident Medical Officer for three months Salary £100 per annum with board

Glamorgan County Asylum Bridgend —Temporary Assistant Medical Officer Salary £6 6s per week with board &c

Hospital for Consumption and Diseases of the Chest Brompton —House Physician for six months. Salary 30 guineas.

Ipswich Auxiliary Hospital for Wounded Lattice Barn —House Physician Salary as arranged with board &c.

Leeds Public Dispensary —Resident Medical Officer Salary £200 per annum with board &c

Lindsey (Lincolnshire) County of the Parts of —Assistant Medical Officer Salary £350 per annum

London County Asylum Bexley Kent —Temporary Assistant Medical Officer Salary 6 guineas per week with board &c

London Throat Hospital, 204, Great Portland street W —House Surgeon Salary £75 per annum

Manchester Education Committee.—Female Assistant School Medical Officer unmarried Salary £300 per annum

Nottingham General Hospital.—Female House Surgeon for six months Salary at rate of £250 per annum with board &c

Nottingham and Midland Eye Infirmary —Female House Surgeon Salary £200 to £250 per annum with board, &c.

Portsmouth Royal Portsmouth Hospital.—House Surgeon for six months Salary £250 per annum with board &c.

Prince of Wales s General Hospital, Tottenham, N —Honorary Anæsthetist once a week Salary £2) per annum.

Queen s Hospital for Children Hackney road, Bethnal Green E —House Physician for six months Salary £100 per annum with board &c Also Temporary Assistant Physicians for Monday afternoons and Saturday mornings. Salary at rate of £25 per annum with lunch

Rotherham Hospital.—Junior House Surgeon. Salary £150 with board &c.

Royal Berkshire Hospital —Senior Resident Medical Officer Salary £350 per annum with board &c. Also House Surgeon for six months Salary at rate of £250 per annum with board &c. Also Second House Surgeon for six months Salary at rate of £?00 per annum if qualified (if unqualified £150) with board &c

St Helens County Borough —Temporary Assistant Medical Officer of Health Salary £350 per annum

Salisbury General Infirmary —House Surgeon Salary £150 per annum with board &c

Scottish Women s Hospitals —Female Radiographers for Units in Greece Salary £300 per annum with uniform board, &c

Sheffield Royal Infirmary —Two House Surgeons Salary £120 per annum with board &c

Southampton, Free Eye Hospital.—House Surgeon Salary £100 per annum, with board &c.

Southampton Royal South Hants and Southampton Hospital. —House Physician

South London Hospital for Women South Side Clapham Common S W —Female House *Physician and House Surgeon* for six months Salaries at rate of £100 per annum each with board &c. Also Anæsthetists for Monday and Tuesday afternoons and Tuesday and Friday mornings Salary 10s 6d per attendance

Swindon G W R Medical Fund Society —Medical Officer Salary £500 per annum

West Bromwich District Hospital.—Senior House Surgeon, unmarried Salary £160 per annum with board &c.

Westmorland Lancashire, and Cheshire Counties —Medical Practitioners to serve on Medical Boards for examination of and assessment of pensions for men discharged from the Army for Neurasthenia and Functional Nervous Disorders Salary 3 guineas per day

Births, Marriages, and Deaths.

BIRTHS

Aldis —On Sept 13th at Norton House King s avenue Clapham Park the wife of Carlyle Aldis Captain R.A.M C of a son

Goffe.—On Sept 15th at a nursing home in London, the wife (*née* Edna Mary Powell M.B, B S Lond) of E G Leopold Goffe, M.D, B S Lond of a son

Guthrie.—On Sept. 13th at Greta Heswall Cheshire *the wife of* Thomas Guthrie M.B, F R C S of Rodney street, Liverpool of a son.

Reynell.—On Sept 12th, at New Cavendish street, W to Dr and Mrs W R Reynell—a son

Richmond —On Sept. 10th at Alexandria, the wife of Captain Arthur E Richmond R A M.C of a son

Tayler —On Sept 13th at Lovemead House, Trowbridge, the wife of F E Tayler M R.C S of a son

MARRIAGES

Dale—Crossland —On Sept. 11th Captain Aston Ridley Dale M C R A.M C (S R.), to Janet (Jennie) Wemyss second daughter of the late Lewis Crossland and Mrs Crossland of Leeds

Harvie—Metford —On Sept 12th at the Parish Church Kingsdown Deal Montague Harvie R.A.M C to Dorothy Isabel only daughter of Mr and Mrs E Seymour Metford of Kingsdown

Humphry—Purvis —On Sept. 14th, by special licence, Alexander Murchison Humphry (temp Major R A.M C) to Vida, youngest daughter of Mr and Mrs David Purvis Knockdown Park Belfast

Meakin—Gascoigne.—On Sept. 15th at St. Mary s Tansor Northants, Captain Leslie Meakin R.A.M C to Honor youngest daughter of the Rev W B Gascoigne M A., rector of Tansor and Mrs Gascoigne.

Moodie—Cochrane.—On Sept. 12th at the Station Hotel Perth, Alexander Reid Moodie Captain R A.M C (T) to Emily (Queenie) younger daughter of Andrew Cochrane of Craigisla, Alyth

Radford—Lloyd —On Sept 15th at Hampstead Maitland Radford M B B S son of Mr and Mrs Ernest Radford of 32, Well Walk Hampstead N W to Muriel Ann Lloyd M.B B S D P H. second daughter of Dr and Mrs Henry Lloyd, of Arsyllis St. Asaph North Wales

DEATHS

Badcock.—On Sept 16th at Clarence House York, Arthur Badcock, *M R C S L R C P aged 55 years*

Frankling —On Sept 14th 1917 at 19 York road Harrogate Florence (*née* Ashmall) wife of Herbert Frankling Was interred at Harlow Cemetery, Wednesday Sept 19th.

N.B —A fee of 5s is charged for the insertion of Notices of Births, Marriages, and Deaths

Notes, Short Comments, and Answers to Correspondents.

SACCHARIN

THE question of the harmfulness or otherwise of saccharin has recently been raised anew In THE LANCET of Nov 17th, 1888, we published a long letter from Dr C Fahlberg, who, after describing himself as the discoverer of saccharin, said that—

> If saccharin could be proved injurious to man I would ask your readers to accept my assurance that I would not be responsible for the manufacture of another ounce "

At the end of his letter he says —

> The attacks upon saccharin have sorely disquieted the public mind. If they are merited the anxiety is justified If not it will unfairly prejudice my discovery which after all will confer as much benefit upon humanity as upon myself In this spirit I ask your readers no longer to observe that silence which in most cases but not in this is both dignified and necessary It is no question of advertisement I have been grievously attacked and I plead for justice."

In the same issue of THE LANCET we published an article by Dr Thomas Stevenson and Dr L C Wooldridge, giving the results of scientific experiments made by them with saccharin Their summary is as *follows* —

> We conclude that: (1) saccharin is quite innocuous when taken in quantities largely exceeding what would be taken in any ordinary dietary (2) saccharin does not interfere with or impede the digestive processes when taken in any practicable quantity and (3) our personal experience is that saccharin may be taken *for* an extended period without interfering with the digestive and other bodily functions Hence there is no reason to think that its continued use is in any way harmful

Dr F W Pavy wrote a letter to THE LANCET of Nov 3rd, 1888, saying that—

> ' A scare has been started against saccharin upon the ground of hurtful effects having been observed to follow its employment and I have been falsely represented as participating in this assertion Under such circumstances, to remain silent would give sanction to *the statements that have been circulated.*"

This followed an annotation in THE LANCET, reporting that several paragraphs had appeared in various journals referring to the report of a commission of Paris doctors and *their adverse verdict* The conclusions of this commission were communicated to the Academy of Medicine in Paris in July, 1888 It was a communication made to the same academy by Dr Jules Worms on the subject of saccharin early in 1888 (reported in THE LANCET of May 5th, 1888) which caused the Prefect of Police of Paris to request the Council of Hygiene to give its opinion as to whether the use of this substance in alimentation would be productive of danger to the public health In England in 1888 an order was issued prohibiting its use in brewing, and from time to time in various countries it has been considered as an "adulteration" In the beginning of 1912 a United States Government Board decided against the use of saccharin because its use instead of sugar in preserved foods meant that they therefore contained less food value, saccharin lacking the nutriment of the sugar This was reported in THE LANCET of March 23rd, 1912 A few cases have been reported where saccharin apparently caused stomach pain and neuralgia and other discomforts but there is no great amount of evidence at hand as to its harmfulness when compared with the testimonials as to its benefits

A SPECIALIST IN ELECTRO THERAPY

WE have received from a correspondent a communication entitled " re A. Vernon Ward (Consolidated) Limited, enclosed within which is an application form for cumulative preference shares in a company of that name The document states that there is an insistent demand for the Vernon Ward treatment in various parts of the country and in a "brief résumé of the work already accomplished" adds that ' treatments have been administered with signal success to Royalty, members of the *Peerage* and a large number of naval and military officers and men" and also that Mr Vernon Ward enjoys the coöperation and support of the cream of the medical profession in this country " It is further stated that the goodwill of the undertaking, " created by advertising in the press to the extent of some £25,000 has made necessary the formation of the company We recommend any of our readers, including that cream of the medical profession alluded to in the circular communication, to suggest to those of their patients who may receive invitations to become shareholders in A. Vernon Ward (Consolidated) Limited, that before applying for shares and making deposits on their applications, they should take the usual course of examining the security offered and they might also ascertain who are the medical authorities whose supervision would be required to give scientific stability to any undertaking of the sort

HEARSON'S INCUBATORS

THE new list which Messrs Chas Hearson and Co, Ltd (235, Regent-street, W 1), have issued contains a large number of thermostats available for a variety of purposes, all of them regulated by means of the sensitive hollow capsule which renders possible the attainment of a temperature constant within 1° F over an indefinite period of time without adjustment Apart from this invention, the utility of which has been assured by experience in important laboratories all over the world, a new *electric incubator* is listed in which the usual water jacket is replaced by coils of electric resistance wires Naturally, with this method of heating the requisite interior temperature is rapidly reached, it is *also more economical of heat*, since it admits of a thicker layer of heat-insulating material without unduly increasing the size of the apparatus It is claimed that the same system of heating is equally applicable to drying ovens and sterilisers With a view of making the apparatus available for all countries, the list contains a preface in English, German, French Spanish, and Russian as well as a key in each language to every description of apparatus Besides thermostats, other large laboratory apparatus, such as shaking machines, centrifuges, and autoclaves, are included, and for the assistance of the novice a list of apparatus and materials suitable for the equipment of a small laboratory The list will repay careful study

ATTITUDES IN READING

THE posture of the body in writing has received for many years a large amount of attention from parents, schoolmasters, scientific observers, and medical men, but not so much attention has been paid to the posture of the body in reading In these days of many wounded men the posture of the body in reading should receive more attention The disposition of the trunk, head, and neck, and the arrangement of the limbs must have considerable influence for good or evil, particularly when the body and limbs are maintained in one position for hours at a stretch Especially is this the case when reading a book of absorbing interest, where the reader "gets lost" for a *long* time, all his attention being concentrated on what he reads Eventually he wakes up as it were from a dream in a state of rigidity and tension, to find his neck aching and his body stiff and an arm or leg all *tingling* with "pins and needles"

The attitudes of readers vary considerably Some will sit straight upright, some will lean back, and others will lean forward, propping the *forearms* across the thighs, or place the chin in the right hand and lean the elbow on the thigh If sitting on a chair some will lean forward, placing the hands behind and hanging on to the back of the chair like a *fruit bat* If sitting on an armchair some will lean for a long spell over the left arm of the chair and others over the right arm of the chair, making the ribs ache Not a few will dig their chins into their chests and curve their bodies into the form of a note of interrogation, Such an attitude maintained for a length of time is most injurious As regards the manner of holding the book, some are chin readers' and others lap readers and the book is held so that the page is at all angles The page may lie horizontally or have a dip at top or bottom or be held almost perpendicularly whilst reading the condition, of eyesight generally dictating the pose This should not be lost sight of by parents, and it is often quite useful to the practitioner to have seen his patient, especially his youthful patient reading

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention should be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, *and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification*

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot undertake to return MSS not used

Offices 423, STRAND, LONDON W C 2.

MANAGER'S NOTICES

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423 Strand, London, W C 2, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c , should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

TO COLONIAL AND FOREIGN SUBSCRIBERS

Subscribers abroad are particularly requested to note the rates of subscriptions given on page 6

The Manager will be pleased to forward copies direct from the Offices to places abroad at the rates shown, whatever be the weight of any of the copies so supplied

Notes
ON
MALARIA
FOR OFFICERS AND MEN [1]

BY CUTHBERT CHRISTY, M B, C M EDIN,
MAJOR, R.A.M C (T)
ADVISER FOR MALARIA AND TROPICAL SANITATION GENERAL HEADQUARTERS EAST AFRICAN EXPEDITIONARY FORCE.

LARGE portions of South Africa are free from malaria, or were before the war and many South Africans know nothing of the disease Men of the Cape and Rhodesian regiments who had seen service in German South West Africa and knew only one enemy, found that in coming to East Africa they were strong men no longer but had another and unseen enemy to contend with who was stronger than the Hun

Tropical East Africa is by no means an unhealthy region as regions go in the tropics, not nearly so malarial, in fact as most parts of tropical West Africa Persons who libel the climate of East Africa forget that malaria is a preventable epidemic disease and that the greater the number of whites in any given area the greater is likely to be the prevalence of any epidemic and the quicker is it likely to spread, while the cases owing to multiple re infection become more severe To forget these facts under the conditions of military service may mean the loss of very many men

Particularly is it necessary to remember that malaria is a preventable disease Twenty years ago the cause of malarial fever or "ague" was popularly believed to be exposure to night air, gases from decaying vegetation, or breathing the misty vapours rising from marshes and swamps Since then, however, the study of tropical medicine has advanced, and the necessity for the better security of life in the tropics especially in tropical Africa, has become more urgent, with the result that malaria, the most important of all diseases affecting Europeans in hot climates, has for many years absorbed the attention of French, Italian, and English scientists to such purpose that there is now scarcely another disease the cause, prevention, and treatment of which are better understood by those who have worked at the subject

It is therefore incumbent upon every man in a malarial region, more particularly when engaged in military operations, in order to avoid the disease, or at least to understand the necessity for the precautions imposed upon him; to be conversant with the main facts in connexion with its transmission from man to man, not only for his own sake but for that of his comrades, and in this instance the welfare and greater efficiency of the East African Expeditionary Force

With this aim in view the following facts have been collected for the instruction of officers and men

General

1 Malaria is a parasitic, infectious epidemic disease conveyed from one person to another by the agency of mosquitoes

2 The microscopic parasite causing it lives and develops in the corpuscles of the blood of man and in the body of the mosquito

3 There is no evidence to show that it can exist in any other animal or possibility of its existing free in *nature*

4 When blood containing the parasite is sucked up by the mosquito from a person recovering from an attack of fever" the parasites develop and multiply in the body of the insect and after three to five days may be injected by it through the skin into the blood of other men causing after another interval of eight to ten days all the train of symptoms known as malarial fever

Explanatory

5 *The malaria parasite* —Shortly after the mosquito bite and the arrival of the parasites in the blood stream they enter and commence development within the corpuscles

6 After an interval of a few days the parasites have so multiplied in the blood of the person bitten that an attack of fever sets in the length of the interval mainly depending upon the number of bite the number of parasites injected and the temperature prevailing

7 The fever may therefore not commence until the person is many miles from where he was bitten

8 After an untreated attack has run its course the fever subsides and the microscope no longer shows active parasites within the corpuscles but there still remain in the body two forms of the parasites:—
  (a) Latent or resting forms in the liver spleen &c.
  (b) Specialised crescentic forms in the general circulation

9 (a) The latent or resting forms retire after the attack from the general circulation and remain inactive in the liver, spleen &c until perhaps the treatment is relaxed or till such time as the resisting power of the individual is lessened by chill sun exposure, exhaustion or other cause when they may return to the circulation and again become active within the corpuscles producing a relapse and a return of the patient to hospital

10 The relapse has most of the features of the primary attack with all its train of symptoms and ill effects

11 (b) The crescentic bodies are not formed until the attack has run its course

12 They remain in the general circulation beneath the skin for weeks causing no symptoms but when sucked into the stomach of certain species of mosquitoes they at once become active, and after certain changes pass from the stomach contents into the stomach wall multiply enormously and eventually invade the salivary glands of the insect from whence they are injected during the act of sucking into the blood of man as fever-causing parasites (The mosquito has the power at the moment of sucking of injecting through a special tube in its proboscis an irritating salivary secretion probably for the purpose of preventing premature coagulation of the blood)

13 Only the crescentic bodies are capable of infecting and developing in the mosquito and not the active forms of the parasite as seen in the corpuscles during the attack

14 If after some weeks the crescentic body has not found its way to the mosquito's stomach it may die or it may retire from the general circulation to the liver or spleen; where it can remain without causing symptoms for a long period But any severe constitutional disturbance such as might be caused by the removal of the individual from a warm to a cold climate may result not only in these bodies reappearing in the circulation but in their having the power to multiply and produce a crop of active fever-causing parasites and what is known as a recurrent attack, even after the lapse of two or three years

15 As in the case of the relapse the recurrent attack has most of the features of the primary attack and anyone returning say to South Africa and suffering from a recurrent attack even in a district hitherto free from malaria and years after his return may become a danger to his friends or even the nucleus of an epidemic if the right kind of mosquito happens to be an inhabitant of the neighbourhood and if mosquito net precautions are not thorough

16. *The mosquito* —Only the female mosquito has the power of sucking blood the male subsisting upon the juice of plants fruit &c

17 Not all species of mosquitoes can convey malaria The majority of the common species are harmless (except those which transmit yellow fever, elephantiasis &c)

18 The few species which are capable of conveying it belong to the class *Anophelinæ* all of which are fragile insects not easily seen comparatively silent and whose bite leaves little irritation

19 It is therefore unwise to commit oneself to the remark so frequently heard that there are no mosquitoes in a particular place or camp without the opinion of an expert

20 All mosquitoes lay their eggs upon water and the larval and pupal stages of their life are spent in the water They wriggle to the surface periodically to breathe

21 When the pupa is ready to change into the mature insect it rises to the surface the pupa-case splits down the back the mosquito emerges and after an interval for its newly formed wings to harden it flies away

22. If a thin layer of kerosene oil be spread upon the surface of the water neither larvæ nor pupæ can get their breathing tubes to the surface and all die of suffocation a never failing and ever ready method of preventing mosquitoes hatching out of receptacles which cannot easily be emptied of water

23 Where there is no water there can be no mosquitoes

24 No other insect can convey malaria Where there is malaria there must be anopheline mosquitoes

25 It does not follow that because there are anopheline mosquitoes there must be malaria The insects though present may not have been infected and therefore harmless

26. One bite is sufficient to cause an attack and one infected mosquito may give malaria to several persons in one night

27 Those species of anopheline mosquitoes which convey malaria are not usually found away from human habitations or if found are not likely to be infected Consequently men on piquet duty or in bivouac or temporary camp although severely bitten by mosquitoes often run less risk of malaria than those in camps or hospitals on lines of communication where numbers of men who have suffered from malaria are congregated and where every anopheline mosquito is likely to be infected

28 *The mosquito net* —The segregation of the individual beneath an efficient net at night is by far the most important and effective means not only of guarding against a primary attack but of preventing infection being carried from the sick person to healthy persons

29 Owing to the development of crescentic carrier bodies after and not during the continuance of the fever the use of an efficient mosquito net is far more important to the welfare of the community after than before the attack.

30 One person or even a baby with crescentic bodies in his blood sleeping without a mosquito net or with one that is defective may be and often is the nucleus of an epidemic

31 Hence arises the danger of sleeping near a native village because in a malarial locality a large percentage of the youngest children have active parasites and crescentic bodies in their blood and yet play about without showing symptoms of fever

32. Adult natives, on the other hand in a malarial locality are not usually a danger for having suffered severely in early childhood they have acquired a partial immunity, and in consequence suffer little from malaria.

33 Strangers however from upland regions where there is no malaria not having suffered from the disease in childhood have acquired no immunity and are soon likely to be infected on reaching a malarial district at a lower level

34 Indians rarely seem to acquire any immunity and are very susceptible to malaria. Their proximity is a danger to European.

---

[1] These notes amount to an amplified syllabus of lectures delivered in the field to troops in East Africa Major Christy's practice was to lecture for half an hour and to answer questions for another half hour He obtained very encouraging results

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention should be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, *and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification*

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

ON
MALARIA
FOR OFFICERS AND MEN [1]

BY CUTHBERT CHRISTY, M B, C M EDIN,
MAJOR, R.A.M C (T)
ADVISER FOR MALARIA AND TROPICAL SANITATION GENERAL HEADQUARTERS EAST AFRICAN EXPEDITIONARY FORCE.

LARGE portions of South Africa are free from malaria, or were before the war, and many South Africans know nothing of the disease. Men of the Cape and Rhodesian regiments who had seen service in German South West Africa, and knew only one enemy, found that in coming to East Africa they were strong men no longer but had another and unseen enemy to contend with who was stronger than the Hun

Tropical East Africa is by no means an unhealthy region as regions go in the tropics, not nearly so malarial, in fact as most parts of tropical West Africa Persons who libel the climate of East Africa forget that malaria is a preventable epidemic disease and that the greater the number of whites in any given area the greater is likely to be the prevalence of any epidemic and the quicker is it likely to spread, while the cases owing to multiple re infection become more severe To forget these facts under the conditions of military service may mean the loss of very many men

Particularly is it necessary to remember that malaria is a preventable disease Twenty years ago the cause of malarial fever or 'ague" was popularly believed to be exposure to night air, gases from decaying vegetation or breathing the misty vapours rising from marshes and swamps Since then, however, the study of tropical medicine has advanced and the necessity for the better security of life in the tropics especially in tropical Africa, has become more urgent, with the result that malaria, the most important of all diseases affecting Europeans in hot climates, has for many years absorbed the attention of French Italian and English scientists to such purpose that there is now scarcely another disease the cause prevention, and treatment of which are better understood by those who have worked at the subject

It is therefore incumbent upon *every man* in a malarial region, more particularly when engaged in military operations, *in order to avoid* the disease, or at least to understand the necessity for the precautions imposed *upon him, to be* conversant with the main facts in connexion with its transmission from man to *man not only for his* own sake but for that of his comrades and in this instance the welfare and greater efficiency of the East African Expeditionary Force

With this aim in view the following facts have been collected for the instruction of officers and men

General

1 Malaria is a parasitic, infectious epidemic disease conveyed from one person to another by the agency of mosquitoes

2 The microscopic parasite causing it lives and develops in the corpuscles of the blood of man and in the body of the mosquito

3 There is no evidence to show that it can exist in any other animal or possibility of its existing free in nature

4 When blood containing the parasite is sucked up by the mosquito from a person recovering from an attack of fever" the parasites develop and multiply in the body of the *insect* and after three to five days may be injected by it through the skin into the blood of other men causing after another interval of eight to *ten days* all the train of symptoms known as malarial fever

Explanatory

5 *The malaria parasite* —Shortly after the mosquito bite and the arrival of the parasites in *the blood* stream they enter and commence development within the corpuscles

6 After an interval of *a few days* the parasites have so multiplied in the blood of the person bitten that an attack of fever sets in the length of the interval mainly depending upon the number of bites the number of parasites injected and the temperature prevailing

7 The fever may therefore not commence until the person is many miles from where he was bitten.

8 After an untreated attack has run its course the fever *subsides* and the microscope no longer shows active parasites within the corpuscles but there still remain in the body two *forms* of the parasites —

(a) Latent or resting forms in the liver spleen &c

(b) Specialised crescentic forms in the general circulation

9 (*a*) The latent or resting forms retire after the attack from the general circulation and remain inactive in the liver spleen &c. until perhaps the treatment is relaxed or till such time as the resisting power of the individual is lessened by chill sun exposure, exhaustion or other cause when they may return to the circulation and again become active within the corpuscles producing a relapse and a return of the patient to hospital

10 The relapse has most of the features of the primary attack with all its train of symptoms and ill-effects

11 (*b*) The crescentic bodies are not formed until the attack has run its course

12. They *remain* in the general circulation beneath the skin for weeks causing no symptoms but when sucked into the stomach of certain *species of mosquitoes they at once become* active and after certain changes pass from the stomach contents into the stomach wall multiply enormously and eventually invade the salivary glands *of the* insect from whence they are injected during the act of sucking into the blood of man as fever-causing parasites (The mosquito has the power at the moment of sucking of injecting through a special tube in its proboscis an irritating salivary secretion probably for the purpose of preventing premature coagulation of the blood.)

13. Only the crescentic *bodies are capable of infecting* and developing in the mosquito and not the active forms of the parasite as seen in the corpuscles during the attack

14 If after some weeks the crescentic body has not found its way to the *mosquito's* stomach it may die or it may retire from the general circulation to the liver or spleen where it can remain without causing symptoms for a long period But any severe constitutional disturbance such as might be caused by the removal of the individual from a warm to a cold climate *may result not only* in these bodies reappearing in the circulation but in their having the power to multiply and produce a crop of active fever-causing parasites, and what is known as a recurrent attack even after the lapse of two or three years

15 As in *the case of the relapse* the recurrent attack has most of the features of the primary attack and anyone returning say to South Africa and suffering from a recurrent attack even in a district hitherto free from malaria and years after his return may become a danger to his friends or even the nucleus of an epidemic if the right kind of mosquito happens to be an inhabitant of the neighbourhood and if mosquito net precautions are not thorough

16 *The mosquito* —Only the female mosquito has the power of sucking blood the male subsisting *upon the juice of plants fruit &c*

17 Not all species of mosquitoes can convey malaria The majority of the common species are harmless (except those which transmit yellow fever elephantiasis &c.)

18 The few species which are capable of conveying it belong to the class *Anophelinæ* all of which are fragile insects not easily seen comparatively silent and whose bite leaves little irritation

19 It is therefore unwise to commit oneself to the remark so frequently heard that there are no mosquitoes in a particular place or camp without the opinion of an expert

20 All mosquitoes lay their eggs upon water and the larval and pupal stages of their life are spent in the water They *wriggle to the* surface periodically to breathe

21 When the pupa is ready to change into the mature insect it rises to the surface the pupa-case splits down the back the mosquito emerges, and after an interval for its newly formed wings to harden it flies away

22. If a thin layer of kerosene oil be spread upon the *surface* of the water neither larvæ nor pupæ can get their breathing tubes to the surface and all die of suffocation a never-failing and ever ready method of preventing mosquitoes hatching out of receptacles which cannot easily be emptied of water

23 Where there is no water there can be no mosquitoes

24 No other insect can convey malaria. *Where there is malaria there* must be anopheline mosquitoes

25 It does not follow that because there are anopheline mosquitoes there must be malaria The insects though present may not have been infected and therefore harmless

26. One bite is sufficient to cause an attack and *one* infected mosquito may give malaria to several persons in *one* night

27 *Those* species of anopheline mosquitoes which convey malaria are not usually found *away from* human habitations or if found are not likely to be infected Consequently men on piquet duty or in bivouac or temporary camp although severely bitten by mosquitoes often run less risk of malaria than those in camps or *hospitals* on lines of communication, where numbers of *men* who have suffered from malaria are congregated and where every anopheline mosquito is likely to be infected

28 *The mosquito net* —The segregation of the individual beneath an efficient net at night is by far the most important *and effective* means not only of guarding against a primary attack but of preventing infection being carried from the sick person to healthy persons

29 *Owing* to the development of crescentic carrier bodies after and not during the continuance of the *fever the use of* an efficient mosquito net is far more important to the welfare of the community after than before the attack.

30 One person or even a baby with crescentic bodies in his blood sleeping without a mosquito net or with one that is defective may be and often is the nucleus of an epidemic

31 Hence arises the danger of sleeping near a native village because in a malarial locality a large percentage of the youngest children have active parasites and crescentic bodies in their blood and yet play about without showing symptoms of fever

32. Adult natives, on the other hand in a malarial locality are not usually a danger for having suffered severely in early childhood they have acquired a partial immunity and in consequence suffer little from malaria.

33 Strangers however from upland regions where there is no malaria not having suffered *from* the disease in childhood have acquired no immunity and are soon likely to be infected on reaching a malarial district at a lower level

34 Indians rarely seem to acquire any immunity and are very susceptible to malaria. Their proximity is a danger to European.

[1] These notes amount to an amplified syllabus of lectures delivered in the field to troops in East Africa Major Christy's practice was to lecture for half an hour and to answer questions for another half *hour* He obtained very encouraging results

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention should be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, *and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification*

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot undertake to return MSS not used

Offices 423, STRAND, LONDON W C 2

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W C 2, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c , should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

TO COLONIAL AND FOREIGN SUBSCRIBERS

Subscribers abroad are particularly requested to note the rates of subscriptions given on page 6

The Manager will be pleased to forward copies direct from the Offices to places abroad at the rates shown, whatever be the weight of any of the copies so supplied

ON

MALARIA

FOR OFFICERS AND MEN [1]

BY CUTHBERT CHRISTY, M B, C M EDIN,

MAJOR, R.A.M C (T)

ADVISER FOR MALARIA AND TROPICAL SANITATION GENERAL HEADQUARTERS EAST AFRICAN EXPEDITIONARY FORCE

LARGE portions of South Africa are free from malaria, or were before the war, and many South Africans know nothing of the disease Men of the Cape and Rhodesian regiments who had seen service in German South West Africa, and knew only one enemy, found that in coming to East Africa they were strong men no longer but had another and unseen enemy to contend with who was stronger than the Hun

Tropical East Africa is by no means an unhealthy region as regions go in the tropics, not nearly so malarial, in fact as most parts of tropical West Africa Persons who libel the climate of East Africa forget that malaria is a preventable epidemic disease, and that the greater the number of whites in any given area the greater is likely to be the prevalence of any epidemic and the quicker is it likely to spread, while the cases owing to multiple re infection become more severe To forget these facts under the conditions of military service may mean the loss of very many men

Particularly is it necessary to remember that malaria is a preventable disease Twenty years ago the cause of malarial fever or "ague" was popularly believed to be exposure to night air, gases from decaying vegetation, or breathing the misty vapours rising from marshes and swamps Since then, however, the study of tropical medicine has advanced, and the necessity for the better security of life in the tropics especially in tropical Africa, has become more urgent, with the result that malaria, the most important of all diseases affecting Europeans in hot climates, has for many years absorbed the attention of French, Italian and English scientists to such purpose that there is now scarcely another disease the cause, prevention, and treatment of which are better understood by those who have worked at the subject

It is therefore incumbent upon every man in a malarial region, more particularly when engaged in military operations, in order to avoid the disease, or at least to understand the necessity for the precautions imposed upon him; to be conversant with the main facts in connexion with its transmission from man to man not only for his own sake but for that of his comrades and in this instance the welfare and greater efficiency of the East African Expeditionary Force

With this aim in view the following facts have been collected for the instruction of officers and men

General

1 Malaria is a parasitic, infectious epidemic disease conveyed from one person to another by the agency of mosquitoes

2 The microscopic parasite causing it lives and develops in the corpuscles of the blood of man, and in the body of the mosquito

3 There is no evidence to show that it can exist in any other animal or possibility of its existing free in nature

4 When blood containing the parasite is sucked up by the mosquito from a person recovering from an attack of fever the parasites develop and multiply in the body of the insect and after three to five days may be injected by it through the skin into the blood of other men, causing after another interval of eight to ten days all the train of symptoms known as malarial fever

Explanatory

5 *The malaria parasite* —Shortly after the mosquito bite and the arrival of the parasites in the blood stream they enter and commence development within the corpuscles

6 After an interval of a few days the parasites have so multiplied in the blood of the person bitten that an attack of fever sets in the length of the interval mainly depending upon the number of bites the number of parasites injected and the temperature prevailing

7 The fever may therefore not commence until the person is many miles from where he was bitten

8 After an untreated attack has run its course the fever subsides and the microscope no longer shows active parasites within the corpuscles but there still remain in the body two forms of the parasites:—

(a) Latent or resting forms in the liver spleen &c

(b) Specialised crescentic forms in the general circulation

9 (a) The latent or resting forms retire after the attack from the general circulation and remain inactive in the liver spleen &c until perhaps the treatment is relaxed or till such time as the resisting power of the individual is lessened by chill sun exposure, exhaustion or other cause when they may return to the circulation and again become active within the corpuscles producing a relapse and a return of the patient to hospital

10 The relapse has most of the features of the primary attack with all its train of symptoms and ill effects

11 (b) The crescentic bodies are not formed until the attack has run its course

12 They remain in the general circulation beneath the skin for weeks causing no symptoms but when sucked into the stomach of certain species of mosquitoes they at once become active and after certain changes pass from the stomach contents into the stomach wall multiply enormously and eventually invade the salivary glands of the insect from whence they are injected during the act of sucking into the blood of man as fever-causing parasites (The mosquito has the power at the moment of sucking of injecting through a special tube in its proboscis an irritating salivary secretion probably for the purpose of preventing premature coagulation of the blood)

13 Only the crescentic bodies are capable of infecting and developing in the mosquito and not the active forms of the parasite as seen in the corpuscles during the attack

14 If after some weeks the crescentic body has not found its way to the mosquito s stomach it may die or it may retire from the general circulation to the liver or spleen, where it can remain without causing symptoms for a long period But any severe constitutional disturbance such as might be caused by the removal of the individual from a warm to a cold climate may result not only in these bodies reappearing in the circulation but in their having the power to multiply and produce a crop of active fever-causing parasites and what is known as a recurrent attack, even after the lapse of two or three years

15 As in the case of the relapse the recurrent attack has most of the features of the primary attack and anyone returning say to South Africa and suffering from a recurrent attack even in a district hitherto free from malaria and years after his return may become a danger to his friends or even the nucleus of an epidemic if the right kind of mosquito happens to be an inhabitant of the neighbourhood and if mosquito net precautions are not thorough

16 *The mosquito* —Only the female mosquito has the power of sucking blood the male subsisting upon the juice of plants fruit &c

17 Not all species of mosquitoes can convey malaria The majority of the common species are harmless (except those which transmit yellow fever elephantiasis &c)

18 The few species which are capable of conveying it belong to the class *Anophelinæ* all of which are fragile insects not easily seen, comparatively silent and whose bite leaves little irritation

19 It is therefore unwise to commit oneself to the remark so frequently heard that there are no mosquitoes in a particular place or camp without the opinion of an expert

20 All mosquitoes lay their eggs upon water and the larval and pupal stages of their life are spent in the water They wriggle to the surface periodically to breathe

21 When the pupa is ready to change into the mature insect it rises to the surface the pupa-case splits down the back the mosquito emerges and after an interval for its newly formed wings to harden it flies away

22. If a thin layer of kerosene oil be spread upon the surface of the water neither larvæ nor pupæ can get their breathing tubes to the surface and all die of suffocation a never failing and ever ready method of preventing mosquitoes hatching out of receptacles which cannot easily be emptied of water

23 Where there is no water there can be no mosquitoes

24 No other insect can convey malaria Where there is malaria there must be anopheline mosquitoes

25 It does not follow that because there are anopheline mosquitoes there must be malaria The insects though present may not have been infected and therefore harmless

26 One bite is sufficient to cause an attack and one infected mosquito may give malaria to several persons in one night

27 Those species of anopheline mosquitoes which convey malaria are not usually found away from human habitations or if found are not likely to be infected Consequently men on piquet duty or in bivouac or temporary camp although severely bitten by mosquitoes often run less risk of malaria than those in camps or hospitals on lines of communication where numbers of men who have suffered from malaria are congregated and where every anopheline mosquito is likely to be infected

28 *The mosquito net* —The segregation of the individual beneath an efficient net at night is by far the most important and effective means not only of guarding against a primary attack but of preventing infection being carried from the sick person to healthy persons

29 Owing to the development of crescentic carrier bodies after and not during the continuance of the fever the use of an efficient mosquito net is far more important to the welfare of the community after than before the attack.

30 One person or even a baby with crescentic bodies in his blood sleeping without a mosquito net or with one that is defective may be and often is the nucleus of an epidemic

31 Hence arises the danger of sleeping near a native village because in a malarial locality a large percentage of the youngest children have active parasites and crescentic bodies in their blood and yet play about without showing symptoms of fever

32 Adult natives on the other hand in a malarial locality are not usually a danger for having suffered severely in early childhood they have acquired a partial immunity and in consequence suffer little from malaria.

33 Strangers however from upland regions where there is no malaria not having suffered from the disease in childhood, have acquired no immunity and are soon likely to be infected on reaching a malarial district at a lower level

34 Indians rarely seem to acquire any immunity and are very susceptible to malaria. Their proximity is a danger to European.

N

---

[1] These notes amount to an amplified syllabus of lectures delivered in the field to troops in East Africa Major Christy s practice was to lecture for half an hour and to answer questions for another half hour He obtained very encouraging results

35 A mosquito net to be effective should be large enough to prevent the arms and knees being bitten through it and also to allow of its being tucked in all round

36 An efficient mosquito net properly used is a protection in tropical Africa against attacks from many harmful insects and animals besides mosquitoes For example: Flies which lay their eggs in the skin or in the nose at night, the maggots hatched from which sometimes cause irreparable injury or even death scorpions several species of dangerous centipedes poisonous ants beetles of many sorts which injure by biting ejecting poisons or by entering the ears ticks whose bite conveys serious fever snakes lizards rats &c and by means of its calico top from dust and dirt dropped from above in hut or tent or from heavy dew when sleeping in the open.

37 The lightest and smallest net which can be made serviceable under all circumstances whether in hospital clearing station camp or bivouac is one with calico top 5 feet 6 inches long by 2 feet broad and with sides 3 feet deep (2 feet of netting and 1 foot of calico tuck in) At each four top corners are double tapes, 8 inches long for fixing the net to its supports

38 The latest approved ordnance pattern is a rectangular net of the above dimensions To be effective it must be suspended by means of its corner tapes inside its supporting sticks otherwise it cannot be tucked in On no account should it be placed over its supports nor allowed to sag or hang loose

39 For military purposes the mosquito net should of course be khaki or any other less conspicuous colour than white but khaki netting being unobtainable it is advisable for each man for his own safety to dye his net with Condy's fluid coffee or other colouring agent

40 There are other methods of individual segregation than by the mosquito net The best of these is by the use of "Bamber oil" a mosquito lotion used extensively by coolies on the plantations in Ceylon &c

Its composition is as follows —

Citronella oil (not lemon grass oil) ..	1½ parts
Kerosene (paraffin) oil	1 part
Coconut oil	2 parts

To which is added carbolic acid 1 per cent Its efficacy lasts from four to six hours sufficient to give a night's sleep in comparative safety when a mosquito net is not available or cannot be used

41 *Quinine* —Quinine is the only drug in the world we know of which will kill the malaria parasite and consequently quinine is the only drug of any use as a prophylactic against malaria—that is for the prevention of primary attacks - and it is the only medicine which will cure the disease

42 Quinine being absorbed into the blood kills the parasite freshly injected by the mosquito but when after three or four hours these have entered the corpuscles quinine has less effect upon them

43 Quinine should therefore be taken early after any risk has been incurred but as the exact time of the risk can rarely be determined the best way to accomplish this is to take it frequently

44 A daily dose of grains 5 after the evening meal is for many reasons the wisest procedure

45 A grains 5 dose taken at 10 P M will kill any parasites which may have been injected by mosquitoes during the evening and will remain in the blood long enough to put out of action any that may be introduced up to 6 A M next morning The hours of daylight need not of course, be provided for

46 If quinine is taken only on Saturdays and Sundays a person may be bitten by infected mosquitoes on the Monday and the parasites injected may have so multiplied in the body by the time Saturday comes round again that an attack of fever is unavoidable

47 Quinine alone will not reduce the chances of infection more than perhaps 25 or 30 per cent but quinine plus the intelligent use of an efficient mosquito net should reduce those chances by at least 90 per cent.

48 Quinine is the only specific for malaria It cuts short the attack by killing the young parasites as each successive crop develops in the blood

49 If taken in sufficient quantities during the attack it will prevent the formation of the crescentic bodies, which once formed constitute the convalescing patient a danger to his fellows, and in spite of quinine may remain in the body for a long period

50 A slight attack is just as dangerous in this respect as a severe one and a person refusing to go sick "for a little fever" and neglecting to take quinine deserves to be severely dealt with

51 If continued after the attack in sufficient doses daily it will account for all the resting latent forms of the parasite in the spleen &c, prevent relapses and bring about a permanent cure but the mosquito net protection must be efficient and fresh attacks from bites of infected mosquitoes not allowed to supervene

52. A good method of quinine after treatment—that is, from the date of the subsidence of the fever—is as follows —

At least 20 grains daily for 2 weeks
15 , 2 ,
5 , 2 months

53 With the quinine may be combined if necessary, iron and arsenic tonics as ordered by the medical officer

54 Opinions regarding the after treatment by quinine frequently differ as to when and how the drug should be taken but the main point to realise is that the dosage should be daily for three months and the daily dose sufficiently large during the first month of the three If a relapse should occur the three months treatment must be commenced afresh.

55 Neglect of quinine after the attack will certainly result in a relapse which may mean the development of additional resting forms and crescentic bodies as well as the further decrease of the resisting power of the body tending to other relapses and general debility

56 The deafness and other slight effects of taking quinine are not permanent However unpleasant the effects may be they are infinitely preferable to the risk of permanent inefficiency or loss of life.

57 Although the taking of quinine has in some cases resulted in the passing of black water unaccompanied by any fever, quinine is certainly not the cause of blackwater fever

58 Although we may not know precisely what is the cause of this disease there is plenty of evidence to show that malaria is the initial factor To prevent malaria by the careful use of a net or to bring about a permanent cure by energetic after treatment with quinine, is the only way of avoiding risk of blackwater fever

In THE LANCET there have been published recently the notes of cases of malaria occurring in England, and in one district these cases have been quite numerous, so that notification has been enjoined There is no statement in the above notes, which were written originally for the troops in East Africa, which does not apply equally to any condition arising in the home country, but it should be remembered that atmospheric temperature is an important factor in the propagation of malaria In a temperate climate not only is the parasite in man retarded in its development in the blood, but its development in the mosquito is also delayed Moreover, the mosquito itself is disinclined to suck blood till the temperature rises to what in England is looked upon as tropical heat We are familiar with the reports in the lay press of the widely spread occurrence of mosquitoes whenever there is an unusually high summer temperature These reports are written in ignorance of the fact that the gnat is always with us, but only bites in what is regarded in this country as very hot weather A simple form of malaria was very common at one time in the eastern counties, and might become so again, though the severe malaria of the tropics is not likely to be prevalent.

NOTES ON THE

TREATMENT OF SUBTERTIAN CEREBRAL MALARIA WITH QUININE AND GALYL

BY A. W FALCONER, M D, CH B ABERD, M R C P LOND,
MAJOR, R A.M C (T)
AND
A. G ANDERSON,
CAPTAIN R.A M C

SALVARSAN and neosalvarsan have been used to a considerable extent during the last six or seven years in the treatment of malaria Most observers are agreed that these drugs, especially when associated with quinine, are of value in infections with the benign tertian and quartan parasites, but are of little value against infections with the *Plasmodium laverani* Although quinine alone may justly be termed a specific in the treatment of most types of malaria the death rate from malignant subtertian malaria is yet sufficiently high to stimulate further effort to find an even more efficient therapy

Cases Treated with Quinine and Galyl Combined

The following six cases were treated with a combination of quinine and galyl

CASE 1 —Private C, aged 31 was admitted to base hospital on Sept 22nd 1916 He had reported sick on Sept 18th complaining of headache vomiting and "the shivers" He stated that for the previous three months he had been having attacks of shivering and sweating at irregular intervals On admission to hospital his general condition was good his temperature was normal and his spleen extended half an inch below the costal margin. He was treated with 20 grains of quinine sulphate three times a day by the mouth He felt quite well and his temperature remained normal until the morning of Sept 25th. On that date his temperature rose to 100° F and remained up all day

On the morning of the 26th the temperature had fallen to normal, but rose again in the evening to 101° and the patient felt sick and vomited An injection of 20 grains of quinine bihydrochloride was administered intramuscularly

On the morning of the 27th another injection of 20 grains of quinine was given intramuscularly His temperature was normal and did not rise above normal throughout the day At noon the patient refused his food, and looked strange at 3 P M. he was found to have complete paralysis of the muscles of both sides of the tongue of the pterygoids, and of the masseters There also appeared to be some weakness of the external recti There was no paralysis of the limbs or alteration of the superficial or deep reflexes The patient was quite conscious and could carry out directions as to the movements of his limbs the fundi oculorum were normal. A blood film showed the presence of numerous subtertian rings and crescents He was given an intravenous injection of 0·8 gm of quinine bihydrochloride. At 8 P M the patient's condition was unchanged except that he now appeared to have some difficulty in understanding what was said to him. There was a definite internal strabismus of the left eye a further 0 8 gm of quinine was administered intravenously

On the morning of the 28th the condition of the patient was much improved. He could open his mouth protrude his tongue and articulate slowly He had some difficulty in swallowing as fluids tended to regurgitate through the nose There was still defective movement of both eyes outwards In the afternoon his temperature rose to 100° On this date he was given two intravenous injections of quinine bihydrochloride, 0 8 gm each.

On the morning of the 29th his condition was much worse There was complete paralysis of the tongue the palate and the muscles of mastication There was also complete ophthalmoplegia, and it was doubtful whether the patient understood what was said to him. At 9 A.M he received a further 0 8 gm of quinine bihydrochloride intravenously At 11 A.M as there was no improvement in his condition he was given 0·3 gm. of galyl intravenously At 3 P.M the patient was much improved. He could then protrude his tongue move his jaw talk slowly but quite intelligently swallow slowly and move his eyes At 9 P.M. he was given a further 0·8 gm of quinine intravenously

On the 30th the patient's condition had continued to improve There was still some dysarthria but he was able to swallow without difficulty He was put on 20 grains of quinine sulphate three times a day by mouth The improvement steadily continued but on Oct 1st, as the temperature still rose to 100° he was given 0·2 gm of galyl intravenously The temperature fell that night and remained subnormal during the rest of his stay in hospital He showed no further symptoms and was transferred to hospital ship on Oct. 16th when there was no evidence of organic nervous disease and no malarial parasites could be found in the blood.

CASE 2.—Sapper R., aged 33 was admitted to base hospital on Oct 4th 1916 On admission the patient's general condition was bad and the temperature was 103° F He showed no evidence of any local lesion of the nervous system A blood film showed the presence of numerous subtertian malarial parasites He was given 0 8 gm of quinine bihydrochloride intravenously On the morning of the 5th his temperature was subnormal but his general condition was very poor He was again given 0·8 gm. of quinine intravenously, and at 2 P M 20 grains of quinine sulphate by the mouth. In the afternoon the patient developed marked dysarthria and difficulty in swallowing The speech was quite unintelligible. The movements of the tongue and palate were present but much impaired. The patient's mental condition was not affected and there was no paralysis of the limbs or alteration in the superficial or deep reflexes. At 6 P.M he received 0 4 gm. of galyl intravenously On the 6th the patient's general condition was much improved, and beyond slight dysarthria, which rapidly passed off he showed no evidence of local disease of the nervous system. He was then treated with quinine intramuscularly and later by the mouth, and rapidly became convalescent He was transferred to hospital ship on Oct 21st without any evidence of organic nervous disease

CASE 3.—Private B aged 48, was admitted to base hospital on the night of Oct 7th complaining of headache and general weakness. On admission his temperature was 103° F., but fell to 99° on the morning of Oct. 8th. His general condition was fair and his spleen extended about one inch below the costal margin He was treated with 20 grains of quinine sulphate three times a day by the mouth. He took his dinner at noon on the 8th without discomfort, but at 4 P.M. it was found that he was unable to swallow his tea, and he rapidly became unconscious. A blood film showed the presence of numerous subtertian rings and crescents. When seen at 5 P.M he was lying in a semi-conscious condition and did not pay any attention to what was said to him. The conjunctival reflex was present and the superficial and deep reflexes were normal The unconsciousness rapidly deepened and he could not be roused by any stimulation He received 0 8 gm of quinine bihydrochloride at 5 P.M 7 P.M and 10 P M At 11 P M his condition was unchanged except that his pulse was falling He then received 0 4 gm of galyl intravenously When seen at 6 A M next morning he was quite conscious able to answer questions slowly and intelligently and swallow His temperature was subnormal and remained so for the remainder of his stay in hospital A blood film showed the presence of scanty subtertian crescents up to Oct 15th but he showed no further symptoms and was transferred to hospital ship on the 22nd

CASE 4.—Private C aged 25 was admitted to the base hospital on Oct 10th On admission the patient's general condition was poor his temperature was 99° F., and his spleen extended about one inch below the costal margin A blood film showed the presence of rings and crescents He tended to be drowsy but answered questions quite intelligently and had no complaints He was given 0·8 gm. of quinine bihydrochloride intravenously On the morning of the 11th the patient's general condition was worse, he was more drowsy and answered questions with difficulty The pulse was 120 per minute and feeble He received 15 grains of quinine bihydrochloride intramuscularly At 3 30 P.M his condition suddenly became much worse his breathing became stertorous and his pulse imperceptible he lay moaning incessantly and rolling his head from side to side. There was no paralysis and his superficial and deep reflexes were normal His temperature was subnormal. At 4 P M he became violent and lay on his left side in the typical attitude of cerebral irritation He violently resisted any interference with this position. He received 0 4 gm of galyl intravenously At 9 P.M his condition had definitely improved He had slept for two hours and his pulse was better At 1 A M on the 12th he again became rather excited and was given 1/150 grain of hyoscine After this he slept and when he awoke was rational though weak From this date he rapidly and steadily improved and on the 22nd was transferred to hospital ship without presenting any further local symptoms

CASE 5.—Private L. aged 20 was admitted to the base hospital on Oct 15th 1916 with a diagnosis of malaria. On admission his temperature was normal, and he presented no local symptoms His spleen extended half an inch below the costal margin He had never suffered from fits nor had any of his family done so On Oct 16th whilst in the latrine he suddenly developed an epileptiform fit After having been brought back to the ward he was in a very confused condition and paid no attention to any questions but constantly attempted to get out of bed The blood film did not show any malarial parasites His temperature had risen to 101 [illegible]° F During the 16th he continued to have epileptiform fits and in the 24 hours had some 12 in all. The clonic convulsions were general and did not appear to begin constantly in any particular part but they were always associated with marked deviation of the head and eyes to the left Between the fits he was either extremely drowsy or violently delirious At 2 P M he received 0·8 gm of quinine bihydrochloride intravenously and at 6 P.M. 20 grains intramuscularly

On the morning of the 17th his temperature was 101° and his pulse-rate 80 per minute He was very drowsy and had passed no urine He received 20 grains of quinine intramuscularly At 9 P.M he developed another fit, and it was noted that the left plantar reflex was extensor the right plantar reflex was flexor He was given 0 4 gm of galyl intravenously and a lumbar puncture was performed The cerebro-spinal fluid appeared to be under increased pressure and two test tubefuls of clear fluid were drawn off The cerebro-spinal fluid showed no increase in cellular elements At 8 P.M as he had passed no urine for 38 hours a catheter was passed and less than an ounce of urine was obtained It did not contain any albumin sugar or casts

On the morning of the 18th the temperature was normal and the patient's general condition improved He answered questions quite readily and was taking his nourishment well The left plantar reflex was still extensor and there were marked nystagmoid jerkings of the eyes on lateral movement to either side. The left leg was distinctly weaker than the right but was capable of performing all movements with a fair amount of force and there did not appear to be any ataxia of the limbs Urine was being passed quite freely He was given two doses of 20 grains of quinine intramuscularly on this date.

From this date onwards he was treated with quinine at first intramuscularly and later on by the mouth. Convalescence was uninterrupted The weakness of the left leg rapidly improved, but the plantar reflex remained extensor for four weeks. The nystagmoid jerkings of the eyes varied somewhat from time to time but were still definitely present six weeks after the patient's admission to hospital When able to get up he showed a pronounced reeling gait and unless supported he tended to fall to the left He stated that he felt as if his head were being pulled to the left When made to walk holding his head down to his right shoulder with his right hand the tendency to reel to the left was diminished but was still present. There was no Rombergism and no ataxia The optic discs were normal He had no further fits after the 18th and was transferred to hospital ship in February 1917

CASE 6.—Dr S aged 22, was admitted to hospital on Sept. 29th 1916. He reported sick on the 21st, complaining of pain in the head and back, and diarrhoea On admission to hospital his general condition was fair his temperature 103° F his pulse 120 per minute and his spleen two inches below the costal margin He was put on 40 grains of quinine sulphate by the mouth per day On Oct. 2nd as the temperature was still raised he was given 20 grains of quinine bihydrochloride intramuscularly in addition On the 4th his temperature did not rise above 99° and he appeared somewhat better On the 5th the temperature again rose to 101 4° and he complained of some pain in the neck and a little difficulty in swallowing No definite affection of the cranial nerves could be made out but the right plantar reflex was definitely extensor He was again put on quinine intramuscularly On the 6th the temperature again rose he still complained of pain in the neck and the right plantar reflex was still extensor The respirations had increased in frequency and there was some dullness at the base of the right lung posteriorly He was given two doses of 0·8 gm. of quinine intravenously On the 7th as there was no improvement, he was given 0·4 gm of galyl intravenously He died on the morning of the 8th

Post mortem the whole of the upper and lower lobes of the right lung were solid in a condition of grey hepatisation There was a considerable accumulation of cerebro-spinal fluid below the tentorium and some œdema of the pia arachnoid over the pons and medulla. The brain was hardened in formalin and then sectioned but it did not show any macroscopic change

Effects of Galyl Alone

In these six cases galyl was used in association with large doses of quinine. So far we have been able to make only a limited number of observations of the effect of galyl alone on the subtertian parasites in the peripheral blood stream, but that galyl alone can cause the disappearance of the ring forms of parasite from the peripheral blood stream is shown by the two following cases

CASE 7.—Sister S aged 28, was admitted to hospital on Nov 12th 1916 with pyrexia. Numerous subtertian rings were present in the blood The patient was put on 20 grains of quinine sulphate three times a day by the mouth This produced constant vomiting headache and very troublesome tinnitus aurium The parasites persisted in the blood stream and the pyrexia continued On Nov 14th she was put on intramuscular injections of quinine bihydrochloride, 20 grains twice a day The intramuscular injections were continued for four days but the patient was extremely intolerant of quinine and complained of violent headache and tinnitus aurium with occasional vomiting The temperature was swinging between 97° and 101° F Subtertian rings were constantly present in considerable numbers in the blood She was again put on quinine by the mouth but on account of vomiting it was impossible to get her to take it regularly

An intermittent pyrexia continued up to Nov 27th and during this period subtertian rings were constantly present in the blood On Nov 27th she received 0·2 gm of galyl intravenously Her general condition definitely improved but the blood still showed subtertian rings although in diminished numbers up to Dec 6th when she had a second dose of 0 4 gm of galyl From this date onwards there was a marked general improvement in her condition although she still continued to show an irregular pyrexia rising to 100° at night her blood was examined every few days for malarial parasites until her discharge some two months later but these were not again found On Dec. 10th typhoid bacilli were isolated from the stools and on Jan 2nd 1917 she developed a periostitis of the right humerus

CASE 8.—Private B aged 26, elsewhere reported in detail was admitted to hospital on the night of Oct 4th 1916 On Oct 5th his temperature rose to 102° F., his general condition was poor his sclerotics icteric, and he presented gangrene of the toes of both feet. A blood film showed the presence of rings and crescents, anisocytosis poikilocytosis, and polychromatophilia As it was considered possible that a vascular spasm aggravated by quinine might play a part in the condition of the feet he was not put on quinine but given 0·3 gm of galyl intravenously His temperature fell that night and remained subnormal throughout the rest of his stay in hospital His general condition rapidly improved and a blood film taken on the 10th was reported negative to malarial parasites Two other blood films taken later were also reported negative Before his discharge to hospital ship he was put on 10 grains of quinine sulphate twice a day by the mouth.

Persistence of Crescents under Combined Treatment

In this case it will be noted that the crescents also disappeared rapidly from the blood, but in most of our cases of combined quinine and galyl treatment the crescents have been much more persistent, as in the following case

CASE 9 —*Private K* aged 23 was admitted to hospital on Dec 23rd, 1916 with a diagnosis of bronchitis The patient had been in hospital in May 1916 with a diagnosis of P U O and in October with malaria He had not felt well since leaving hospital in October and he stated that he had had frequent shivering fits since then. During September and October he had taken 30 grains quinine by the mouth per day but had only been taking it irregularly in November and December

On admission the patient s general condition was poor His temperature was 102° F and rose to 103° next day, to fall to normal on the 25th His blood showed numerous subtertian crescents and rings From Dec 24th to 27th the number of crescents met with in counting 200 leucocytes was practically constant, the figures being 100 crescents to 200 leucocytes On the 27th he was given 0 4 gm of galyl intravenously On the 29th the crescents had fallen to 50 on the 30th to 36 for every 200 leucocytes On the 30th he again received 0 4 gm of galyl On Dec. 2nd the crescents had fallen to 24 in 200 leucocytes on the 3rd to 14 and on the 4th to 7 crescents for every 200 leucocytes

On the evening of Jan 11th the patient developed catarrhal symptoms with a temperature of 101° but without any rigor A similar condition was at that time present in the ward and was almost certainly not malarial The temperature was normal on the 6th and on the 6th and 7th the crescents numbered respectively 11 and 10 to 200 leucocytes He received another 0 4 gm of galyl on the 7th On the 8th his temperature rose again and he had a malarial attack Rings were found in the blood on the 9th His temperature became normal again on the 11th and his blood showed no rings but 23 crescents to 200 leucocytes He was put on 40 grains of quinine bihydrochloride intramuscularly once a day and 20 grains of quinine sulphate twice a day by the mouth On the 13th 14th and 15th his blood showed 8 7 and 8 crescents respectively to 200 leucocytes On the 23rd and 24th 1 crescent to 200 leucocytes was found and on the 25th and 26th no crescents could be found in counting 300 leucocytes

On Feb 1st 1 crescent was found in counting 200 leucocytes on the 2nd, 3 crescents to 200 leucocytes On the 4th and 6th no crescents were found in counting 400 and 300 leucocytes respectively His general condition was now excellent and he was transferred to hospital ship on Feb 7th

Remarks

With regard to the value of combining galyl with quinine in serious cases of malaria our experience is yet too limited to permit of any dogmatic statements as to its efficacy It will be noted that in the first six cases reported here all were seriously ill with definite subtertian cerebral malaria All the cases recovered, with the exception of one who died of a complicating croupous pneumonia All had received quinine, several of them large doses by the mouth, intramuscularly, and intravenously, without clinical improvement In all of them, with the exception of the fatal case, the clinical improvement after the administration of galyl was striking and immediate In none of the cases did the injection produce any unpleasant results, although several of the cases appeared almost moribund before the injection

In Case 8, in which it was considered inadvisable to give quinine, galyl alone caused the disappearance of the parasite from the peripheral blood and produced a striking improvement in the condition of the patient

In Case 7 the patient took quinine in any form with great difficulty, and although she had taken a considerable amount of quinine by the mouth and intramuscularly ring forms of the subtertian parasite were constantly present in the blood After the first half dose of galyl there was a notable clinical improvement, but the parasite could still be demonstrated in the blood After the second dose the parasites at once disappeared from the blood The typhoid ran a protracted course, and she developed a periostitis of the left humerus, but in spite of repeated examinations parasites were not again demonstrated in the blood during the rest of her stay in hospital

In Case 9 subtertian crescents were present in large numbers Under treatment by galyl alone they diminished from 100 per 200 leucocytes to 7 or 8 The patient's general condition very greatly improved, but he still developed a malarial attack with the presence of rings in the blood These rings disappeared under treatment by intramuscular quinine and the crescents continued to diminish and were absent on Feb 7th, when he was transferred to hospital ship

We consider that we are justified in concluding 1 That the treatment in itself is free from danger 2 That in subtertian malaria which is resisting adequate quinine treatment, or where the condition is sufficiently alarming, the results of the combined galyl and quinine treatment have been encouraging enough to justify a further trial It must be thoroughly understood, however, that the addition of galyl in no way diminishes the necessity for quinine 3 That in cases where, on account of idiosyncrasy, quinine is impossible a valuable substitute may be found in galyl

We take this opportunity of thanking Colonel Purves Stewart, C B , A M S , consulting physician to the Salonika Force, for his valuable assistance and advice which were always at our disposal To Lieutenant-Colonel P Mitchell R A M C (T F), we are also indebted for permission to use the hospital records, and to Captain R Richards R A M C (T F), for the hæmatological and post-mortem reports

SURGERY NEXT DOOR TO THE FRONT

BY T B LAYTON, M S LOND , F R C S ENG ,

LIEUTENANT COLONEL, R.A.M C (T)

IN his first Lettsomian lecture[1] Colonel Cuthbert Wallace sums up war surgery as being "in a great degree a matter of when and where to operate, and how best to move the wounded man to the place where he will win back to health "

The decision as to when and where to operate is not merely one of the operation, it is also a matter of how and where to nurse the patient afterwards No nurse, male or female, can attend properly to a patient in a stretcher on the ground or at the most raised up on a trestle The first of the above questions resolves itself into the fact that no operations should be done in any unit that has to remain mobile so long as the patient can be got back in a reasonable time to an immobile unit which has all the facilities of the modern operating theatre and of modern nursing

The surgical work in a field ambulance therefore must be directed towards the second of Colonel Wallace s principles, "how best to move the wounded man " It is a matter of great importance that so high an authority should have publicly enunciated this as one of the two great principles of war surgery There was a great tendency in the earlier days of the war for people to think that anyone with a knowledge of surgery was wasted when he was working in a field ambulance or as medical officer in charge of a battalion, and one was frequently told of some clever youth who had done nothing during many months of active service which could not have been done equally well by a well trained orderly or a third year medical student It is the purpose of the first part of this paper to discuss from the surgical standpoint certain factors connected with the movement of patients which have come to the writer s notice

Factors connected with the Movement of Patients

We must first have some clear idea as to what we mean by the ' reasonable time' within which we must get the patient back to the immobile unit—that is, to the casualty clearing station organised not on the lines laid down in the War Establishments and the Mobilisation Store Tables of 1914, but on the lines in which they may be seen in the stationary warfare of to day

It has long been recognised that for the successful treatment of an abdominal wound the number of hours which have elapsed between the time that the man was hit and the time at which he arrives at the operating unit is inversely proportional to his chances of recovery, and it has been the aim and object of all to get this class of case into the operating unit with the utmost rapidity

But as the principles of wound treatment have developed it has become clear that the same rapidity should be aimed at in all cases The latest notes on Carrel s treatment say "Treatment should be begun, if possible, within 12 hours of receipt of wound, and not later than 24 hours if the maximum success is to be obtained " Our ideal should be then, to get every case back to the C C S at the quickest possible moment, in the same way as we now try to do with abdominal cases

The actual number of hours is however, not the only factor to be considered Some cases are suffering so severely from shock that to get them down to the C C S in the shortest possible time results in their arriving moribund and it is necessary in some cases to delay the journey several hours or to use some means of transport other than the most rapid if it is likely to lead to less jolting on the journey

---

[1] THE LANCET 1917 i 561

Our subject then falls under two heads —

1. Under *collection*[2] *and evacuation*[2] (*a*) to consider whether we can get every wounded man into the C C S in the shortest possible time, which in one part of a line may be four hours or under and in another 12 hours or over (*b*) If we cannot evacuate to the C C S all cases within this time, to decide what steps can be taken to get down selected cases and what are the cases to which this preferential treatment should be given

2 Under *prevention of shock and collapse* to consider what can be done (*a*) by the general principles known to civil surgery, (*b*) by the application or improvisation of special appliances for certain types of cases, (*c*) by the selection of means of transport in serious cases

Any steps that we conclude shall be taken should be worked out during the relative quiet of trench warfare We shall always be met by the criticism that you cannot do such things during an engagement To this there are two replies That you may be unable to do all, but that if you have practised them in trench warfare you will certainly be able to do some, whereas if you have never thought of them you will equally certainly do none And that even if you could take none of these steps during an engagement you have still done a useful bit of work by applying them to the casualties of routine trench war

Collection and Evacuation

1 (*a*) The time that a patient takes to arrive at the C C S is partly taken up by his being carried from one post or station to another and partly by the time which he remains at such a station or post. From the time that he is wounded to the time that he is ready to leave the regimental aid post (R A P) he is in the charge of the regimental medical officer, and any speeding up of the time during this stage must be the concern of the medical officer and his commanding officer From the time that he is ready to leave the R A.P to the time when he is ready to leave the main dressing station (M D S) he is under the charge of the officer commanding the field ambulance, and during the stage from the M D S to the C C S he is still under the officer commanding the field ambulance when the deputy director of medical services corps, has decided that this stage of evacuation should be done by field ambulance transport This is usually the case in normal trench warfare where the field ambulance transport is not pressed to get its proper work done This is to collect the cases from the advance dressing station (A D S) to the M D S

It is clear, then that any speeding up in the collection and evacuation of cases can either be done by the transport between these various points moving at a greater rate or by the time during which they are kept at the various points being shortened Now the time that any form of transport takes to move over a given road, path, or track cannot vary much, and as will be urged later, it is possible that such rapid movement does more harm by causing increased shock than it does good by getting the patient along more quickly

If any time then is to be saved it must be done by shortening the periods during which the patient remains in the various stations Part of this time is of course taken up in examining, dressing, and feeding the patient but for the rest of it he remains in the ward resting till it is his turn to go on to the next stage If transport could be ready so that every patient were sent on to the next station the moment he was dressed and fed and the personnel at the next station could be informed of the exact time he was arriving then every case would arrive at the C C S in the minimal period of time

This on the face of it is impossible, because it would mean that if cases came into the A.D S in a bunch every one would have to be dressed and fed simultaneously, whereas if they arrived one by one a fresh vehicle or other means of transport would have to be called out for every minor case with the result that a gross waste of transport would occur

The matter is made more difficult by the facts that in many places collection from the A.D S to the M D S can only occur by transport by night that the distance is too great for hand carriage to be possible for every single case, that hand carriage even from the R A P to the A D S may be impossible by day Further, it may be inadvisable to send cases on from the M D S to C C S at certain times of the day, either because it is too hot by daytime or because it is too cold by night

We see, then, that our ideal that every wounded man should arrive at the C C S in the minimal time is one to which we cannot attain, and all we can do is to make the average time for all wounded cases as short as possible by an efficient organisation and administration

Selection of Cases

1 (*b*) But if we cannot get every case down to the C C S in the minimal time we can do much to get down within this time certain selected cases Where early operation may save the man s life or limb we are warranted in taking greater risks We should go over roads and paths under observation from the enemy by daylight We must use transport for a single case more extravagantly than would be justified if it were not for its urgency

What then are the cases for which these steps should be taken? That they should be taken for all cases where the abdominal cavity has been opened and the man is fit to move has long been recognised *With the development of* Carrel's method of disinfecting gunshot wounds" we should like to take these steps in every case of gunshot wound, however slight In the smaller flesh wounds, however, we can hardly claim that the man s life and limb is so endangered by deferring the treatment for longer than 12 hours that we should risk other men s lives to get them down within that time. In wounds of the bones and joints, however we can claim this In all such cases steps should be taken to get them away from the line to the C C S in the minimal time even at great inconvenience to the organisation of the stations on the way and at considerable risk to the R A.M C and A.S C men, whose duty it is to convey them What are the steps which can be taken to secure this? These have already been indicated That roads and paths under observation over which traffic is not normally allowed by day should be open to field ambulance transport for these selected cases, and that this transport should always be at the right spot at the right moment Permission to use such roads and paths can be obtained from the general officer commanding the sector The reason for not normally allowing traffic along such roads is not merely owing to the danger to the person passing along it, this, indeed, is often negligible It is much more owing to the danger to the men who live near the road Frequent movement along a road or path tends to draw fire not necessarily while the movement is going on. The person who bears the brunt is not the man living in the safety of the back area who spends an hour or two once a week getting somewhere near the zone of fire, but the fellow who has to live in that zone of fire day and night, and is lucky to get into the safety of the back area once a month to get a bath It is therefore most important when permission is given to take transport along such a road or path that this permission should not be abused, and that it should be used only for the purposes for which it was given

To have the right transport ready at the right spot and at the right moment is no easy matter Transport may be kept for weeks at one spot doing nothing and then be withdrawn for some other purpose, only to get a small run of cases at that very spot as soon as it is withdrawn The most important thing is to have good communication between the M D S and A D S, and again between this and the R.A Ps ahead In this way the medical officer of the battalion can notify the officer in charge of the A D S that a case is coming along and if the necessary transport is not there it can be got up to the A D S by the time the patient has arrived from the R A.P For this reason it would be well if every M D S and A.D S were on the telephone

But for getting patients down to the C C S in the minimal time it is invaluable and should save many lives An example of what can be done in this way may be given A certain field ambulance collecting from a two-brigade front had an advanced dressing station at a cross roads, up to which the cars went by night but to which permission was given for them to go up by day for the purpose of evacuating abdominal cases only It had been the custom for the case to be brought to the A D S where the medical officer examined it. He then had to send a runner along the trenches to the nearest signal office to send a message to the M D S through the rear brigade headquarters The brigade signal officer found a spare receiver and fitted it in to the A D S, and the code word "GUTS" was used and known at the six signal offices of the battalions in the line, at the two signal offices at advanced brigade headquarters, and at the two signal offices at rear brigade headquarters When the battalion medical officer had a case of a wound in the abdomen he sent this code word both to the A.D S and to the rear brigade headquarters, from the latter of which it was sent by runner to the M D S An ambulance car was then sent up at once to the A D S, where the medical officer in charge was ready expecting the case He looked to see if the case were fit to be sent on and put it straight in the car, which took it at once to the C C S In this way the minimal period was reduced from over six hours to four hours, and far more cases got down in the minimal time than had done so before because everyone was waiting expecting the case as it came along This was done without any acceleration of the rate at which the patient travelled over any given part of the trenches or the road.

---

[2] These are technical terms Collection" includes the various stages between the place where the man was hit and the main dressing station of the field ambulance. Evacuation" includes those stages from the main dressing station to the general hospital at the base of which the first only to the C C S is under discussion in this paper Vide Field Service Regulations vol. ii and R A M C Training

Prevention of Shock and Collapse

2 (*a*) This resolves itself chiefly into getting the patients warm All are agreed on this point Before coming abroad the writer had thought he would do much with saline infusion, and brought on six sets of Lane's infusion bag apparatus They have been of great use, but their scope has not been as great as he had hoped There is always a doubt in an abdominal or chest case whether the bleeding has stopped, always a fear in a deep wound of the thigh that it may come on again before the case gets to the C C S In some cases infusion is necessary, even though the bleeding may not have stopped, but in these intracellular infusion is of no use and intravenous is very hard under the circumstances When it is done it must never be done instead of getting the patient warm, but only as an accessory to this When the boots are taken off a man but slightly wounded it is most striking how cold the feet are even on a warm day Hot-water bottles in large numbers are the great stand by This means hot water, and the field ambulance equipment would be very short of utensils in which to heat water if one stuck rigidly to the Mobilisation Store Table. It is the old question of mobility and transport, but everyone feels that a field cooker should be added to the field ambulance on a wheeled transport establishment, and some Soyer's stoves are most valuable under any circumstances Numerous blankets properly tucked in around the patient are the next factor, and this is followed by the hoods and stockings and socks that one can get from the Red Cross

2 (*b*) On the above all are agreed, but what is less generally recognised is that the earlier a limb is immobilised the better will the case be in every way at all stages Shock is enormously diminished by it, and the patient thus stands a better chance of his life Short of this, he is more likely to get severe suppuration when the shock has been great No case of a fracture of the long bone should pass the A.D S without being so treated If it has not been done by the medical officer in charge of the battalion a case of fracture of the femur should here be put up in a Thomas's splint, a fracture of the leg in a back splint with foot-piece and two side splints, of the forearm in an internal angular, and of the humerus either by binding the arm to the side or by a Jones's arm splint

But it is not only wounds involving the bone that should be put up in splints All extensive wounds of the muscles of the limbs should also be so treated at the advanced dressing station and, above all, wounds involving the joints It is not always possible, nay it is generally impossible, to tell at this stage whether the joint is involved, therefore every wound which is near a joint should be treated as though it involved the joint This is especially the case with the knee, where wounds which at first sight do not appear to be anywhere near the joint prove on arrival at the base to have involved it A wound of the knee-joint travels best in a Thomas's splint, and such should be put on at the A.D S If a back splint is applied to any lower limb it must extend from the fold of the buttock to the tendo Achillis Anything shorter than this is useless

But it is not only by the more thorough application of splints that shock can be prevented Every case of a wound involving the abdomen or chest should be conveyed in the semi sitting position with the knees bent A chair can be made attached to the two poles of a stretcher and the relief to the patient when he is put into this is so great that he will fall asleep without morphia, where beforehand he has been groaning with pain.

2 (*c*) The selection of the means of transport is often an important factor, and we must here go back to a point already raised—that the rapidity with which a patient arrives at the C C S does not depend so much upon the rate at which he passes over the ground as the time he is kept waiting at the R A P and dressing stations On the other hand, upon the smoothness with which the transport moves depends very much the degree of shock to which the patient will be subjected In other words, a motor ambulance car is not the best method of carrying a seriously wounded patient it is the worst The next in order of badness is the horse ambulance wagon The best way to move a seriously wounded patient is on a litter or a travois The writer prefers the litter because he has not yet seen any improvisation which enables a patient to be carried in the semi recumbent position in a travois, and with a long distance—say ten miles—the work is more than a mule can do to drag the travois with patient all the way For a short distance a long springy travois is possibly better for a case of fracture The wheeled ambulance-stretcher carriages when drawn by an animal are also good, but a patient who has been in both prefers the litter

In the writer's opinion one litter per section should be included in the establishment of a field ambulance with a wagon transport for the purpose of collection and evacuation of serious cases, and not limited to a field ambulance on a pack establishment merely for hill warfare He firmly believes that the time which would be lost in conveying a seriously wounded case from an A.D S to a C C S would be more than compensated for by the improved condition in which the patient would arrive.

Difficulties in Diagnosis and Treatment

The writer would add a third difference between civil and war surgery to the two enunciated by Colonel Wallace—viz, that the patient is under the care of the corps and not under any individual R A.M C officer This depends upon the fact that cases are passed so quickly from one unit to another that they are never long under the medical care of one man until they arrive at the C C S, and usually until they arrive at the general hospital The difficulty in making a diagnosis and in determining a line of treatment is increased and there is a possibility that the line of treatment adopted by one medical officer may be changed by the next Very likely the second treatment might have been the better had it been adopted from the first, but generally it is worse to change from one to another than to carry through to its conclusion an inferior line of treatment. It is well, therefore, to consider what steps may be taken to lessen this difficulty under which we work.

1 The most important thing is to standardise lines of treatment which have proved useful, and to insist that medical officers in the forward area should begin these and those on the lines of communication and at the base should carry them on when they have been begun This may appear to interfere with the right of each medical officer to treat his patient in the way which he himself thinks best but is necessary under the circumstances The principle has already been adopted in the routine administration of anti-tetanic serum, and might well be extended to definite rules as to the way in which certain cases of fracture should be splinted and classes of cases should be carried, kept, or hurried on to the next stage It will then rest with each medical officer to decide in any individual case whether he should take the responsibility of diverging from the line of treatment laid down

2 By instituting classes of instruction for medical officers from the base in the forward area where they could learn the difficulties under which the work is there done and at the base for medical officers in the forward area so that they could appreciate the importance of beginning some approved line of treatment at the earliest possible moment Schools of instruction have given excellent results in other branches of the service Medical officers with the field units have not had opportunities of learning methods of treatment which have been developed since the beginning of the war except by utilising brief periods of leave at the base when they have

had there some friend who has been able to show them around Medical officers at the base, especially the surgical specialists at the C O Ss and hospitals, would get a wider view of war surgery if they had the chance of going around the forward area on one or two nights and learning the conditions under which cases are collected from the firing-line

3 To consider as serious all cases which may possibly involve some important organ An accurate diagnosis can seldom be made by a medical officer who only sees the case for a short period Thus, many wounds of the buttock ultimately prove to have penetrated the pelvic cavity, and it is well to have a rule that every wound of the buttock other than a superficial through and through injury should be classed as an abdominal case, again, the early immobilisation of a wounded knee joint is so important that every case with a wound anywhere near the joint should be put up in a Thomas's splint at the earliest possible moment In each of these classes nine cases might be sent down with injuries that subsequently prove to be slight, but in the tenth the surgeon at the C C S has been given a chance to save the life or limb which he could not otherwise have had

4 Careful and accurate notes on the back of the Field Medical Card There is often a tendency to remove a dressing at the A.D S which has been put on at the R A.P or to re dress at the M D S a case that has already been efficiently dealt with at the A D S These repeated dressings lead to an increase of shock, and yet if there are no notes on the back of the card the medical officer at each stage is almost bound to look at the wound in order to decide what should be done An entry by the medical officer who first sees the patient of the time at which the wound was received is a great help, as is also an entry of the pulse-rate at each stage of the journey

5 To have some broad rules laid down as to the *administration of morphia* This decision is a most difficult one The medical officer at the R A.P is tempted to give a large dose because he feels that some heroic step must be taken to relieve the man of his pain over the next stage of his journey The patient then arrives at the M D S or C C S in a delirious state so that it is impossible to determine whether he is suffering from an excess of morphia or whether he is in a most critical condition as the result of his wound, and the decision as to the next step is a leap in the dark Doses of half a grain nearly always lead to these difficulties Instead of being comfortably under the drug the patient is restless and has lost all control over himself Every attempt to examine him, to dress him, or to move him into a more comfortable position is frustrated by the man himself It is said that smaller doses given at a R.A.P have no effect in relieving a severely wounded man Much can be done however, by paying particular care to move him in the most comfortable position If this is impossible it is better for the patient to undergo that pain until he arrives at the A.D S where he can be more efficiently splinted and where he can be put into a position which will automatically relieve him In the writer's opinion it is unwise to give more than one sixth of a grain, which can be repeated at the A.D S and M D S if necessary

Indications for Operation in Field Ambulance

Should any operations at all be done in the field ambulance? It must be admitted that the indications are but few

1 Abdominal cases which are too bad to be sent on to the C C S, but in which operation gives some slight hope of recovery These cases are extremely rare They are cases in which there is reason to believe that hæmorrhage is continuing but if the man is too bad to be sent on he is almost certain to be too bad for an *operation* and there is always the chance that the bleeding has stopped when it would be better to leave the man for several hours and to send him gently on after he has *picked up a bit.*

2 Cases needing immediate amputation These, again are very rare and are practically limited to those in which the limb is hanging by a piece of skin or a tendon which merely has to be snipped through Such can hardly be called an amputation, and if anything more *is needed the* man can either be sent on or is too bad for anything to be done

3 Cases of bleeding from a single large vessel. These seldom find their way into the M D S, as they are dead before arrival If a case is wounded close by a dressing station it may be possible for the medical officer to ligature the vessel with or without an anæsthetic being given

4 Cases of bleeding from more than one small vessel in a large muscular wound When a case arrives where the dressings have come through with the blood perhaps dripping on to the ground, where the pulse is rising, and the application of a fresh dressing does not promise to stop the bleeding, it is necessary to operate in order to pick up the bleeding points In such a case probably the best thing to do is to excise the wound and to insert the tubes necessary for Carrel's treatment The number of such cases is not great

I have not yet seen a case of head injury in which an operation in a field ambulance came within the bounds of discussion Supposing a field ambulance were in such a position that no cases could be got back to a C C S within 36 hours, and this delay was due to the distance of the M D S from the C C S and not to the time spent in collection of wounded, the M D S of the field ambulance would then take the place of the C C S as the operating unit, and the indications for operation would be increased

Illustrative Cases

The following cases, which have passed through the field ambulance under the command of the writer during the last three months, illustrate most of the points which have been considered in this paper In the area where we were working the A D S was some 2000 to 3000 yards from that part of the line where most of the cases occurred They were hand carried back to the A D S by trench or across country, but this could only be done in daylight for very exceptional cases From the A.D S to the M D S was 4000 yards, including an ascent of 200 feet and a descent of 500 feet Over this stage cases were taken by litter or travois, but evacuation originally was only permitted by night At a later stage the general officer commanding the brigade holding this part of the line gave permission for mules to be sent over the hill in daylight, and the following order was published "The waiting litter may be sent down in daylight with any abdominal case, severe case of hæmorrhage, or of fracture of a long bone, especially of the femur, and such other case as the officer in charge of the A D S thinks may urgently need immediate evacuation Injuries of the head or chest should not normally be classed under this last head." From the M D S to the C C S was a journey of ten miles along a road, and all the serious cases were sent down, under the charge of a selected orderly, in litters as being less likely to shake the patient than an ambulance wagon The rate of movement of the litter along the road is the same as that of an ambulance wagon On one occasion, owing to a danger of the dressing station getting overfull, we wired for a motor ambulance, but found that the time taken up in getting the wire through and for the motor ambulance to arrive was so much that the patient would have arrived earlier at the C C S had we ordered a litter from our own transport at the same time as we sent off the signal message There was therefore no advantage in either form of ambulance wagon over the litter, and this certainly had the advantage over them of shaking the patient less

Fractures of Long Bones

CASE 1 —Sergeant —— sustained a gunshot *wound* thigh (left) with fracture of the femur and arm (left) at 1.10 A.M on May 30th He arrived at the A.D S at about 3 30 A.M where the large arm wound was dressed and the lower limb put up in a Thomas's splint by Captain Milton From here he was sent on to the M D S on a litter with the limb swinging from an iron bar and his body propped up with a back rest fixed to the stretcher He reached the M D S at 7 A.M and was sent on at once to the C C S where he arrived at 11 A.M He was therefore 9 hours 50 *minutes* on the journey including the time taken to dress him and to put on the splint This was our record for rapid evacuation and was a most creditable performance for all persons concerned It was not reached until we had been in this part of the line for two and a half months

Unfortunately at the C C S signs of gangrene appeared in the toe of the left lower limb and an amputation was necessary a streptococcus was isolated from the lower limb and the *Bacillus perfringens* from the upper limb and he died a short time after the amputation

CASE 2 —Private —— is a more successful case of a fracture of the femur He was wounded on the same piece of ground as the last case at 4 A.M on May 17th He was put up in a Thomas's splint by Captain Milton at the A.D S and went on to the C C S with the greatest comfort Here he was operated on and treated by Carrel's method and when seen by the writer at the base on May 30th was doing very well indeed

Cases Illustrating the Question of Morphia Administration

CASE 3 —Private —— received multiple gunshot wounds of both lower limbs the left arm face and penis Most of these were small in character He was wounded at 2 A.M on May 9th and reached the

M D S at about 9 A M His lower limbs were first dressed by cleaning and shaving and application of gauze soaked in eusol with back splints on each limb At the same time the part of the head round the scalp wound was shaved and dressed Attention was then paid to the left arm Here there was an entirely different type of wound The biceps was blown away with the brachial artery and median nerve completely divided Two things were clear: that he could not be sent on without this vessel being secured and that he was not then in a fit state for an anæsthetic after the long dressing to which he had already been subjected No note had been made on the Field Medical Card that the most important wound was on the arm Had such a thing been done attention would have first been drawn to it and the other wounds might have been left till later At 5 P M an anæsthetic was given and Captain Price Harris ligatured the brachial and redressed the arm The man was sent on next morning already toxic He had his arm amputated at the C C S on arrival but died within the next 24 hours

It is possible that this is the only case which has been through our hands in which an amputation should have been done in the M D S It is probable that short of this we should have done a complete excision of the wound and not have been satisfied with mere ligature of the vessel We might easily have sent him down the line earlier than we did Every step that we took in this case was either wrong or done in a hesitating manner The patient had been given ½ gr of morphia soon after he was wounded and we never knew whether his condition was due to the morphia or to his wound Had we been on firmer ground we might have saved 24 invaluable hours and possibly his life Indecision in such cases is bad surgery but it is very hard to come to a decision under the circumstances

Case 4 —Private —— was a similar case He was wounded in the abdomen at midnight on May 9/10th and arrived at the M D S at 7 A.M He had had ½ gr of morphia He was restless and pale but it was hard to say whether he was under the influence of morphia or suffering from hæmorrhage An abdominal case was just leaving the M D S for the C C S so another litter was at once ordered and he arrived at the C C S alive at 11 A M with a slightly better pulse than when he had left the M D S but died within about four hours This patient would have probably died in any case and he did not suffer from any indecision on our part but we were quite in the dark over it and when he left the M D S I warned the orderly that he might die at any stage of the journey It may be noted that the time from receipt of wound to arrival at the C C S was 11 hours which was the time taken with practically all the abdominal cases when they were hurried through as quickly as possible

Abdomino-thoracic Wounds of Left Hypochondrium

Case 5 —Private —— received a bullet wound in the left chest below and lateral to the apex of the heart and a wound of exit was found at the bottom of the back of the left chest. Through this protruded a piece of what was taken to be lung by the medical officer in charge of the battalion but which was recognised as being spleen by Captain Milton at the A D S Here he was put into a chair made by Corporal Radmore, R.A M C (T) for carrying a patient in the Fowler position This is built on a pair of stretcher poles so that the body is inclined at an angle of 45° with the vertical and the hip- and knee-joints are bent at an angle of 90° All our abdominal and thoracic cases have been carried in this during the last three months Captain Milton reports that the change in the man when put into this was most marked he stopped groaning at once and shortly fell into a comfortable sleep so that the dose of morphia which Captain Milton had intended to give became unnecessary

On arrival at the M D S the patient was in a very bad condition It was argued that if he were sent on to the C C S he would die before arrival if he were kept without anything being done he would as surely die, that his condition might be due to the fact that he was still bleeding internally, and that an operation might control this hæmorrhage and give him a chance of life The abdomen was opened The spleen was found divided in two with half sticking through the wound of exit. There was a large rent in the diaphragm with the stomach and splenic flexure high up in the thorax but bleeding had stopped and there was little or no blood in the cavities The diaphragm was sutured but he died while the abdomen was being sewn up

The surprising thing in this case was that he stood so much before he died Had we left him alone he might have stood a chance The writer read Colonel Wallace s second Lettsomian lecture soon after operating on this case and found that it came under two of the indications which he gives for leaving alone an abdominal wound—namely when the patient is so ill that it is doubtful whether he will stand any operation and in cases involving both thorax and abdomen in the left hypochondrium The decision to operate was partly based on what was found in Case 6, while Case 7 illustrates what should have been done

Case 6 —Private —— was wounded at 10 P M on May 20th and died on the journey to the M D S at about 4 15 A M on the 21st There was a large wound through which pieces of the tenth and eleventh left ribs were sticking and a smaller one below the level of the twelfth left rib Post mortem it was found that the small wound was the wound of entry and from here one part of the missile had entered the abdomen near the left kidney while the other had passed into the chest and out through the upper wound There was a small injury to the lower margin of the left lung without any appreciable loss of blood into the left chest but the left side of the diaphragm was pushed up to the level of the nipple with blood in the lesser sac This was not investigated further owing to the difficulties under which the necropsy was done

Case 7 —Private —— was wounded at 11 P M on June 1st and arrived at the M D S at 2.50 A M, thought to be suffering from a wound of the abdomen from a missile which had entered the lower part of the left chest. His pulse was 150 and his general condition so bad that we did not even take him out of the Radmore chair in which he had been brought down from the A D S He was raised up on a pair of high tressels and a heating stove put under him with bivouac sheets hanging on either side to send the heat up In this way we tried to imitate the electric heat bath advocated by Colonel Wallace He improved considerably but unfortunately we overdid it slightly and he broke out into a sweat which reacted on the pulse At 10 A M he was carefully lifted on to the operating table, the bandage was cut up and the abdomen examined No evidence could be found of any intra abdominal injury except that on passing water the last ounce or so contained changed blood There was dullness at the base of the left lung and as we were examining him hyper resonance made itself evident over the front of the chest and the heart began to become displaced He was infused per rectum and left lying on the table till 3 P M when he was fit enough to be dressed The chest was firmly strapped and the patient put back in the Radmore chair and given a small dose of morphia. Here he slept quietly for four hours and in the cool of the evening was sent on in a litter to the C C S where he arrived at about midnight. Next day he was doing well the heart was then displaced over to the right side of the sternum

In the writer s opinion these cases support Colonel Wallace s advice that abdomino-thoracic wounds of the left hypochondrium should be left alone There is always the fear in the surgeon s mind that bleeding still continues and must be stopped at all costs but it may have stopped of its own accord and had Case 5 been treated in the same way as Case 7 I think the man s life might have been saved

Sometimes the diagnosis of a superficial muscular wound of the pectoral region from an intra thoracic injury is difficult in the early stages

Case of Multiple Wounds Operated on at M D S

Case 8 —Gunner —— was wounded near the A.D S at 7 30 P M on May 31st He had a large wound of the right upper arm and chest wall, which had taken away most of the muscles of the front of the arm and anterior axillary wall another of the right forearm on the flexor surface which had left the deep fascia exposed over a circular area of four inches diameter and a wound of the chin which had vertically split the lower lip and shattered the jaw Captain Milton reports that he observed surgical emphysema in the chest wound and sent him down as an intrathoracic injury in the Radmore chair On arrival at the M D S at midnight his pulse was 104 and weak his dressings had come through but in consideration of the chest injury it was thought advisable to leave him alone By 3.30 A M the pulse had risen to 120 and the bleeding was continuing He was put on the table and the wounds examined There was now no evidence of intra thoracic injury but it was clear that points must be picked up from among the muscles to stop the bleeding It seemed well to do the whole operation An anæsthetic was administered by Captain Rawson The large arm chest wound was excised with most of the pectoralis major muscle and portions of the pectoralis minor biceps, deltoid and latissimus dorsi the forearm wound was similarly treated and Carrel s tubes were inserted Captain Petley then operated on the mouth in the same way and removed several pieces of bone including the attachment of the genial muscles His tongue then fell back and had to be held forward with a suture On taking off his trousers to put on pyjamas a small piece of metal the size of a tin tack was found sticking into the skin a quarter of an inch lateral to the right patella. This had probably entered the knee joint and it was clearly necessary to operate on it His mouth condition prevented us sending him on and it was clearly undesirable to give another anæsthetic within a couple of hours of the first We therefore infused him per rectum and after having dressed and breakfasted, lifted him on to a stretcher with a back rest fixed on it Captain Petley excised the skin and fasciæ with the piece of metal *in situ* A hole one-eighth of an inch in diameter was seen in the synovial membrane This was sewn up and 5 c c of ether were injected from the mesial side The limb was put up in a Thomas s splint and the end slung to an iron bar fixed to the stretcher By 5 P M he had sufficiently regained control over the muscles of his tongue for him to be sent on in safety He was sent off at about 7 P M when it had become cool enough for travelling to be pleasant

We have had the opportunity of following this case through the C C S to the general hospital. He has so far had an uninterrupted recovery secondary suture of the mouth wound was performed on June 12th and on the 15th when we saw the dressings changed the arm wound was doing well and was much smaller than when originally seen The knee-joint had never shown any signs of synovitis This case exemplifies the importance of treating all cases wounded near a joint as though the joint was involved The next teaches the same thing from the other point of view

Case of Wound near Joint —Buttock Wound

Case 9 —Lance-Corporal —— orderly to the medical officer was assisting the latter at about 2 P M on March 20th to dress a wounded man when another shell fell near them wounding him in the right forearm with fracture of both bones and spattering his left lower limb Owing to the question of observation he could not be got away till after dark and did not arrive at the M D S till about 10 P M One of the wounds on he left lower limb was on the mesial aspect of the thigh 4 inches above the lower end of the femur The wounds were dressed in the ordinary way and a back-splint put on Doubts were entertained at the time as to whether this wound might have involved the joint but he was not treated as though it had—that is the limb was not put up in a Thomas s splint and the case was not sent on at once so as to ensure early operation but was kept until 6 A M. next morning and sent off then

He was seen at the base on May 30th He did not look as though he would recover He had suffered for a long time from a raised temperature associated with a suppurative arthritis of his knee-joint A streptococcus had been isolated from the blood Two days later the limb was amputated and when seen on June 15th he looked distinctly better

Case 10 —Private —— exemplifies the advantage of looking upon all cases of buttock wounds as potential injuries of the abdominal cavity He was wounded in the upper part of the left buttock at 1.30 A M on May 25th and was sent down in the Fowler position on the Radmore chair arriving at the M D S at 7 15 A.M and the C C S at 11.55 A M. so that the whole journey was 10 hours and 25 minutes He showed no signs of abdominal injury while in the field ambulance but in the C C S two holes in the gut were sewn up and a bleeding mesenteric vessel secured.

I have been able to follow through these cases by the kindness of Colonel T Crisp English and Lieutenant-Colonel Kelly, who each gave up a day to taking me around the stationary and general hospitals of this force during a period of three days leave at the base

NOTE ON
THE GERMICIDAL POWER OF FLAVINE

BY R TANNER HEWLETT, M D LOND,
F R C P LOND, D P H,
PROFESSOR OF BACTERIOLOGY IN THE UNIVERSITY OF LONDON

(From the Bacteriological Department King's College, London)

THE following few experiments were undertaken in order to obtain data respecting the germicidal power of flavine It will be remembered that Browning and his co-workers[1] claim that in flavine we possess a germicide which is very potent and which is much more active in the presence of serum than in, say, peptone water For the staphylococcus flavine is stated to be germicidal in 24–48 hours at 37° C in a strength of 1 20 000 in peptone water and in 1 200 000 in serum Flavine is also stated to possess comparatively low inhibitory power on phagocytosis

First of all some criticisms of Browning's technique and results may be made before detailing my own experiments

1 In the tests made with staphylococcus and *B coli* the organisms were cultured in peptone water (a poor culture medium) and a 1 20 000 dilution of the 24 hour culture was employed in the tests A loopful of such a dilution yielded "20 or more colonies" In other words, a *very* small number of organisms is the subject of the test In my opinion such a method of testing is fallacious and likely to suggest a germicidal power far above the actual one In all disinfectant experiments a volume containing hundreds at least, if not some thousands, of organisms should be subcultured The reason for this is that the destruction of bacteria by a germicide follows the course of a logarithmic curve if the number of bacteria surviving at successive time intervals be plotted That is to say, there is an enormous destruction of organisms at an early stage, but a small number survives for some time If only a few organisms are subjected to experiment this factor may be entirely masked

2 A great point is made of the increased germicidal power of flavine in serum and apparently the inference is deduced that a similar potency will be exerted upon organisms in pus But is such an inference legitimate? It is very questionable if serum and the purulent discharge of a wound are at all comparable It is well known that serum is a poor culture medium for many organisms (Browning found that *B coli* grows so poorly in serum that it was necessary to add peptone water to it in order to obtain a suitable culture !), while the purulent discharge of a wound may be swarming with organisms In the only experiment with pus quoted flavine 1 2000 was required to sterilise it (a streptococcus + staphylococcus pus), a very different result from serum in which 1 200 000 is stated to be efficient !

3 The germicidal action of flavine is so slowly exerted that Browning adopted not less than 24 hours contact in his experiments I question whether a germicide which is so slow in acting is going to supersede germicides which, even if less potent are much quicker in acting

4 A considerable point is made of the comparatively low toxicity of flavine for leucocytes in phagocytosis experiments The method was to incubate the flavine + serum + leucocyte mixture for 20 minutes and to ascertain what strength flavine inhibited phagocytosis, it was found to be 1 500 Can any inference be deduced from such a test? Surely if the toxic action of flavine on bacteria is so slowly exerted that it requires 24 hours to be completed a similar time should be adopted were it possible for phagocytosis experiments, otherwise there is no comparison between the two for the toxic action on leucocytes might be similarly slowly exerted

I will now pass on to the experiments I have made to test the potency of flavine as a germicide and antiseptic

1 *Inhibitory Power of Flavine on the Development of Organisms of the* B perfringens *Group in Milk*

A similar quantity of dust was placed into each of eight test tubes Recently boiled milk and flavine were added the tubes were heated to 80° C for 15 minutes and incubated anaerobically for three days

The following were the results —

	Milk	Flavine 1 per cent		Result
1	9 0 c.c	1 0 c.c.	– 1 1 000	–
2	9 5 c c	0 5 c c	= 1 2,000	–
3	9 75 c.c	0·25 c.c	= 1 4 000	–
4	9 9 c c	0 1 c c	= 1 : 10 000	+
		Flavine 0 1 per cent		
5	9 0 c c	1 0 c c	= 1 10 000	+
6	9 5 c.c	0 5 c c	= 1 : 20 000	+
7	9·75 c c	0·25 c c	= 1 : 40 000	+
8	9·9 c c	0 1 c c	= 1 : 100 000	+

From this it will be seen that in a highly albuminous medium the inhibitory power of flavine upon the development of organisms of the *B perfringens* group lies between 1 4000 and 1 10,000

2 *Germicidal Power of Flavine upon the Staphylococcus in Broth*

5 c c of broth were inoculated with 0 05 c.c of a 24 hour broth culture of *Staphylococcus aureus* and flavine was added The mixtures were incubated at 37° C and 0 1 c c subcultured into broth after 9 hours and 24 hours Result —

			Result after—	
	Flavine 1 per cent		9 hours	24 hours
1	0 1 c c	= 1 5 000 approx	–	–
2	0·05 c.c	= 1 10 000	+	–
	Flavine 1 : 1000			
3	0 1 c c	= 1 50 000	+	+
4	0 05 c c	= 1 : 100 000	+	+

From this it is seen that the germicidal power of flavine on the staphylococcus lies between 1 5000 and 1 10 000 for a 9 hours exposure, and 1 10,000 and 1 100 000 for a 24 hours' exposure This experiment was repeated with an identical result Under the conditions of experiment flavine is an active germicide, but the number of organisms acted upon, though much greater than employed by Browning, is not large

3 *Germicidal Power of Flavine upon the Staphylococcus in Saline*

An experiment similar to Experiment 2, but substituting saline for broth The results were the same as in Experiment 2

4 *Germicidal Power of Flavine upon the Staphylococcus in Saline*

An experiment similar to Experiments 2 and 3 but using a larger number of staphylococci A saline emulsion of an agar culture was made containing approximately 4000 million cocci per c c

Emulsion	Saline	Flavine, 1 per cent		Result
1 c c	0·5 c c	0.5 c c	= 1 : 400	–
1 c c	0·9 c c	0 1 c c	= 1 : 2,000	–
		Flavine 0·1 per cent		
1 c.c		1·0 c.c	= 1 2,000	–
1 c c	0 5 c.c	0 5 c c	= 1 : 4 000	+
1 c.c.	0 9 c c	0 1 c c	= 1 20 000	+

Using a larger number of cocci, the result is that the germicidal power of flavine lies between 1 2000 and 1 4000—a considerable drop compared with the results of Experiments 2 and 3

5 *Germicidal Power of Flavine upon the Staphylococcus in Human Serum*

Strengths of flavine 1 100,000 1 200 000 and 1 400 000 were first tested, none killed Then the following mixtures were made and to each was added 0·05 c c of a broth culture of staphylococcus Results —

Serum	Flavine 1 2000		*Result*
4 c.c	1·0 c c	= 1 10 000	–
4 25 c c.	0 75 c c	= 1 15 000	–
4 5 c.c	0·5 c c	= 1 : 20,000	+
4 8 c c	0 2 c.c.	= 1 : 50,000	+
4 9 c.c.	0 1 c.c	= 1 : 100 000	+

The germicidal power of flavine *in serum lies, therefore,* between 1 15 000 and 1 20 000 *This is* a very different result from Browning's 1 200,000

6 *Germicidal Power of Flavine upon the Staphylococcus in Pus*

The pus was a pure staphylococcic one derived from an abscess in the neck. 1 c c of pus was mixed with 1 c c of the flavine solution, and after incubation loopfuls were sown into broth and on to agar Results —

---

[1] Browning Gulbransen Kennaway and Thornton Brit Med Jour 1917 vol i p 73 (also ib vol ii p 70)

Flavine solution used	Flavine strength in mixtures	Result after incubation of subcultures			
		24 hours		48 hours	
		Broth	Agar	Broth	Agar
1 100	1 200	—	—	—	A few cols
1 : 500	1 : 1 000	+	+		
1 : 1 000	1 : 2,000	+	+		
1 : 10 000	1 20 000	+	+		
1 100 000	1 : 200 000	+	+		

Here even 1 200 flavine did not completely kill the staphylococcus in the pus, judged by the agar subculture (I believe that on the whole agar is a better culture medium than broth for disinfectant experiments), or if we take the broth subcultures, then the germicidal strength lies between 1 200 and 1 1000

All the mixtures of flavine in the foregoing experiments were incubated for 24 hours before subculturing, unless otherwise stated

Conclusion

From the foregoing experiments the germicidal value of flavine comes out very much lower than that stated by Browning and his co-workers The difference between the two sets of results is probably due to the use in my experiments of a number of organisms much larger than that employed by Browning and his co-workers The result with pus is particularly poor and many disinfectants equal or surpass it and have the advantage of a much more rapid action

Addendum —The above note was written before the appearance of Mr Alexander Fleming's paper in THE LANCET of Sept 1st (p 341) and no alteration has been made in it It will be seen that both in our criticisms and in the results of our experiments there is a general agreement between Fleming and myself.

THE OPEN-FLAP METHOD OF TREATING PERFORATING BRAIN WOUNDS

BY J G HUNT, M D, C M ONT,

MAJOR, CANADIAN ARMY MEDICAL CORPS; LATE OF NO 1 CANADIAN GENERAL HOSPITAL.

EVER since the early days of the war, and more especially before the introduction of steel helmets greatly reduced their number, the problem of how best to handle perforating wounds of the brain has been of absorbing interest The great question following the recovery of the patient from the initial shock resolves itself into our ability to assist nature in isolating the infected area during the period of repair

Though much has already been written on this subject I wish to present for consideration a simple method which, so far as I am aware, has not been used outside No 1 Canadian General Hospital It is one which in the hands of those of us here—Major Mackenzie Forbes, Major S R Harrison, Captain Johnson, and myself who have used it—has given most consistently gratifying results It is based on sound elementary surgical principles—to wit, unobstructed drainage and minimum interference with the damaged parts not only at the time of operation, but during the subsequent weeks of healing Major Forbes, since returned to Canada, was the first to suggest two years ago the leaving down of the flap, but the technique as developed since has been radically changed and simplified

Description of Method

The first step in the operation consists in the turning down of a good sized flap of scalp with perichondrium sufficient to expose freely the whole area of bone injury This flap should, if possible, include the infected wound of entrance

Next, the wound in the bone is enlarged, all depressed fragments being removed, and in addition a margin of healthy dura surrounding the damaged portion of the membrane is exposed. The wound in the dura and brain is disturbed as little as possible Foreign bodies, metal or bone, are only to be sought for if shown, by localising X rays, to be quite superficial. The opening in the dura, if small, should, when the brain is much damaged, be freely enlarged by radiating incisions extending, if need be, to the limits of the bony opening, thus obviating any subsequent constriction of the neck of the hernia cerebri which develops

The next step in the operation is most important A strip of iodoform gauze is firmly inserted between the dura and the overhanging edges of the bony hole The action of this is two fold It, in itself, primarily shuts off the general meningeal space from the infected wound, and subsequently stimulates the formation of the natural barrier of adhesions between the coats of the dura A loose pad of fluffed iodoform gauze is then lightly packed over the whole denuded area

The scalp flap may then be loosely replaced over the gauze, or it may, if considered desirable, be held down (or up) out of the way by one or two silkworm sutures The outer dressings are of plain gauze moistened with saline or boric solution, and should be changed twice daily The iodoform gauze must not, however, be disturbed for from five to seven days. At this date hernia cerebri will be found well developed, and not infrequently, enmeshed in the gauze, will be found small fragments of bone which at the time of operation were buried deeply in the soft substance of the brain, but which have, as Sir George Makins suggests been extruded by intracerebral pressure along the path of least resistance

Cerebral Herniæ

Just a word here on the subject of cerebral herniæ Opinion is divided as to the chief causes of their formation in these cases, some claim that it is entirely due to reactionary increase in the quantity of the cerebro-spinal fluid, and advocate lumbar puncture Personally, I do not believe that this is the chief factor, and my experience of puncturing, done with the object of expediting recession of the hernia in two of the cases which I shall presently report, was not conducive to a repetition of this treatment. Moreover, it is practically not indicated when this technique is followed, since the intracerebral pressure does not unduly rise, if one may judge from the results of frequent fundus examinations In no case was there more than 1 diopter of disc-swelling at any stage, and usually much less Although having no microscopic proof, I incline to the view that the hernia in these cases is largely produced by an analogous process to that which occurs in other parts of the body during the healing of a wound—i e, local increased vascularity, inflammatory œdema, and round celled infiltration.

Whatever be the cause, the fact remains that we can confidently prognosticate the projection of a portion of brain through the wounded dura in the form of a more or less necrotic mass of varying dimensions, except in those cases which are previously overwhelmed by the gravity of their local lesions What, then, happens to this tumour mass if, as was often the case, the flap be re-sutured at the time of operation with or without the use of drainage tubes? In a large number that I have seen—not, fortunately, in all—there was a latent period of from seven to ten days' hopeful convalescence, followed by a sudden rise of temperature and early death from general meningitis The post-mortem findings in these cases showed, beside the picture of a spreading purulent meningitis beginning from the wound margins, that the soft necrotic brain matter composing the hernia had spread out beneath the skin flap and being an ideal medium, had through contact with the wound margins become virulently infected with the result that the limiting adhesions formed by nature had not been sufficient to localise the infection

The subsequent conduct of the case is simple The deep dressing need only be changed bi weekly The hernia reaches its maximum size about the end of the second week and then begins slowly to recede, so that in from four to six weeks it no longer projects above the level of the bony parts, and the whole wound will be found to be covered with healthy granulation The skin flap may now be safely replaced Owing to its elastic retraction it may require a little patience to loosen thoroughly both it and the opposing skin margins to effect good apposition

Results Illustrative Cases

I regret that I am unable to give full statistics covering the actual number of cases that have been treated by this method in our hospital—well over 50 to my personal knowledge—but the results, both as to life-saving and ultimate restoration of function, have unquestionably proved far better by this than by any other method adopted here

The following four cases will serve well, however, to demonstrate what may confidently be expected if this technique be followed. They are selected because of the fact that three of them, in addition to cranial wounds, were complicated by compound fractures of the frontal or fronto-ethmoidal sinuses, thus opening up an additional tract for infection, while the fourth case is that of a rare lesion of the base of the skull involving the cerebellum

CASE 1.—Private E. F aged 32, was admitted on Oct. 16th, 1916, having been wounded four days previously Examination showed a large irregular oblique perforating wound of the right forehead, starting 1½ inches above the centre of the eyebrow and running to almost the inner end of the same. The parts around were swollen, and soft brain matter was exuding from the wound. The right eye was proptosed out and down, with very limited motion vision was reduced to recognition of the figure at 4 feet. Nasal breathing was obstructed The mentality was clear but the patient was depressed and anxious he complained of constant frontal headaches. X ray—two directions—showed a large hole in the frontal bone with presence of large foreign body in post-nasal cavity which was removed with difficulty on account of its size through the naso-pharynx and mouth. Operation next day A frontal flap was turned down the frontal bone was badly comminuted, involving in addition, both plates of the frontal sinus The roof and inner wall of orbit with right ethmoid cells were disintegrated. The flap was replaced on Nov 22nd, five weeks after primary operation, and the wound healed without suppuration.

The functional results in this case were particularly gratifying both as regards sight and brain function, and for two weeks before discharge to England the man was able to do light hospital duty

CASE 2.—Lance Corporal D., aged 20 was admitted on Sept. 19th, 1916. Examination showed a through-and through wound of the head, entrance in front of the right ear exit about the middle of the forehead, half an inch above the level of the eyebrow The patient was rational but very low-spirited— wants to die." There was constant frontal headache the right eye was destroyed, and soft brain was oozing from the frontal wound. X ray of the head was negative for foreign body In this case a single flap could not be used, so after removing the eye, an incision similar to that used in the radical frontal sinus operation was made and the soft parts retracted.

In this case the large hernia had receded and the wound was closed six weeks after the primary operation. It is worthy of note however, that it was found much more difficult to close than those cases where a good-sized single flap had been utilised. The functional recovery was complete except for the loss of his eye

CASE 3.—Private W aged 21 was admitted on Nov 7th 1916 Examination showed a small, perforating wound half an inch over the centre of the left eyebrow with soft brain and fluid exuding At the operation it was found that the wound in the frontal bone communicated with the frontal sinus, which contained a quantity of bloody offensive pus A fissured fracture of the inner table of the frontal sinus extended down to the infundibulum. In this case in order to determine whether lumbar puncture might hasten the recession of the hernia, on the fourteenth day after operation 15 c.c. of fluid were drawn off no immediate result was observable, but on the next day there was marked reduction in the size of the hernia, and by the sixteenth day not only had it disappeared, but it had become a negative quantity so that, in lieu of a tumour there now presented a distinct cavity in the anterior lobe of the brain, the size of a pigeon's egg The patient at this time complained of severe recrudescence of headache and his general disposition became markedly depressed. Nothing was done except to dress the cavity daily and by the twenty-fourth day it had become almost occluded by approximation of its walls. On Dec. 7th four weeks after operation the flap was re-sutured In spite of the fact that the bone over a considerable area beneath the flap appeared dry and dead looking primary union occurred.

CASE 4.—Private D., aged 23 was admitted on Nov 15th 1916. The patient had had an operation at a casualty clearing station and the wound had been sutured. The diagnosis received was shell wound cerebellum right fragment of shrapnel removed Two days after admission he complained of increasing headache, and the wound broke down in the centre discharging soft brain matter In this case a posterior flap was turned backwards, and held in place by sutures Hernia of the cerebellum, much disorganised, was found to be present beneath the skin flap In this case, on the eighth day after operation there was a thin fragment of bone extruded into the dressing an inch and a quarter long and a quarter of an inch wide. This patient also was subjected to lumbar puncture at the end of the second week, with similar results, though not so extreme, as in the last-quoted case. The hernia did not entirely disappear but there was marked disturbance of the patient's *bien-être*, with recurrence of headache and leakage of serum which I attributed to the traction on the protective barrier of dural adhesions around the bony opening The flap was successfully closed at the end of the fifth week, at which time there were no functional evidences of cerebellar anomaly

AMBULANCE TRAINING IN INDIA.—From a statement issued by the headquarters of the St. John Ambulance Association in Simla it appears that during the nine months ending June 30th 1917 the St John Ambulance Association in India and Burma instructed 11,955 persons in first aid to the injured 787 in home nursing 1216 in home hygiene and 65 in sanitation Of these 5962 have been awarded certificates 165 vouchers 55 medallions and 27 labels for proficiency in first aid 417 for proficiency in home nursing 309 for proficiency in home hygiene, and 35 for proficiency in sanitation

A NOTE ON MEDIASTINITIS AS A CAUSE OF HEART FAILURE

By H LAWSON WHALE, M D CAMB., F R C S ENG.,
CAPTAIN R.A.M C (T) — STATIONARY HOSPITAL, B.E.F

AFTER a massive gunshot wound of the neck, resulting in a gangrenous cavity which involves most of one or both anterior triangles, the possible causes of death are obvious, such are secondary hæmorrhage septicæmia, or, if the air-passages are involved, septic pneumonia In these cases it is not necessary to invoke a spreading infection in the cervical fascial planes to explain the result. In a second class of case a cellulitic spread of infection must be admitted, and is indeed apparent I refer to small wounds which, communicating with the retropharyngeal space, initiate a retropharyngeal infection with or without a macroscopic abscess In such an event a spread by the fascial planes is prevented and combated by surgical drainage And drainage at this level in the upper and mid-cervical region, is fairly easy But it is otherwise lower down, as we approach the thorax. And there is another, third, class of case much more distressing and difficult to deal with, to which this present note has reference

A patient arrives with a truly insignificant wound anywhere about the neck—so insignificant that, at first glance, surgical intervention would hardly be considered. There are no signs, local or general, of inflammation But, consistent with an increasing difficulty in swallowing or breathing or both, stereoscopic skiagraphy shows a foreign body, which, though quite small, is very deeply placed. The signs of pressure persist and increase, and so the foreign body is removed In less than 48 hours the pulse and respiration rate have increased alarmingly and in fits and starts This, with an erratic temperature, is the only sign that things are going wrong But adequate surgical drainage and cardiac stimulants are unavailing And in a day or two, without having even looked ill or lost his colour, the patient dies

The medical officer before he sees the autopsy would excusably explain such a clinical history by assigning the cause of death to (1) shock, (2) septicæmia, or (3) heart failure Let us briefly consider these.

1. *Shock.*—Due to what? If to the injury, it may be asked why the patient was so well when first seen. If to the operation, it may be stated that this was neither extensive nor lengthy enough to cause shock, which, moreover is hardly consistent with the fact that his tachycardia and rapid breathing alternated with periods of nearly normal pulse and respiration rate, that until the end his colour remained good, and that his temperature was irregular, not consistently low

2. *Septicæmia?*—The patient may have died before there has been time to search for organisms in his blood, so this explanation is suppositious.

3. *Heart failure?*—That this has occurred is clinically obvious, but why should the heart have failed?

Of the following three cases the salient features are quoted, without details to illustrate the onset of vagitis

CASE 1.—Private, admitted August, 1916, with a small clean incised wound 1 inch long over the thyroid cartilage Except for this the whole neck was, and remained until death, normal. Temperature was intermittent up to 101° F., pulse up to 100 Respiration rate hovered around normal but dyspnœa and hoarseness were constant and increasing Lungs and heart were normal. Aided by skiagrams, a piece of shrapnel casing 1 inch by ½ inch, was easily removed from over the left lobe of the thyroid gland, just below the level of the cricoid cartilage deep to the infrahyoid muscles, at about the point where the recurrent laryngeal nerve passes beneath the inferior constrictor muscle. The operation wound was dressed with very light packing of ribbon gauze and resulted in instant relief of symptoms. On the second day pulse and respiration rate rose so fitfully that it was difficult to chart Cardiac stimulants proved useless he died on the third day

The operation wound down to the œsophagus was found to be quite clean. In the prevertebral space there was a layer of purulent lymph from the thyroid cartilage to vertebra D 2 involving both vagi.

CASE 2.—Private B., admitted August, 1916. A shrapnel bullet which had entered behind the angle of the left mandible and traversed the mouth and palate was removed from the right antrum. The entrance wound which was directed inwards to the prevertebral region, was kept dressed with saline the patient's condition precluded any exploration under an anæsthetic. Temperature was intermittent up to 102° F Pulse varied from 100 to 140. Respirations varied with startling suddenness from 20 to 60 From the second day until his death the left pupil was widely dilated to 12 mm. with no reaction to light. Lungs and heart were normal. He died on the fourth day

There was a thin layer of purulent lymph in the prevertebral region of the left side from the pharynx to vertebra D 3 this involved the left vagus and sympathetic. There was no macroscopic retropharyngeal abscess

CASE 3 —Private P admitted April 1917 with a clean skin wound ½ inch long in the mid line of the thyro-hyoid space There were no other signs of injury and none of inflammation Temperature was normal He had increasing dysphagia and spasmodic dyspnœa. Stereoscopic skiagraphy showed a foreign body hardly as large as the little finger nail, just to the left of the mid line opposite vertebra C 7 and 2 inches from the front surface of the neck

Operation.—A probe would only pass along the track from the skin wound for 3 inches Since therefore the foreign body could not be removed by this route a formal dissection was made along the anterior edge of the sterno-mastoid tendon It was now seen that the probe in the original track passed deep to the sterno-thyroid muscles and there ceased abruptly The sterno-thyroids and sterno-hyoids were then divided and reflected sufficiently to pass a finger down to the vertebra. Here a small piece of shrapnel was found lying in a pool of turbid grey fluid, which welled up as fast as swabbed away Subsequent staining with osmic acid showed this fluid to be chyle But in case the œsophagus were wounded as well as the thoracic duct, an œsophageal tube was passed The operation wound was drained by tube The operation which lasted 20 minutes was practically bloodless and relieved all symptoms completely

On the following day the patient gradually developed an irregular temperature and spasmodic rapidity of pulse and respiration just like the other two cases On the third day these attacks merged into a chronic tachycardia (160) and rapidity of breathing (40) and the pupils became fixed (3 mm) Heart and lung sounds were normal but diminished There was no hiccough or other diaphragmatic upset to suggest that the missile had injured the phrenic nerve. Cardiac stimulants and oxygen were unavailing The wound remained quite clean and the man s colour good until he died on the fourth day

After death the wound from skin surface to prevertebral fascia, was found to be absolutely clean. But on stripping the œsophagus from the spine a layer of purulent lymph was found from the level of the carotid bifurcation to vertebra D 2 this purulent lymph involved both vagi of which the left was irregularly infiltrated and thickened to ¼ inch for 6 inches of its length. There was no trace of the thoracic duct higher than vertebra D 3, nor any wound of the œsophagus

Commentary —In Case 2 the foreign body passed through the retropharyngeal space The patient therefore belongs to the second of the three classes of cases mentioned in the opening words of this note And naturally the infection spread to the posterior mediastinum, his condition never allowed of operation, and he was doomed This case is mentioned only on account of changes in the pupil of the affected side—which aided in the diagnosis

The two other cases were more distressing, because they were on admission seemingly fairly healthy men, with trivial wounds Despite operative and post-operative care, infection tracked extensively in the planes of the neck. In the light of such findings it is easy to understand why Crile recommended that for such operations as laryngectomy the cervical fascial planes should be opened up several days beforehand, and packed with gauze, so as to stimulate the formation of barriers of granulation tissue, defensive against infective spread

Diagnosis —The temperature is very irregular It may rise to 104° F and again fall, it may remain up or down for only an hour or for two days There is no suggestion of periodicity in the pyrexia The most characteristic feature is the sudden alternation of pulse and respiration rate Thus, in Case 2 respirations in a moment changed from 20 to 60 and then after half an hour again back to 40 Following a deep wound, however small, anywhere in the neck, and although the prevertebral space may not have been obviously opened, this startling alternation (especially if accompanied by an altered size or mobility of one or both pupils, indicating involvement of the sympathetic) forms a symptom-complex. The diagnosis is vagitis due to mediastinitis Such cases are, as stated above, often diagnosed simply as heart failure, shock, and so on.

Treatment —The changes may be rung on cardiac stimulants with no success Surgical cleansing of the wound right down to the spine is no safeguard It would naturally seem that in the after treatment of very deep wounds in the neighbourhood of the thoracic inlet posture is important We should, as a matter of course, wish the patient to lie, if not on his face, at least semi prone on the affected wide, with the head low But with the acceleration of pulse and respiration orthopnœa is insistent, and it is not possible to keep the patient lying down. The anatomical difficulties of good surgical drainage at the thoracic inlet are great

---

DONATIONS AND BEQUESTS —The late Dr John Henry Bartlet, of Birkfield, Ipswich, Suffolk, senior surgeon and honorary consulting physician to the East Suffolk and Ipswich Hospital, after making provision in his will for a number of legacies, including £100 to the Suffolk Convalescent Home left the residue of his property, about £200,000, to the East Suffolk and Ipswich Hospital for a home of recovery for invalids

Reviews and Notices of Books.

Les Fractures de la Mâchoire Inférieure By L IMBERT and P RÉAL With 97 figures and 5 plates Paris Masson et Cie 1917 Pp 151. Price 4 francs

THIS manual is the combined work of L Imbert, of the School of Medicine of Marseilles, and P Réal, a well known dental surgeon. This is an ideal combination of activity, for gunshot injuries of the jaw beyond ordinary surgical treatment require for the manufacture of proper splints the aid of those specially trained in dental surgery The work of Claude Martin has had a profound influence on those treating this type of injury, with the result that the main object in treatment has been to restore the teeth to their normal occlusion, even at the risk of only obtaining fibrous union Against this method the authors enter a strong protest and maintain that osseous union should be the goal, providing that in obtaining it the function of the teeth can be maintained The authors advocate that in cases of non union the edge of the fragments should be freshened and the parts fixed by metal plates The results, they consider, are satisfactory The reader turns with interest to the section on bone grafting to see if the authors have been able to elaborate a method which will ensure success The results recorded are not gratifying There is a very full account of the various appliances used for immobilising the fractured jaw as well as a valuable note on the question of compensation for injuries of the jaw

The authors take up a practical standpoint, and it is interesting to note that the views advocated are almost identical with those expressed by Mr J F Colyer in his papers published in the *Journal of the Royal Army Medical Corps* for April, 1916, and the March and April issues this year of the *British Dental Journal*

An Index of Symptoms, with Diagnostic Methods By RALPH WINNINGTON LEFTWICH, M D Aberd Sixth edition London Smith, Elder, and Co 1917 Pp 555 Price 10*s* 6*d* net

IT is only two years since the last appearance of this compilation, but it is evident that Dr Leftwich's ingenious industry is essential during war time Few new symptoms appear but two minor additions have been made in the light of experience although logically somewhat outside the scope of the book One of these is a collection of brief descriptions of rare diseases to which attention is called in the lists of symptoms, but which the author fears his reader may search for in vain in current text-books Such a fear we should hope to be ungrounded in the case of paratyphoid fever, tetany, and some others that might be enumerated A list of eponymous signs now facilitates reference to further symptoms when the spoor of a disease has been a sign with an individual name attached—e g , under Deafness, Nervous, the names are given of Bárány, Dundas Grant, Gardiner Brown, Schwabach, and Weber The book remains in its new edition a sound display of logical discrimination and of restraint in its application It might fairly bear as a sub-title, "The Essentials of Diagnosis " In future editions the electro-cardiogram might suitably find a place alongside the sphygmogram

---

The Practitioner s Medical Dictionary By GEORGE M GOULD, A M , M D Third edition, revised and enlarged, by R J E SCOTT, M A., M D London H K Lewis and Co Pp 962 Price 17*s* net

THE third edition of this dictionary contains, so the compilers estimate, 20,000 new words, and the addition has been made without detriment to the compactness of the volume by the use of thinner paper, slightly reducing the size of the type and omitting unnecessary illustrations The result fully justifies the labour expended on its production, the book as it now stands being complete, accurate, and up-to-date as well as very pleasant to handle During nine months' constant use we have failed to find any important omission The dictionary is a little more inclusive than the title implies as in addition to derivations, formulæ are given and the dates of birth and death of those who have given their names to diseases or symptoms The book may be recommended as a desk companion to all practitioners who wish to read intelligently and to write accurately

Anæsthetics A Practical Handbook By J BLOMFIELD, M D Cantab Fourth edition. With numerous woodcuts London Baillière, Tindall, and Cox. 1917 Pp viii. + 147 Price 4s net

Dr Blomfield's book maintains its high character for usefulness It is a model of condensed statement and intended, as it is, for beginners in the art of giving anæsthetics fulfils its aims admirably The author considers it is best to omit detailed statements about the more intricate methods, such as intratracheal insufflation, intravenous and colonic etherisation, although he mentions the Dämmerschlaf scheme in parturition, spinal and parasacral anæsthesia The chapter on these last methods, we venture to think, might with advantage be put a trifle more fully, and this suggestion applies with equal force to the sections on local and regional analgesia Indeed in these we find that Dr Blomfield still recommends cocaine rather than the use of the novocain suprarenin solutions now usually adopted. We may assume that anoci association is not regarded by Dr Blomfield as a student's method, and so is omitted A useful, if brief, résumé of war methods is added in this edition and should prove valuable The subject of anæsthetics has become so wide that any attempt to envisage it in a small compass presents great difficulties, while the decision as to what should be retained and what omitted is not an easy one, however, we feel that Dr Blomfield has probably done the best possible He writes with much lucidity and his teaching is sound and perspicuous We note that by a slip Trendelenburg is wrongly spelt in several places

LIBRARY TABLE

1. *The Principles of Rational Education* By CHARLES A. MERCIER, M D Lond., F R C P Lond, F R C S Eng, late Examiner in Psychology in the University of London London The Mental Culture Enterprise Pp 87 Price 2s 9d net —2 *The Public School System in Relation to the Coming Conflict for National Supremacy* By V SEYMOUR BRYANT, M A With a Preface by Lord RAYLEIGH 1917 London Longmans, Green, and Co Pp 78 Price 1s 6d net —1 Dr Mercier's book is intended to bring home against the public schools and universities the charge that through their routine the originality has been crushed out of many of his friends, who have been turned loose in the world ignorant of that world and unable to conduct an argument logically or to write intelligible English legibly So much we learn from the prefatory words He proceeds to deal with the standards and aims of education in a brilliant and summary manner, and covers in a few pages so much ground that he cannot expect any journal with a definite scope like THE LANCET, to criticise his opinions in detail, but Dr Mercier might not admit the justice of any criticism unless the authorities for it were set out with particularity, and this would be a very long task, and would also require a wide range of specialised knowledge In some places to explain a disagreement from his conclusions or assumptions would entail—given the ability on the part of the disputant—the writing of a book larger than that in which Dr Mercier aggregates his accusations against the training of our youth along literary or scientific ways Dr Mercier will not be able to convince his readers that he is always right, for indeed, while he tells us much which thinking people believe some of his diatribes are not made just by their wit But at any rate he shakes us out of self complacency and paves the way to reform

2 Mr Seymour Bryant s pamphlet might well be read at the same time as Dr Mercier s essay He deals with education in preparatory schools and the public school curriculum in considerable detail showing the time employed in various subjects and the vagaries of the marks allotted to these subjects making special reference to the evils of classical specialisation and to the failure at most schools to educate their youth either in science or modern languages We take it that the book was largely written for the sake of the chapter in which the role of science in the educational scheme is fully set out and the plea here is that classical specialisation should not hamper the study of natural philosophy A final chapter on constructive policy has been dictated by the author s decision that the existing public school system cannot satisfy the needs of the day and that the only remedy is to replace it by a new organisation He outlines such an organisation, and, to some extent, his ideals of reform would meet Dr Mercier's criticisms

We recommend these two small books cordially to every body, for they cannot fail to make us look closely at the methods under which our young men and maidens, especially youths of the upper and upper middle classes, are educated. If, as a result we find ourselves dissatisfied with the ideals, the practical aims, or the effective results of such education we should be encouraged to help in altering the system

The Medical Annual, 1917 Bristol John Wright and Sons, Limited Price 10s net —This useful "Annual" keeps up its usual standard in the volume for 1917, the thirty fifth year of publication In his brief preface the editor calls attention with justice to the fact that at the present time, when every department of medicine is understaffed there is a remarkable indication of general energy and ability in the pursuit of the healing art The "Annual" has been successful in putting the practitioner in touch with the main results of all this recent energy Of the longer articles we should like to call special attention to those on gunshot wounds and wound infections by Deputy Surgeon General A G Wildey, on war injuries of the jaws, by Mr W H Dolamore, on poliomyelitis, by Dr J R Hunt and Dr F Langmead, and soldier's heart, by Dr Carey Coombs The usual summaries of therapeutic progress, electro-therapeutics, and new inventions appear, and the care and precision with which the work is produced are evident on every page

German East Africa By ALBERT F CALVERT, F C S London T Werner Laurie, Limited 1917 Pp 122 Price 6s net —Mr Calvert gives a succinct account of the early history of the German colony The notorious Dr Carl Peters was the pioneer of the German Colonial Empire in Africa In 1885 he founded the German East Africa Company, endowed with treaties which he had obtained and which professed to give rights over some thousands of square miles This was Germany's largest colony larger than Germany itself, but with a population only of 7½ million natives and 5500 whites Rubber, sisal hemp, cotton coffee, and capok are the chief products Twenty years ago Dr Hindorf imported a few sisal plants from Central America, but of 2000 plants only 72 could be kept alive and yet to-day there are millions of plants cultivated This was the most important product for export at the time of the outbreak of war At the end of the book are collected 219 photographs and maps giving a lucid panorama of places and people

JOURNALS

Quarterly Journal of Experimental Physiology Edited by E A. SCHÄFER, W D HALLIBURTON, C S SHERRINGTON, E H STARLING, and A D WALLER Vol XI, No 1 London Charles Griffin and Co, Limited 1917 Pp 1-126 Price 7s 6d —The Influence of Corpus Luteum Extracts upon Plain Muscle, especially that of the Uterus, by M Itagaki, with Appendix, by W W Taylor That the corpus luteum is a gland of internal secretion was first suggested by Prenant who, in 1898 arrived at his conclusions from the morphological character of the cells The author's methods of preparing the extract and recording the movements of the uterus are described The recording method used was a modification of the method devised by Magnus for the plain muscle of the alimentary canal The uterus of the rat, cat dog, and guinea pig were used The author finds that—

1 Extract of corpus luteum generally produces a distinct increase of tone in the surviving uterus of the rat, rabbit, cat, dog, or guinea pig Rarely, however, the opposite effect is produced 2 This difference of effect is not due to the condition of pregnancy or non pregnancy, nor to varying strengths of the extract, but apparently to a difference in different samples of corpus luteum having an antagonistic action upon the contractions of the uterus 3 These principles can sometimes be separated by alcohol, the inhibitory material going into alcoholic solution But this chalonic substance, which is soluble in water, is very small in amount The hormonic substance, on the other hand, which is generally much larger in amount, is not soluble in alcohol nor in chloroform and ether, but is soluble in water 4 If we compare the action of corpus luteum extract upon the uterus with its effect upon other forms of plain muscular tissue

we find that it generally produces relaxation of the muscular tissue of the intestine and of the bladder of the rat but contraction of the whole intestinal tube of the rabbit and kitten, although when isolated strips of either the longitudinal or circular intestinal muscle of these animals were taken they showed relaxation Upon the iris of the frog no change could be observed 5 Injection of corpus luteum extract into a vein produces but little effect upon the blood pressure, if anything, there is a slight fall 6 A free secretion of milk is caused from the cut nipple of a lactating animal 7 Urinary secretion is not appreciably affected 8 The author was unable to obtain any definite proof that the action of corpus luteum upon the uterus is effected through the nerve endings either of the sympathetic or of the pelvic nerve

The appendix deals with the analysis of ash of corpus luteum of ox.—On the Action of Various Extracts obtained from the Cow's Ovaries upon the Muscular Tissue of the Uterus, Intestine, and Blood vessels, by M Itagaki The author finds that—

1 Extract of hilum ovarii has the opposite effect to extract of corpus luteum upon the movements of rat's uterus, for it causes inhibition instead of contraction The uterus of other animals is affected differently, for in the rabbit, cat, and guinea-pig an extract of hilum usually has the result of producing an increase of tone 2 Liquor folliculi produces an increase of tone of the uterine muscle in the rat, rabbit, and cat, or at any rate an increase in height of the rhythmic contractions 3 When applied to the whole intestinal tube all the extracts tested—hilum, liquor folliculi, and whole ovary—determine an increase of tone, whereas a strip of the longitudinal coat of the rabbit's intestine is sent into relaxation by extracts of hilum 4 A fall of blood pressure is produced by intravenous injection of all the extracts employed—hilum, liquor folliculi, and whole ovary

The Action of Certain Gland Extracts and Drugs upon the Uterus of the Rat, by M Itagaki The following results as summarised by the author were obtained —

1 Extract of posterior lobe of pituitary always produces an increase of tone 2 Solutions of adrenalin inhibit the rhythmic contractions (with or without diminution of tone) 3 Extract of thyroid occasionally produces an increase of tone, but generally has no effect 4 Extracts of orchitic substance, of uterus, and of brain have no appreciable effect 5 The action of nicotine is variable Weak solutions produce an increase of tone, stronger solutions cause first inhibition, then increased contraction, still stronger solutions produce inhibition alone 6 The action of pilocarpine is inconstant, but usually an increase of tone is produced 7 Weak solutions of atropine produce increase of the rhythmic contractions 8 Barium chloride in all strengths which produce any effect causes increased tone and stimulates the rhythmic contractions

The Effect of Thyroid Feeding on the Weight of the Suprarenals and on their Adrenalin Content, by P T Hering The administration of small quantities, 0 2 to 0 5 gm, of fresh ox thyroid daily to white rats increases the size and weight of the suprarenals both in young and adult animals Reckoned in mg per 100 gm bodyweight, the extent of the increase in the 18 male animals examined averages a figure which is equivalent to a rise in weight of from 76 to 78 per cent above the normal This is the result of feeding the animals with the above mentioned doses of thyroid for a period of from three to four weeks Both cortex and medulla participate in the enlargement but the hypertrophy of the cortex is somewhat greater than that of the medulla There is reason to believe that where accessory suprarenals are present they too undergo enlargement The adrenalin content of the suprarenals of the white rat increases, as a general rule, with increase in weight of the animal The amount of adrenalin normally present is about 0 034 mg per 100 gm bodyweight Feeding with thyroid increases the adrenalin content of the suprarenals The average amount in the 18 animals examined averages from 0 049 to 0 052 mg, which is equivalent to a rise in weight of about 50 per cent Owing to the relatively greater increase in weight of the suprarenals resulting from thyroid feeding the percentage amount of adrenalin in them is decreased, though only to a small extent It is probable that the adrenalin in the accessory suprarenals, when these are present, is also increased Rats fed with small doses of thyroid not infrequently die suddenly when apparently thriving In the animals examined which have thus died there is great increase in the weight of the suprarenals and in the adrenalin content The heart is greatly hypertrophied in addition There is evidence that thyroid feeding results in rapid cardiac hypertrophy in white rats —Carbohydrate Metabolism in Relation to the Thyroid Gland II., The Effect of Thyroid Feeding on the Gaseous Metabolism, by W Cramer and R M'Call The experimental observations were made on rats, which, being omnivorous, are specially suited for such observations The present contribution is a sequel to previous studies on the same subject. Observations on the gaseous metabolism in experimental hyperthyroidism confirm the conclusion arrived at on other grounds, that the thyroid secretion produces an increased oxidation of carbohydrates This effect is not due to a direct stimulating effect of the thyroid secretion on the oxidative processes in the cell, but follows upon its action in discharging glycogen from the liver Two stages of experimental hyperthyroidism can be distinguished an "early" stage in which the pre existing carbohydrate of the food and of the deposits in the organism is oxidised When all the glycogen has been removed from the liver a "later" stage sets in in which there is in addition a formation carbohydrate thus formed The "later" stage is characterised by a marked rise in the CO_2 excretion and the O_2 absorption The action of the thyroid secretion on the glycogenic function of the liver lies thus at the root of the increased oxidation of proteins, carbohydrates, and probably also of fats produced by thyroid feeding —Experimental Observations on the Pituitary, by W Blair Bell This paper details the experiments on which Professor Blair Bell delivered a Hunterian lecture last year at the Royal College of Surgeons of England [1] The conclusions come to are as follows —

1 The pituitary body is an organ that is essential to life, its removal causes death within a few hours In the cases which survive for longer periods the removal has probably not been complete 2 The removal of very large portions of the pars anterior is incompatible with life It appears certain from the evidence at our disposal that it is the loss of this portion of the organ that proves fatal when total extirpation of the pituitary is practised 3 Partial removal of the pars anterior may, if sufficient quantity be removed cause genital atrophy This may occur in the absence of any other symptom, although the animal may remain undersized 4 Neither partial nor complete removal of the pars posterior causes any symptom The genital organs remain normal after operation, and young animals continue to develop Hence the secretion of the pars nervosa is neither necessarily beneficial nor essential to life 5 Partial removal of the partes anterior and posterior causes no symptom provided only a small portion of the pars anterior be removed 6 Clamping and separation of the infundibular stalk, by interfering with the blood supply and so causing degeneration in the cells of the pars anterior and intermedia, lead to the condition known as dystrophia adiposo genitalis 7 Artificial tumours in the neighbourhood of the sella turcica may produce irritation, which is accompanied by glycosuria and emaciation, or by interfering with the blood supply may lead to degenerative changes in the cells of the pars anterior, and so give rise to the syndrome dystrophia adiposo-genitalis 8 The pituitary body appears to be one organ, not two, and the essential and beneficial secretion is taken up by the blood stream, as in the case of the other organs of internal secretion

Physiological Abstracts —Issued by the Physiological Society and edited by Professor W D HALLIBURTON Vol II, No 6 September, 1917 London H K Lewis and Co Annual subscription, 25s —The standard of the Physiological Abstracts is well maintained in the September number of that publication, which contains more than 300 abstracts The section devoted to plant physiology forms a considerable and apparently an increasing proportion of the total abstracts, and is particularly valuable to physiologists, who are liable to overlook work done in this field of research There can be no doubt that, as time passes, the value of these abstracts is becoming more and more appreciated, they are especially useful at present when workers have so little leisure to devote to the reading of papers

The British Journal of Surgery Vol IV Bristol John Wright and Sons, Limited Price 30s net —The fourth volume of the *British Journal of Surgery*, under the direction of an editorial committee, of which Sir Berkeley Moynihan is chairman and Major E W Hey Groves secretary, maintains its high standard of excellence Biographical notices with good portraits are given of Sir Charles Ball, Mr Arthur Barker, and Sir Victor Horsley, as well as of two surgical worthies of an older generation, John Woodall and Peter Lowe Sir Alfred Keogh contributes an introductory article on the surgical organisation of the war Accounts are given of the surgical practice of other countries American, by Dr G W

---

[1] See THE LANCET, Feb 19th, 1916 p 420

Crile, Portuguese, by Dr A. H Bizarro, French, by Professor Tuffier The series of illustrations of war surgery by various writers, under the general editorship of Sir George Makins, is advanced another stage, and other groups of writers collaborate in large studies of tetanus and traumatic aneurysm Individual articles under the signatures of well-known experts cover most of the range of war surgery Reviews and notices of books occupy a score of pages A noteworthy feature of the volume is the abundant illustration, some of it in colour, which reflects great credit on the publishers

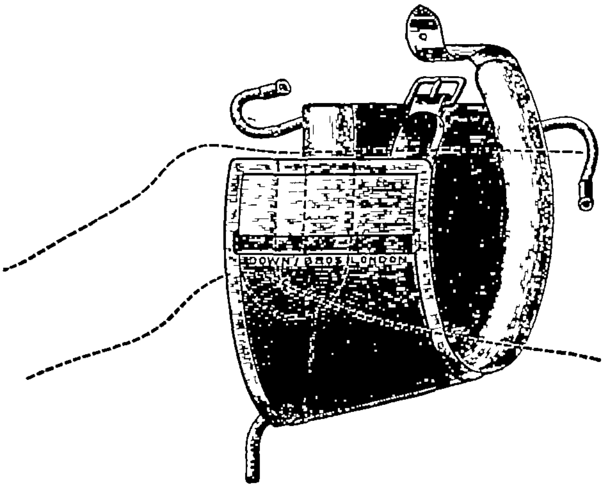
The Annals of Tropical Medicine and Parasitology Vol XI, No 1—The first contribution to this number of the *Annals* is by Dr J W S Macfie and Dr A. Ingram of the West African Medical Staff, the title being "Some Observations on Malaria in the Gold Coast Colony" where an unenviable reputation from the health point of view is disappearing under the considerable improvement in the health of its European officials Malaria, mostly of the subtertian variety, is very common The authors discuss the subject in its various aspects, including the relative frequency of the different malaria parasites, the seasonal incidence of the disease at Accra, the abnormal forms of parasites of the subtertian type, the association of malaria with œdema and the occurrence of anaplasma like bodies in the blood of patients suffering from malaria. This paper is illustrated by two plates and some smaller illustrations in the text—A second report on protozoal investigation of cases of dysentery conducted at the Liverpool School of Tropical Medicine is contributed by Mr Henry F Carter, F E S Dr Doris L. Mackinnon, Mr J B Matthews and Mr A. Malins Smith, Lieutenant-Colonel J W W Stephens, R.A.M C, collaborating in the last part of the report relating to the treatment of histolytic infections It appears that 20 men invalided from France were found to be carriers of *Entamœba histolytica*, 11 of these men had never been out of England before the war, one had been in Belgium, six had been in regions where amœbic dysentery is endemic either during the war or earlier, in the two remaining instances details were not obtained Four of the men had no history of dysentery and declared that they never had diarrhœa at any time, two who had no history of dysentery said that they had suffered from very bad diarrhœa in France for the first time in their lives, the other 14 all had a history of dysentery, 12 having contracted it in France Two men had dysentery before going to France and their attacks there were relapses, one of these had the disease first at Gallipoli, and the other in South Africa 12 years ago It is cases such as these last two that are responsible for introducing amœbic dysentery into the trenches in France although, no doubt, "non-dysenteric" carriers also play a part in the conveyance of the disease—The Occurrence of *Ankylostoma ceylanicum* in West African Dogs is dealt with by Dr Warrington Yorke and Dr B Blacklock, their paper being illustrated.—Dr J W S Macfie and Mr Henry Carter supply a joint paper on the Occurrence of *Spirochæta eurygyrata* in Europeans in England with a note on a second species of spirochæte from the human intestine.—The relapsing fever spirochætes are discussed by Dr J W S Macfie and Dr Warrington Yorke, who from their investigations find that there is no appreciable difference in length between the spirochætes causing European (*S recurrentis*) Indian (*S carteri*) and African (*S duttoni*) relapsing fever The spirochætes including double forms but not multiple individuals range in length from 12μ to 38μ, but are most commonly about 17μ to 20μ long These investigators were unable to discover any morphological distinctions between the spirochætes—A preliminary note on persons, who have never been out of Great Britain as carriers of *Entamœba histolytica* is contributed by Dr Warrington Yorke Mr Henry Carter Dr Doris L Mackinnon, Mr J R. Matthews and Mr A. Malins Smith recording the results of the examination for intestinal protozoa of 344 persons more than half of them being healthy young men who had recently entered the Army and were in training in a camp near Liverpool. Of these at least 10 (2·9 per cent) harboured in their fæces cysts morphologically indistinguishable from those of *E histolytica* By feeding experiments on kittens the cysts in one of these cases were proved to be pathogenic.—A joint article entitled 'Studies in the Treatment of Malaria is furnished by Lieutenant Colonel J W W Stephens R.A.M.C, Dr Warrington Yorke Dr B Blacklock Dr J W S Macfie, and Dr C Foster Cooper This paper, which is illustrated by numerous charts, discusses the intravenous injections of tartar emetic in various forms of malaria including double infections The conclusion arrived at is that intravenous injections of tartar emetic do not cause the disappearance from the peripheral blood of any stage of malarial parasites, whether *P vivax* or *P falciparum*, nor do the injections control either the rigors or the fever of acute malaria A second study in the treatment of malaria by the same authors as in the previous contribution, deals with intramuscular injections of quinine bihydrochloride in simple tertian malaria. As diverse views had been expressed as to the value of such injections, the authors carried out a series of observations, and as a result found that an intramuscular injection of quinine bihydrochloride, 15 grains in 2 c.c of water, on each of two consecutive days caused the cessation of febrile paroxysms of simple tertian malaria and effected the disappearance of all stages of the parasite from the cutaneous blood The action, however, is only temporary, a relapse occurring within two or three days The authors are careful to point out that this refers to simple tertian malaria only They propose to deal with malignant tertian malaria in a future paper As frontispiece to the number there is a very excellent photograph of Professor Mesnil, of Paris.

Parasitology, July, 1917, Vol IX, No 4—The present issue of this journal contains an interesting paper by N H Swellengrebel on "*Blastocystis hominis*," in which the writer states his reasons for disagreement with both Prowazek and Wenyon as to the status of these bodies. He considers that it is highly probable that "*Blastocystis*" is not the name of a zoological genus but of a peculiar form of degeneration to which representatives of several different genera of the intestinal protozoa may be liable In support of this contention he cites two cases, one that of a European who had resided for some years in the Dutch Indies and the other a Javanese temporarily resident in Europe, in whom he could definitely exclude both *Trichomonas* and *Chilomastix*. From the examinations of material in these cases he draws the conclusion that *Blastocystis* cannot, consequently be a normal developmental form of either of these flagellates Swellengrebel further states, in regard to other cases of *Blastocystis* infection which he had investigated that "no blastocysts were found without an associated parasite" Regarding Alexeieff's *Blastocystis enterocola* he considers that it is different from the forms described in man under the same name, as in no case was sporulation observed. This paper is important as marking a distinct advance in our knowledge of these peculiar bodies—T Goodey and A. W Wellings also contribute to this number an important paper on *Entamœba gingivalis* in which they contest the view advanced by Barrett and Smith, that this organism is the causative agent of pyorrhœa alveolaris They consider that the organism, "so far from being a destroyer of healthy tissues in the mouth, is in reality a devourer of waste nuclear material derived from disintegrated salivary corpuscles together with bacteria. and is therefore most probably a useful scavenger" The writers state that they have found *Entamœba gingivalis* to be present in the majority of cases of pyorrhœa, but not in all. They also found it in most cases of gingivitis *not* associated with alveolar absorption. In smears made from the healthy mouth of a child 2 years old the organism was found to be present Goodey and Wellings state as their general conclusions that "there is no evidence to prove that *E gingivalis* is the cause of disease."—T Goodey also contributes a paper on a new trichomonad flagellate *Tetratrichomonas buccalis* which he obtained in material removed from the lower incisors of one of the cases examined in connexion with the above paper This flagellate possesses four anterior flagella and no free posterior flagellum. In stained specimens its length is from 7-12μ. Both the above papers are supplied with excellent plates which illustrate the descriptions in the text—H. Scott furnishes this number with notes on the *Nycteribiidæ* and descriptions of two new genera and E. E Atkin and A. Bacot a paper on the Relation between the Hatching of the Eggs and the Development of the Larvæ of *Stegomyia fasciata* and the Presence of Bacteria and Yeasts Papers on Helminths are contributed by Sadao Yoshida 'Some Cestodes from Japanese Selachians" and K. I Skrjabin, "Sur quelques Nematodes des Oiseaux de la Russie"

New Inventions.

A BATH FOR THE TREATMENT OF COMPOUND FRACTURES OF THE FEMUR

THE difficulty of efficient bathing of septic compound fractures of the femur has been well manifested during the war In the hope of overcoming this and of procuring more rapid aseptic conditions I have had made a bath which can be used with Hey Groves's or the Balkan splint, or with a slightly wider Thomas's splint and a cradle The special features of this bath are as follows It may be employed for (*a*) the ordinary saline or antiseptic bath, (*b*) continuous irrigation, (*c*) Bier's treatment after the bath, (*d*) it may be removed without pain or alteration of the position of the bones or interfering with the extension, (*e*) or it may be left on during the course of treatment when it acts as a special support and splint to fractured bone The accompanying sketch shows the bath in use The bath is made of strong rubber with pneumatic tube at either end, shaped to fit the limb The pneumatic tubes or collars are inflated through a smaller tube provided with a tap, the upper of these may be used by means of an adjusting strap as a Bier's ring A tube conducts the solution from the bottom of the bath over the bedside for continuous irrigation, when an ordinary bath is required the tap provided is turned off The firm portion of metal and rubber offers excellent support for the limb, and in use the bath is very comfortable The malleable metal when covered with the bandage or towel and attached to the top of the splint, or cradle, resists the outward pressure of the pneumatic tube and so makes the bath water tight The removal of the bath is very simple, and performed without affecting the position of the limb



Messrs Down Bros, Limited, St Thomas's street, Borough, S E 1, are the makers

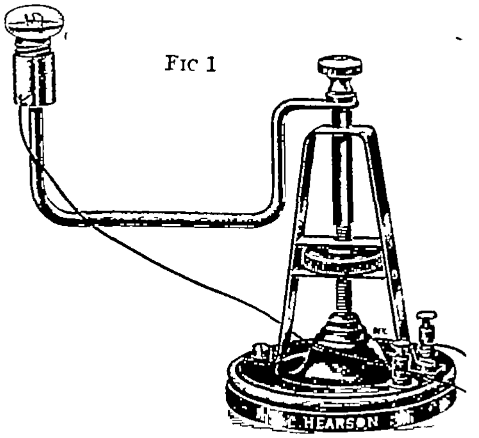
A SIMPLE LAMP FOR DARK GROUND ILLUMINATION

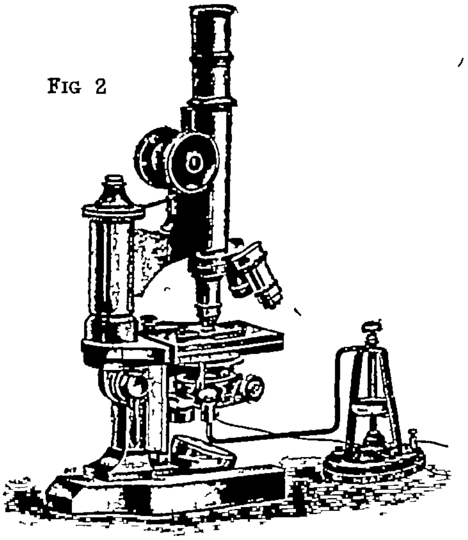
DARK GROUND illumination is invaluable to the early diagnosis of syphilis, but would probably have been more universally used if it had not required a comparatively strong source of illumination It can certainly be worked with such illuminants as an inverted mantle but the light and bull's eye have to be arranged very carefully and the average microscopist, more interested in rapid diagnosis than triumphs in optical skill has tended rather to neglect dark ground illumination where he could not command such an illuminant as an arc or a Nernst lamp To overcome this difficulty I was searching before the war commenced for a simple lamp which could be placed under the dark ground condenser and illuminate it without the intervention of a mirror At my request Mr N Clarke, of the Rochester Row Military Hospital, has worked out the mechanical details connected with the variable adjustment of the height of the lamp and the result is the arrangement illustrated. Although in its present form it will not demonstrate *Spirochæta pallida* satisfactorily with such paraboloidal condensers as the Zeiss, Reichert, Spencer lens, and Watson, it gives excellent results with dark ground condensers of the hemispherical type, such as the Leitz, Baker, and Swift. It is also a satisfactory illuminant for the examination of stained specimens

FIG 1



As shown (Fig 1), it consists of a small 4-volt bulb which is mounted on a stand, so that it can be raised or lowered by means of a milled wheel The lamp is run by a 4-volt accumulator or a dry cell, preferably the former It is set under the condenser (shown in Fig 2) and arranged so as to illuminate the centre of the field when the specimen is examined with a low objective The high powered objective is then turned on and the lamp raised or lowered by means of the milled wheel, so as to give the best illumination It may also be necessary to adjust the height of the condenser, lowering it very slightly to correct any haze The field is usually quite black and shows up spirochætes easily, it is not so dazzling as with stronger sources of illumination a point for which it may be preferred even by those who have electricity laid on and can use an arc lamp It was designed, however, for use where stronger forms of illumination than gas-light are not available

FIG 2



The lamp is made by Messrs Hearson's, incubator makers, 68, Willow Walk, Bermondsey, S E

HORMOTONE

The Dynamogenic Hormone Tonic for

ASTHENIC CONDITIONS.

HORMOTONE is proving a striking success in the treatment of many intractable cases It is primarily indicated in adrenal insufficiency, but is also useful in functional impotence, sterility due to ovarian insufficiency, amenorrhœa, dysmenorrhœa, and menopausal disorders

The Fatigue Syndrome Yields to Hormotone as to No Other Agent.

Dose: One or two tablets three times daily before meals

In Neurasthenia Associated with High Blood Pressure use **HORMOTONE WITHOUT PITUITARY.**

First Aid in Air Raids

THE dangers of air raids are known to all, and they are by no means small, even when no immediately fatal cases occur, but much of the risk is avoidable and is being avoided by the habit of taking immediate and adequate shelter It is not courage but only foolhardiness to court disaster in the open during the brief duration of an air raid, and such conduct endangers the lives of others, for it enhances the peril to the police and to the medical men, who are thus impeded in their work The dangers run by the whole community will be much lessened when every citizen makes a practice of taking as complete shelter as possible while the raid is progressing

The roll of fatalities in raids on the metropolis is statistically negligible when the population of Greater London is remembered, but prompt first aid to the wounded is of prime importance With a varying proportion of the injured the wounds will be of some severity, and, as recent records show, certain of these die not long after from the injuries they have received Many of those with wounds which lead to a fatal result might be saved if the bystanders knew what to do The authorities have arranged for medical and nursing aid to be brought soon to the injured, there is a corps of emergency surgeons who go on duty as soon as any notification of an air raid is received, and the hospitals are always ready to admit the wounded Yet all these arrangements, careful and elaborate though they may be, cannot be available until many minutes have elapsed after the infliction of the injury, and there is little doubt that lives could be saved if those near the injured could help immediately the need arises. A knowledge of first aid is now, indeed, widespread, but anyone who sees how the members of the public deal with a street accident must recognise that any kind of useful first aid is generally absent The knowledge acquired from classes on the subject is too often merely formal, and in the stress of an emergency yields to the aged and popular instinct to sit the sufferer up and give him brandy There are three conditions which more than any others call for immediate treatment One of these is hæmorrhage, and neglected it may rapidly prove fatal If it is in a limb it is a very simple matter to tie a handkerchief round the limb nearer the body and twist it tightly, a short stick, if available being used A victim in last Monday s raid is said to have saved his own life by so doing But simple as this course is it is not usually taken, and we think that medical men should take every opportunity of telling all their patients that to die of bleeding or to let a neighbour die of bleeding m[illegible] carelessness. If the bleeding is in the head or body this method cannot be used, and then the best treatment is firm digital pressure on the bleeding spot, but the uninitiated public cannot be expected to do good service in this way, save by giving every facility for the ministrations of more experienced persons Another danger arises from fire It is not at all rare in raids for the clothing to be set on fire, for some of the bombs are incendiary, and all should know that the speediest way to extinguish burning clothes is to wrap the sufferer in a coat, rug, or blanket, and so, by exclusion of the air, to put out the flames Nothing could be simpler, and yet how seldom is this method employed The third condition which calls for immediate treatment is impending asphyxiation. The fumes from the bombs may be the cause, or it may arise from the injuries received Be the cause what it may, the treatment required is, first, the removal from the mouth of any obstruction to breathing, and then the performance of artificial respiration Should no one present know how to carry this out, the simplest procedure is to dash cold water on to the patient's face, and this much knowledge should be in the possession of all, but we think the time has come when the heads of every household should understand the technique and rationale of artificial breathing

Our readers, of course, do not need these elementary instructions But when a little timely help is often of far greater value than aid which is delayed even for a quarter of an hour, we think that they might well impress upon the households which they visit, or their panel patients on suitable occasions, the value of acquiring such information. Everyone who can spare the time should learn first aid, and the aim of those who teach it should be not to endeavour to transform their pupils into surgeons by a few lectures and demonstrations, but to teach them to be ready to utilise those precious minutes which often elapse before a doctor can arrive on the scene Self possession and the application of the reasoning powers to the particular circumstances are essential to any knowledge of first aid, panic, whether violent or paralytic, is not only dangerous to the individual, but prevents him being of any service to his neighbours Every thinking citizen will subject himself to a course of mental as well as of physical drill to fit him for whatever may turn up in these strenuous times

Educational Hygiene

IN an address delivered last week before a meeting of teachers at Sheffield the President of the Board of Education noted the rapidly expanding interest taken in educational problems in every part of the kingdom The report, just appeared, of the Principal Medical Officer to the Board of Education is further evidence of this increasing interest In 1915 the staff of the School Medical Service had increased in number to some 1300 medical officers, 103 of whom were women and 88 whole time public

5789

servants, while nearly 1500 school nurses were at work, two thirds of them occupied during their whole time in the medical work of the schools At a time when doctors have been drafted from every possible source to meet the urgent claims of military service it was inevitable that these numbers should be substantially reduced, but it has nevertheless been generally admitted that no considerable economy could be made in the administration of the school medical service without serious risk of impairing the health of the present school child, and in so doing the future health of the nation s workers Recognising this by a stroke of genius the London County Council recently decided to reinstate its full staff of school doctors, so as to make it possible again to examine with care each entrant to school life Sir GEORGE NEWMAN records that during the year 1915–16 some five and a quarter million children were in average attendance at the public elementary schools of England and Wales, and that of this total nearly a million and a half were medically inspected during the year ending Dec 31st, 1916 Sad to say, the war was responsible for a decline of about 28 per cent in the number of children examined last year

Limitation of the medical staff proper has given occasion for an increasing coöperation among all agencies working for the physical betterment of school children Sir GEORGE NEWMAN alludes to the opportunities constantly arising in the teachers' life for considering the welfare of the children under their care Coöperation of teachers is at the present time a most important factor, and certain school medical officers have drawn up memoranda to assist head teachers in their districts in noting the indications for medical examination and treatment A change has been gradually coming over the duties of the school attendance officer The problem of school attendance has now become in the main a medical problem, other causes of truancy having practically vanished of recent years, and for the attendance officer there opens now the prospect of advising the mother of the school child on home treatment and the need for doctor or school clinic Only a woman health officer is fitted to do this, and she should no longer be expected to act as police court officer, nor should she bear the misleading appellation of sanitary inspector The sphere of usefulness for such officers, increased as it has been by war conditions, is not likely to diminish with the cessation of these special conditions In many districts voluntary children s care committees are in more or less active being, and it is in their effective work and coöperation with such agencies as the Invalid Children's Aid Association, the National Society for the Prevention of Cruelty to Children, the Children's Holiday Fund, and others that hope for the future lies The coördination of all such organisations to form an unbroken chain of medical supervision lasting from birth to adolescence is the ideal The neglect of systematic supervision has been largely responsible for the degree of physical disability to which medical recruiting boards have borne abundant testimony

Mr FISHER told us at Sheffield that one prominent lesson of the war is that the nation is rich enough and powerful enough to pay for anything that it really wants Judged by this standard the keenness of desire for an efficient school medical service might well be greater than in the year under review From 1913 to 1915 the yearly expenditure by local education authorities in respect of the work of the school medical service had increased from £286,000 to £411,000 In 1916 the increase was only 4 per cent on the previous year, although in fairness it should be added that during this year expenditure on education of mothers and infant welfare has largely increased The number of crêches set up by the Ministry of Munitions for the care of the children of married women employed in munition factories has now increased to 25, all of them drawing a grant of 75 per cent for initial provision and equipment, as well as a maintenance grant of 7*d* per head for each attendance, on the recommendation of the Board of Education An encouraging section of the report deals with open air education The open air school, Sir GEORGE NEWMAN writes, is a simple and economical way of applying a method of natural education to the susceptible body and mind of the children, and his remarks may be taken as a commentary on the proposal of the Education Bill, 1917, to found nursery schools The number of dull or backward children incapacitated by physical infirmity from deriving reasonable benefit from their schooling is estimated at 10 per cent, or a total of some 600,000 children, and for these is contemplated a combination of life in the open air with simple methods of tuition which might well be applied in the long run to all the children of tender age in the country The importance of the physical factors of ventilation, as distinct from mere chemical contamination of the air, long emphasised by Dr LEONARD HILL, has almost become a medical commonplace, but it has by no means obtained a firm hold in the practice of the elementary school. Dr HILL pleads with justice for ample open air school accommodation, not only for the debilitated and unhealthy children but for the normal child as well The gain will be seen not merely in the reduction in the cost of school buildings, a point doubtless appealing to local authorities, but in the reduced incidence of infectious disease and increased powers of resistance to them Miss MARGARET MCMILLAN S account[1] of her own adventure appears very opportunely In 1916 only 15 open air day schools were recognised by the regulations, affording accommodation for a mere handful of some 1000 scholars A few local authorities have provided in addition residential open air schools of recovery, but in these the accommodation does not amount to more than 400 or 500 places Mr FISHER S proposal for nursery schools will, if carried into effect, result in a gradual transformation of the infant department of the elementary school into a real open air nursery school, with an advantage to the youth of the nation which can hardly be exaggerated

"Ne quid nimis"

ATROPINE IN THE DIAGNOSIS OF TYPHOID INFECTIONS

We have received an interesting report, published by the Medical Research Committee of the National Health Insurance, giving the results of Captain H Fairley Marris's work on the effects of atropine upon the pulse rate of patients suffering from infections by the typhoid group of organisms—viz., *Bacillus typhosus* and *Bacillus paratyphosus A* and *B* A preliminary note has been published by Captain Marris,[1] and the present monograph gives a complete account of the test and of its results

The origin of the observations upon which the test is based was an investigation by Captain Marris of the bradycardia so commonly present in patients suffering from infections of the typhoid group In the course of this work he investigated the effect of atropine upon the slow pulse of these patients, giving a dose which in patients suffering from other conditions would cause a considerable increase in rate He found that in those with typhoid or paratyphoid fevers the pulse failed to respond to atropine by any definite increase in rate He also found that even with doses of 1/33 of a grain there were much less dryness of the mouth and dilatation of the pupil than would be produced in healthy persons by this dose In using this test Captain Marris has concentrated his attention upon the pulse-rate, owing to the fact that it is capable of exact measurement and therefore offers a mathematical basis for his test He satisfied himself after careful personal observations upon 200 suspected cases of these diseases that the atropine reaction could be employed for purposes of diagnosis, though unfortunately many of his records were destroyed in a fire occurring at the hospital in which they were carried out The routine method he now employs is to apply the test with the patient in the horizontal position and at complete rest *throughout*, and he recommends that it should not be done until at least an hour after the last meal The pulse is counted minute by minute till it is found to be steady, and usually ten minutes are recorded A dose of 1/33 grain of atropine sulphate is injected hypodermically, as a rule over the region of the triceps muscle After a period of 25 minutes the pulse is once more counted, minute by minute until it is clear that any rise which may have resulted from the injection has begun to pass off, for which purpose 15 or 20 minutes may be necessary The means of the readings before and of the readings at the maximum of the reaction after the atropine are compared, and if the difference between the two is 14 beats or less the test is regarded as positive and as indicating that the malady is one of the enteric group If a positive reaction occurs within the first 14 days of the disease the diagnosis may be regarded as established while if three negative reactions occur within the first fortnight the diagnosis of a typhoid or paratyphoid infection may be excluded with a considerable degree of certainty Cases admitted after the fourteenth day often give positive reactions but negative results after this period are often unreliable

In appraising the value of his reaction Captain Marris is careful to point out that his observations have been made upon members of the Expeditionary Force in France—that is, upon patients under unusual environment, and with their conditions modified by inoculation He indicates the need for investigation of this *reaction* in civilian patients before his results can be regarded as equally applicable to them In a series of his own cases 104 positive results were obtained in 111 first tests, and the test gave a correct report in 94 per cent. of the cases Captain Marris has investigated, as far as possible, certain other aspects of the atropine reaction in his research into its clinical value In six carriers of these infections he found in every case a negative result with the atropine test After inoculation with typhoid and paratyphoid vaccines in persons previously uninoculated, he obtained a positive result within two or three days, while previous to inoculation the reaction was negative It would appear that the reaction is of short duration, though this point requires further investigation, owing to the small number of cases so far examined Captain Marris gives certain reservations in regard to his test in addition to the one already referred to as to the value of negative reactions after the fourteenth day, thus he would be cautious in interpreting it in patients of 50 or over, especially in arterio sclerotic subjects Again, in patients with a pulse rate of 100 or over the conclusion from the test must be made with some caution If the response to atropine is negligible or the rate is lowered it may be regarded as positive, if, however, there is an increase of 8 or 10 beats per minute the test should be repeated In very severe cases it would appear that a negative reaction may occur Captain Marris concludes with some interesting suggestions as to the mechanism of the test, from which it would appear that he has supplied a convenient and easy test just when it was needed, as the problems of serological diagnosis have been complicated by protective inoculation It is to be hoped that his interesting monograph will be widely read and that it will stimulate research into this reaction in civilian patients and possibly lead to the discovery of similar reactions in other diseases

SACRO-ILIAC STRAIN

Professor William S Baer has called attention in the Bulletin of the Johns Hopkins Hospital to a lesion which the general practitioner often sees but fails to recognise, because it has been described only in recent years, mainly by American orthopædic surgeons Many have no doubt been wearied and even annoyed by patients who complain of pain—continuous and at times severe—in the small of the back or down the thigh It is attributed to rheumatism, sciatica, lumbago, pelvic disease, and other causes, and may defy the efforts of the general practitioner and the gynæcologist Many of these constant backaches—be they mild or severe, acute or chronic—are due to sprain or strain of the sacro iliac joint The term in use, sacro iliac synchondrosis, is a misnomer Recent investigations show that a true joint is present The articulating surfaces of the sacrum and ilium are covered by cartilage, and this by a thin layer of synovial membrane The motion allowed is small, owing to the configuration of the joint surfaces and the tightness of the ligaments The amount varies under different conditions and is greatest at the time of parturition, when it plays an important rôle in the mechanism of labour The strain on the joint is great, carrying as it does the trunk and upper limbs When the angle at which the joint is placed and the weight carried are considered, it is not surprising that strain is common This takes two forms according as the sacrum swings backward or forward on the axis of its third segment The former is the more important because of the severity of the symptoms It may be due to difficult labour direct injury such as a blow, or indirect injury in the form of severe muscular strain The pain may be so slight as to be merely a lumbar or gluteal ache on one side or so severe as to prevent walking and even lying down The sciatic nerve passes down directly in front of the sacro iliac joint, and according to the part pulled upon—sciatic, lesser sciatic, or servants, while nearly 1500 school nurses were at work, two thirds of them occupied during their whole time in the medical work of the schools At a time when doctors have been drafted from every possible source to meet the urgent claims of military service it was inevitable that these numbers should be substantially reduced, but it has nevertheless been generally admitted that no considerable economy could be made in the administration of the school medical service without serious risk of impairing the health of the present school child, and in so doing the future health of the nation s workers Recognising this by a stroke of genius the London County Council recently decided to reinstate its full staff of school doctors, so as to make it possible again to examine with care each entrant to school life Sir GEORGE NEWMAN records that during the year 1915–16 some five and a quarter million children were in average attendance at the public elementary schools of England and Wales, and that of this total nearly a million and a half were medically inspected during the year ending Dec 31st, 1916 Sad to say, the war was responsible for a decline of about 28 per cent in the number of children examined last year

"Ne quid nimis."

ATROPINE IN THE DIAGNOSIS OF TYPHOID INFECTIONS

WE have received an interesting report, published by the Medical Research Committee of the National Health Insurance, giving the results of Captain H. Fairley Marris's work on the effects of atropine upon the pulse rate of patients suffering from infections by the typhoid group of organisms—viz., *Bacillus typhosus* and *Bacillus paratyphosus A* and *B*. A preliminary note has been published by Captain Marris,[1] and the present monograph gives a complete account of the test and of its results.

The origin of the observations upon which the test is based was an investigation by Captain Marris of the bradycardia so commonly present in patients suffering from infections of the typhoid group. In the course of this work he investigated the effect of atropine upon the slow pulse of these patients, giving a dose which in patients suffering from other conditions would cause a considerable increase in rate. He found that in those with typhoid or paratyphoid fevers the pulse failed to respond to atropine by any definite increase in rate. He also found that even with doses of 1/33 of a grain there were much less dryness of the mouth and dilatation of the pupil than would be produced in healthy persons by this dose. In using this test Captain Marris has concentrated his attention upon the pulse-rate, owing to the fact that it is capable of exact measurement and therefore offers a mathematical basis for his test. He satisfied himself after careful personal observations upon 200 suspected cases of these diseases that the atropine reaction could be employed for purposes of diagnosis, though unfortunately many of his records were destroyed in a fire occurring at the hospital in which they were carried out. The routine method he now employs is to apply the test with the patient in the horizontal position and at complete rest throughout and he recommends that it should not be done until at least an hour after the last meal. The pulse is counted minute by minute till it is found to be steady, and usually ten minutes are recorded. A dose of 1/33 grain of atropine sulphate is injected hypodermically, as a rule over the region of the triceps muscle. After a period of 25 minutes the pulse is once more counted, minute by minute until it is clear that any rise which may have resulted from the injection has begun to pass off, for which purpose 15 or 20 minutes may be necessary. The means of the readings before and of the readings at the maximum of the reaction after the atropine are compared, and if the difference between the two is 14 beats or less the test is regarded as positive and as indicating that the malady is one of the enteric group. If a positive reaction occurs within the first 14 days of the disease the diagnosis may be regarded as established, while if three negative reactions occur within the first fortnight the diagnosis of a typhoid or paratyphoid infection may be excluded with a considerable degree of certainty. Cases admitted after the fourteenth day often give positive reactions, but negative results after this period are often unreliable.

In appraising the value of his reaction Captain Marris is careful to point out that his observations have been made upon members of the Expeditionary Force in France—that is, upon patients under unusual environment, and with their conditions modified by inoculation. He indicates the need for investigation of this reaction in civilian patients before his results can be regarded as equally applicable to them. In a series of his own cases 104 positive results were obtained in 111 first tests, and the test gave a correct report in 94 per cent of the cases. Captain Marris has investigated, as far as possible, certain other aspects of the atropine reaction in his research into its clinical value. In six carriers of these infections he found in every case a negative result with the atropine test. After inoculation with typhoid and paratyphoid vaccines in persons previously uninoculated, he obtained a positive result within two or three days, while previous to inoculation the reaction was negative. It would appear that the reaction is of short duration, though this point requires further investigation, owing to the small number of cases so far examined. Captain Marris gives certain reservations in regard to his test in addition to the one already referred to as to the value of negative reactions after the fourteenth day; thus he would be cautious in interpreting it in patients of 50 or over, especially in arterio sclerotic subjects. Again, in patients with a pulse rate of 100 or over the conclusion from the test must be made with some caution. If the response to atropine is negligible or the rate is lowered it may be regarded as positive; if, however, there is an increase of 8 or 10 beats per minute the test should be repeated. In very severe cases it would appear that a negative reaction may occur. Captain Marris concludes with some interesting suggestions as to the mechanism of the test, from which it would appear that he has supplied a convenient and easy test just when it was needed, as the problems of serological diagnosis have been complicated by protective inoculation. It is to be hoped that his interesting monograph will be widely read and that it will stimulate research into this reaction in civilian patients and possibly lead to the discovery of similar reactions in other diseases.

SACRO-ILIAC STRAIN

Professor William S. Baer has called attention in the Bulletin of the Johns Hopkins Hospital to a lesion which the general practitioner often sees but fails to recognise, because it has been described only in recent years, mainly by American orthopædic surgeons. Many have no doubt been wearied and even annoyed by patients who complain of pain—continuous and at times severe—in the small of the back or down the thigh. It is attributed to rheumatism, sciatica, lumbago, pelvic disease, and other causes, and may defy the efforts of the general practitioner and the gynæcologist. Many of these constant backaches—be they mild or severe, acute or chronic—are due to sprain or strain of the sacro-iliac joint. The term in use, sacro iliac synchondrosis, is a misnomer. Recent investigations show that a true joint is present. The articulating surfaces of the sacrum and ilium are covered by cartilage, and this by a thin layer of synovial membrane. The motion allowed is small, owing to the configuration of the joint surfaces and the tightness of the ligaments. The amount varies under different conditions and is greatest at the time of parturition, when it plays an important rôle in the mechanism of labour. The strain on the joint is great, carrying as it does the trunk and upper limbs. When the angle at which the joint is placed and the weight carried are considered, it is not surprising that strain is common. This takes two forms, according as the sacrum swings backward or forward on the axis of its third segment. The former is the more important because of the severity of the symptoms. It may be due to difficult labour, direct injury such as a blow, or indirect injury in the form of severe muscular strain. The pain may be so slight as to be merely a lumbar or gluteal ache on one side or so severe as to prevent walking and even lying down. The sciatic nerve passes down directly in front of the sacro iliac joint, and according to the part pulled upon—sciatic, lesser sciatic, or sacral nerves—the pain is referred along the corresponding branches In most cases pain is produced on pressure over the joint Professor Baer finds also that pain is invariably present over what he calls "the sacro iliac point," a point "just to the side of and just below the umbilicus" This point is so often mistaken for McBurney's that many operations for appendicitis have been erroneously performed Another sign is the flat back or obliteration of the lumbar curve, due to tilting of the upper part of the sacrum backwards In unilateral cases there is generally deviation of the spine to the side opposite to the affected joint Kernig's sign is positive on the affected side, owing to spasm of the hamstring muscles, and its elicitation produces pain in the joint Treatment is simple and gives most satisfactory results In acute but mild cases great relief is afforded by strongly compressing the buttocks and applying strips of plaster across them from trochanter to trochanter In more chronic cases a belt encircling the pelvis must be worn In women the corset may be used as a support for a webbing pelvic belt, or a pad which presses on the sacrum may be incorporated into the corset In cases which resist these mild measures and in severe cases manipulation must be performed under anæsthesia The fully extended lower limb is flexed on the abdomen, causing the contracted hamstrings to pull on the ischial tuberosity and drag the top of the ilium backward to meet the sacrum This procedure is carried on until the hamstrings are thoroughly relaxed It will now be found that the normal lumbar curve has reappeared The position is maintained by a plaster splint extending from the nipple to the knee After ten days this is removed and a pelvic belt substituted Forward tilting of the sacrum is of different causation and occurs in girls who have outgrown their strength and in cases of visceroptosis The back is hollow, and the main principle of treatment is to relieve the weakened abdominal muscles by a suitable corset Massage and exercises should also be used

A STATE-AIDED MIDWIFERY SERVICE IN ENGLAND AND WALES

THE memorandum put forward by the Association for Promoting the Training and Supply of Midwives, which we briefly noticed in THE LANCET of Sept 8th, continues to claim attention, and a correspondent comments on some of the main aspects of the problem of a State aided midwifery service The greatest need in maternity and infant welfare is to secure an efficient service in all parts of the country, so that the women in the poorest and often most congested districts shall not be left with inefficient attendance At the present time it is left to chance or to private beneficence or to various associations to make the best of the existing deficiencies A relatively small proportion of the women training as midwives ever practise, and the reason of this is that in present conditions it is very difficult to make an adequate livelihood, the fees they obtain from patients being too small It is suggested that a proper fee for a midwife attending a confinement should be at least 20s to 25s, according to the services rendered The requisite sum required for providing these fees should be paid by the Exchequer and not be left to be provided by local rates It is not considered desirable that attempts should be made to recover from the patient any charge for the services rendered under the new scheme, and in any event the fee of the midwife should not be dependent on the sum recovered from the patient For such a scheme to be effective it is necessary that the money should be disbursed by the same body as is responsible for the inspection of midwives under the Midwives Act It is suggested that the county borough council and the county council should administer these services, and the scheme must be conditional on great improvements being effected in the inspection of midwives in all parts of the country It is further proposed that the guaranteed fee should be available also for any doctor who undertakes to give and does actually give the proper attendance and services at the confinement In the event of midwives being compelled to summon a doctor to a case the fees should be payable out of the same fund The whole scheme would entail an estimated expenditure of nearly £100,000 per annum This sum would enable an efficient midwifery service to be given to every confinement in England and Wales in which the income is below the suggested £160 limit The proposal that the conditions could be met by an increase in the amount of the maternity benefits or by the allowance of a cash payment to the mothers is not approved because this does not ensure the provision of efficient services. The scheme, as it runs, would, however, secure that the whole of the money allowed by the Exchequer is expended directly on the provision of services that immediately affect the welfare of the mother and her infant No one will deny that adequate midwifery attendance is essential to the well being of the community, and the fact that some 70–75 per cent of all births are attended by midwives renders this matter one of national importance At the present time there is still a large number of untrained midwives on the Register who were in practice before the passing of the Midwives Act, but it is disappointing to find how small a number of the women who qualify as midwives actually enter into practice. The reason is the very simple one already called attention to—viz, that an adequate living cannot be made in present conditions The work is very arduous and badly paid In these circumstances the proposals advocated by Dr. E W Hope in the above scheme have much to recommend them, and we are of opinion, if the poor throughout the country, and particularly in the poorer districts, are ever to secure a really reliable midwifery service, that some such State aided scheme is a necessity

LUMBAR PUNCTURE AS A CURE FOR CERTAIN FORMS OF IDIOPATHIC HEADACHE

Dr G Mingazzini, professor of neurology in the University of Rome, has published 47 cases of persistent headache treated by lumbar puncture[1] Before Quincke introduced his method of lumbar puncture cases had been recorded which showed that increase in the pressure of the cerebro spinal fluid was the cause of inveterate headache, relief having followed an abundant discharge from the nose or ear, while Oppenheim noticed in a patient suffering from such attacks an optic neuritis with paracentral scotoma It seems therefore probable that there are oscillations in the quantity of blood and cerebral blood pressure in relation with the functions of the brain Physiologically such varia tions are impeded by the hardness of the skull, and especially by the cerebro spinal fluid, and there is therefore a reciprocity between the amount of blood and that of the fluid which causes variations of pressure in the latter The favourable results obtained from lumbar puncture by Salmon in the treatment of intense headache accompanied by disturbance of vision induced Professor Mingazzini to apply this method to those forms of permanent headache which are so frequent, especially in young women

---

[1] Il Policlinico Medical Section July 1st, 1917

The patients, six men and 41 women, were kept under observation for several months, some even for two or three years They were all selected, uncomplicated cases, care being taken to eliminate any suspected of syphilis or tubercle, chronic nephritis, or intoxication by tobacco or alcohol, epilepsy or incipient tumour, a searching examination of the fundus oculi being insisted upon in every instance The results of analysis of the fluid were invariably normal, all trace of globulin being absent, lymphocytes were either not present or did not exceed 2-3 while the albumin was in normal quantity as shown by Nissl's test In almost all the patients there was a distinct increase of the headache after the puncture sometimes lasting 8-10 days, rarely the pain disappeared immediately after puncture, while in one case only was there first a remission and then an exacerbation The results of the puncture were not always the same a definite cure was obtained in 24 about half the cases, a distinct improvement in 15 in whom the pain was so mitigated as to be more than bearable or returned after a long interval In 8 cases no benefit was obtained The result, favourable or otherwise, did not seem to depend on the age of the patient at the time, thus in one woman, aged 60 years, who had been subject from her youth to frequent attacks of headache, which for about six months had become of daily occurrence a definite cure was obtained from a single puncture, while in another patient of 22 years who had suffered for two years from headache after typhoid fever, no benefit resulted In the unbenefited cases the pressure of the cerebro-spinal fluid was normal or low, whereas in those where there was improvement it was always high indicating that increased pressure must be considered as one of the indubitable factors of the complaint There seemed to be no connexion however, between the quantity of fluid drawn off and the result obtained, in fact, in several patients who got no relief as much as 15 to 30 c c were drawn off, whereas in some who were relieved or cured 10 or even 5 c c were sufficient

It might be thought that in cases where there was merely some improvement a complete cure would be obtained from a second puncture, but this only rarely happens, and some cases have derived no benefit even from repeated puncture The reason for these different results is by no means clear, but, as a general rule, it may be stated that when the first attacks have begun early in life and the headache has become permanent later on without appreciable cause, the result of puncture has been a cure, or at least an improvement No improvement, on the contrary, takes place in women in whom the headache had either been permanent from the beginning, or had commenced by attacks after the age of 20, and become permanent from debilitating causes, such as suckling or long illness, or else was associated with other neuroses, such as neuralgia of the fifth nerve polio encephalitis and epilepsy Those cases which improved after puncture had generally suffered from permanent headache for a few months, whereas in patients in whom no benefit resulted the headache had been permanent for more than a year Hence a permanent headache of long duration seems to be an element unfavourable for cure by puncture, but the changing of the headache from a paroxysmal to a permanent form, a commencement in the second decade of life without appreciable cause, and a duration of permanent headache for less than a year, represent elements favourable to the success of lumbar puncture

THE BIOLOGICAL ASPECTS OF WARFARE.

The Checks to the Operation of Might

IT will be observed that the checks on the operation of egoistic might which we have already considered are purely intra communal, their sole object being the integrity of the community In the earlier phases of human society they took no part in regulating the relations between separate communities—between family and family or between tribe and tribe The concern of each unit was its own welfare alone It did not in the least trouble itself about the welfare of other communities Consequently the principles which regulated the conduct of the members of any one community among themselves in no way governed their conduct towards other communities The code of morality within the community did not obtain between individual communities Rather was there a tendency for separate communities to regard one another with suspicion and animosity, so that incessant inter tribal warfare may be said to have been the normal condition during the tribal phase of man's history The more one tribe could injure its neighbours by murder, pillage, and the like the more did it aggrandise itself, just as the status of the young brave was raised as the number of scalps he could display increased In short, the sanction of conduct obtaining between separate communities was just that of might pure and simple But with the further development of society—with the establishment of nations having commercial relations with one another—agreements of some sort had to be entered into between them, and these international obligations have become more and more binding as civilisation has advanced.

Now it might be thought that with the growth of commercialism, and the increasingly intimate social relations between separate states rendered possible by the ever-growing facilities of intercourse and transit, those checks to the operation of the might sanction which obtain within, and secure the cohesion of individual states would in like manner gradually come to unite the nations of the world in one all embracing commonwealth, and that just as within the properly ordered state conduct is guided and conflicting interests—personal, social, political, religious—reconciled, on lines of justice and common sense, so also could, and should, international conduct be governed and international disputes be adjusted But this devoutly to-be-wished for consummation is not yet We have recently seen how a nation may in its dealings with other nations cast aside all moral restraints and revert to the same sanction of might as obtained between the most primitive human communities

There could be no greater contrast than that between the ethical standard prevailing within a State and that obtaining between States at war with one another In the one case the motto is, 'Let justice be done though the heavens fall', in the other justice is cast to the winds and the issues are to be decided by might alone In the one case so high is the value set on life that every opportunity is afforded even to the most atrocious murderer to prove that he is innocent, in the other wholesale slaughter by the most terrible means which the mind of man can devise is sanctioned. In the one case the sanctity of private property and of compacts is rigorously upheld by all the might and majesty of the law, in the other compacts are dishonoured and property destroyed or confiscated to the value of untold millions on the sole ground of military necessity All this is strangely primitive When the citizens of a well ordered State have a dispute over conflicting interests, private or social, they appeal to justice, and were anyone to suggest that the issue should be decided by personal combat his sanity would be suspected, but when a dispute arises between two nations and they fail to adjust it by argument it but rarely happens that they mutually agree—especially if the one be more powerful than the other—to submit to arbitration, they appeal instead—they revert—to the age old sanction of might.

---

* Article I and the first part of Article II were published in THE LANCET of Sept. 15th (p 433) and Sept 22nd (p 4[illegible]) respectively

The Influence of Warfare in Moulding the Individual

In considering the effects of warfare on mankind we must distinguish between its educative effects, i e , its influence in moulding the individual, and its racial effects, i e , its influence in moulding the race As regards the latter, I have already endeavoured to show that, while primitive intertribal warfare operated eugenically by favouring a survival of superior types, modern warfare operates dysgenically by promoting the survival of inferior types But while modern warfare is thus *racially* harmful, *individually* warfare has always had some educational value, and it would be idle to shut our eyes to the fact It is remarkable that among primitive communities those which cultivate warfare are generally superior to those leading peaceful lives It may be argued that they become warlike because they are superior rather than the reverse Facts, however, tend to show that whether a community is warlike or peaceful depends mainly upon the conditions under which it lives , thus the nomadic career of the hunter and herdsman is favourable to the warlike spirit, while the life of "stationary" (as distinguished from "migratory") agriculture tends to be peaceful

There can be no doubt that military training has a beneficial influence, physical and mental, in moulding the individual Its good effect physically is shown in the rapid improvement in the physique of recruits after enlistment (At the outbreak of the present war there were far too many contracted chests and round shoulders in this country) Its value in the moulding of character is no less decided , above all, it teaches discipline and respect for authority, both of which are in danger of neglect in democratic communities It would be difficult to exaggerate the importance of discipline it is a prime essential to good citizenship, and it is as needful to the one sex as the other Every boy and every girl should from an early age come under its rigorous influence and be made to realise not only that it is an essential to right living, but also to individual happiness and success in life , and there is nothing better calculated to inculcate discipline than military training This, or something equivalent to it, should begin in early school life

So much for the good that can be got from training for war What about war itself? While realising that man has evolved through slaughter, and that every step in his long upward path has been stained with blood, I must confess that modern warfare seems to me as inane as it is horrible This wholesale slaughter and mutilation of one set of men by another set of men who have no personal quarrel with one another, who are not even personally known to one another, and who under different circumstances might have been knit together in closest fellowship, has for me no bright side This driving of thousands upon thousands of a nation's picked manhood to the shambles, this wanton carnage, to say nothing of the loss of productive energy and the colossal destruction of wealth, is, one feels instinctively, wrong the horror is only equalled by the inanity of it

But though actual war is detestable yet it must be confessed that indirectly it serves a useful purpose in that the fear of it leads a nation to exercise itself in the virile pursuit of arms and to hold itself in readiness to meet an enemy, while actual war rouses the community to put forth supreme efforts, and this striving to overcome a threatened or actual danger works beneficially and leads to the development of latent possibilities in a manner undreamt of in the easy going times of peace

Nothing but the call of actual war could have aroused our country to accomplish what it has accomplished since the July of 1914 What other impelling force could have induced us to increase our national expenditure tenfold, to liberate vast stores of unused energy, to transform the whole economic life of the people, to sacrifice by tens of thousands the flower of our manhood, as has been done since the declaration of the war? All which goes to show how great things a nation can accomplish once the necessary stimulus is forthcoming If only some equally effective stimulus could be found in times of peace, one which should impel to similar energetic action, not for the purpose of slaughter and destruction, but for the common good! What might not be accomplished if all the energy and ingenuity and self sacrifice which we have devoted to the prosecution of this war had been directed to the clearing out of the slums of our cities and to the providing for the toiling millions healthy, well appointed, and beautiful homes Our present experience should serve to bring forcibly before us the fact that we have it in our power to do all this and much more All that is needed is the proper organisation and distribution of our activities—*and the adequate stimulus* But how to get the stimulus is the difficulty I fear that nothing but a great external danger such as we are now facing is capable of supplying it Theoretically a great religious revival might suffice, but it would have to be one which concerned itself not so much with the attainment of a possible heaven in another world as with the removal of some of the evils suggestive of another place in this one

Strange as it may seem, and contrary as it may be to our predilections and *a priori* conceptions, the condition of peaceful ease in which we picture the lion lying down with the lamb is, from nature's point of view, far from the ideal. A community long lulled in a state of blissful ease is bound to deteriorate for all healthful life implies struggle Man needs to be roused from the apathy into which he so easily slips by difficulties to overcome, and there is no more arousing stimulus than the apprehension of danger

Few will deny that when the present world war burst upon us we had as a nation grown lax and inert through long years of ease and luxury, and that whatever may be said of the ultimate effect of the war on the other belligerents, the people of these islands and of the British Empire as a whole will be greatly benefited by it For not only has it tightened the bonds which unite the units of the Empire, but it has awakened undreamt of stores of dormant activity, and I go as far as to believe that the greater the difficulties we may still have to contend with—the tighter the corner in which we may find ourselves, the more we may be compelled to fight with our backs to the wall—the better will it be for us individually and for the Empire at large , for it is only through struggle, fierce and sustained, that an individual or a nation can realise itself to the full Struggle has been a necessary factor in evolution. It is the normal condition of every living thing save those degraded parasites which inhabit the interior of their host and pay the penalty of their parasitism by a corresponding degradation in structure and function , for it is a primal law of nature that once the need for struggle is removed degeneration sets in Hence one of the great social problems confronting man in the future will be how, without having recourse to war with all its horrors to counteract the enervating and degenerating effects of the ease and luxury which tend to be shared by a considerable section of every prosperous community In the perfect State the conditions would be such as to render such enervation impossible Every able-bodied person would be compelled to pull his full weight in the ship of State—to play his part in that healthful struggle which is essential to adequate development Pure parasitism which prevails all too widely among us would be debarred save in the case of the diseased and decrepid To sanction it is unjust to the individual, though he may not know it, and unjust to the State (In insisting upon struggle as essential to development individual and national, I do not, of course, mean that it should be so severe as to be paralysing No one would contend, e g that conditions of abject poverty can have any other than evil results)

If I am asked how a nation, once peace and prosperity are secured to it, is to be kept engaged in bracing struggle and prevented from lapsing into enervating ease, I reply that I have no panacea This desirable end can only come through enlightenment But while so many evils to be set right still remain within the body politic, while so many social questions of the gravest urgency press increasingly upon us while all Europe has to be rebuilded and its new world relations to be readjusted it is safe to say that it will be long years before we shall be in any danger of relapsing into dreamful ease and before that time comes the enlightenment may have come also Moreover

> Man is not man as yet.
> When all mankind alike is perfected
> Equal in full blown powers—then not till then
> begins man s general infancy

Means of Preventing Warfare

Whether the nations of the world will ever attain to sufficient wisdom to abandon warfare I forbear to prophesy One cannot but hope that with advancing knowledge and clearer vision war will tend to die out and that just as we in this country, after centuries of internecine fighting were finally welded into a united people, so all the nations of the earth will some day be united into one great commonwealth. We are living in great times. Vast regions of the world are being opened up and developed with stupendous zeal, the exuberant output of inventions, such as the telephone the automobile, the flying machine, and labour saving machinery of all kinds, is profoundly modifying the conditions of life, intercourse between nations is becoming more and more intimate, added to which men are gaining an ever deeper insight into the laws of life, the elemental facts of evolution, of heredity and of social science are beginning to make serious appeal to men's minds and must before long be accepted as axiomatic truths pregnant with meaning as regards human welfare. The time is not far distant when children will be taught these truths as they were once taught their catechism, so that they will become part and parcel of the common mental equipment, and when this stage of general enlightenment is reached nations, it may be hoped, will find other ways of settling their disputes than by an appeal to the barbaric sanction of might.

When the unhappy Malvolio complained of the darkness of his cell, the fool's taunt was, "There is no darkness but ignorance." It was Malvolio's entire ignorance of the true situation which led him to think that his mistress had lost her heart to him, and in like manner it was the darkness of ignorance which is responsible for the present European cataclysm, ignorance alike of the elemental principles of sociology and current European politics. Does anyone for one moment suppose that the masses of the Central Empires would have entered upon the present struggle so light-heartedly if they had understood the actual situation as the author of "J'Accuse" e.g. understands it? Or if they had realised that hundreds of thousands of their numbers were to be slaughtered and broken without any resultant advantage to the survivors? Again, was it not ignorance—tragic ignorance—on the part of their rulers which allowed them to force on the war? They miscalculated they displayed stupidity—they lacked *enlightenment*. Had they *known* the forces they were stirring up against themselves we may be quite sure they would not have been guilty of what must ever rank as one of the greatest crimes in history.

A factor which we may reasonably hope will tend to make wars less frequent is the growth of democracy. The trend of political development among the most enlightened nations is towards a moderate sane Socialism—a system of government which while giving individualism fair scope, shall tend to equalise the present social inequalities. The political power of the masses will then steadily increase, and provided they be properly educated they may safely be trusted to use their power wisely. And when the informed masses of the different nations are brought together through accredited leaders and are thus enabled to act coördinately they, realising how much they have to lose and how little to gain by warring against one another may be expected to insist that international disputes shall be adjusted on lines of justice and common sense.

Commercial competition constitutes an important cause of warfare, naturally each nation tends to do the best for itself commercially. Hence has arisen the pernicious system of tariffs by which each nation strives to encourage its own industries at the expense of those of other nations and this artificial bolstering up of home industries sets artificial boundaries between the nations and is a perennial source of jealousies frictions and quarrels. An infinite benefit would be conferred upon the world at large by a removal of these artificial barriers and by the adoption of free trade all round. Not only would this do away with the immense amount of delay and inconvenience necessitated by the collection of duties, not only would it facilitate international intercourse and liberate armies of officials engaged in unproductive labour for employment profitable to the State but most important of all it would remove what is perhaps the chief cause of warfare.

The establishment of a United States of Europe trading among themselves as do the United States of America without any harassing restrictions has surely been the dream of everyone who has thought seriously over the social future of the peoples of Europe. Under such a system each State should as far as possible be constituted with due regard to race history and popular vote, each should be allowed to govern itself in its own way without any unwise interruption of historical continuity or any undue breaking away from tradition and no State should arrogate to itself precedence over any other. The fighting force of each State should be no larger than would suffice for the maintenance of internal order, and all plant for the manufacture of weapons other than those needful for this purpose should be scrapped. There would thus be an end of artillery—light and heavy—quick firing guns, bombs, mines, and the like. The sole firearm remaining would be the rifle which being used for sport could not well be discarded. Needless to say that with these restrictions aerial and submarine warfare would die a natural death while warfare by sea and land, if it did occur, would be infinitely less disastrous than at present—though quite as efficacious. (I may remark by the way that aerial warfare bids fair to eliminate all other forms. What naval or military base could withstand the bombardment of 50,000 aeroplanes? Only subterranean chambers are safe from serious aerial attack.) Any breach of the covenant by a State, or any dispute between one State and another, should be referred to a supreme tribunal constituted of delegates from each State.

I am aware, of course, that at the present time such a scheme is purely visionary it is but a dream yet it is one that we may well strive to make a reality.

Postscript

Considerations of space have prevented me from dealing with many aspects of my subject. One of these relates to fear. Is it not wonderful that so many millions of men are capable of mustering sufficient courage to face the terrors of modern warfare? Courage is an asset of inestimable value.

> Cowards die many times before their deaths
> The valiant never taste of death but once

We as medical men are familiar with the pathophobiac who pays us periodical visits in order to be assured that there is nothing the matter with him and of the man who smilingly meets a lingering death from cancer of the larynx. One of the unhappy effects of modern warfare is that it tends to preserve the timid at the expense of the brave, thus lowering the racial level of courage. The brave man seeks out danger, the timid man avoids it, and there are many ways of evading dangerous service and of minimising risks.

The liability to fear may be so great as to be pathological. One of this temperament is apt to become the victim of morbid fears—fears having no adequate objective cause. Claustrophobia is such a fear. I am led to refer to it here because the conditions of modern trench warfare are specially calculated to call it forth and also because Dr. W. H. R. Rivers has recently related an interesting case of this disease in the pages of this journal.[1] My interest in claustrophobia was roused many years ago by a family of claustrophobiacs, and since then I have had the opportunity of studying several cases.

Those who display a constitutional morbid tendency to fear—the congenital phobiacs as we may term them—constitute a definite class of psychasthenics. What particular form their fear, or fears, shall take depends very largely upon chance circumstances, but claustrophobia, like the fear of the dark and other instinctive fears, tends to be inherited as such as I have several times observed. This morbid fear appears to be an exaggeration of a normal instinct—the dread of capture or of anything which interferes with bodily freedom. It will be remembered that one of Lear's wicked daughters, in her endeavour to outbid her sisters for the father's goodwill could think of no more precious possessions than "eyesight *space*, and *liberty*."

In the family referred to the father, several of the children, and some of the grandchildren have displayed well marked claustrophobic tendencies and I have satisfied myself that in each case the fear has arisen independently and that mutual suggestion has played no part in the pathogenesis. One of the sons has not travelled for 30 years in a train, another son at the age of 50 suddenly developed panic while travelling in the Tube and has had to give up that mode of travelling.

I would take this opportunity of advancing two propositions bearing upon the pathogenesis and treatment of psychasthenia.

1. The essential feature of all the phobias met with in psychasthenia, and indeed, of all forms of genuine psychasthenia is a congenitally defective mental temperament—an abnormality in the realm of feeling tone. How far this depends upon defective cerebral organisation (e.g. of the paleo-thalamus the probable centre of feeling tone) or how

---

[1] THE LANCET 1917 ii p 237

far upon the composition of the blood plasma, need not now be considered

2 Mental temperament is inborn, and but little susceptible of being altered A person is born with a certain temperament for which he is no more responsible than for the shape of his nose, and this inborn temperament tends to remain fundamentally the same throughout life, resisting almost completely all attempts, educational or psycho-therapeutical, to modify it No doubt some of his emotional disposition can be modified by training—an artistic aptitude can be developed by constant exercise, a bad temper bettered by systematic control—yet the native temperament remains, fundamentally unchanged A person's temperament never in fact, undergoes a decided change except as the result of the normal cyclical changes, such as puberty and senility, or in consequence of disease, such as Graves's disease, myxœdema, or actual insanity We meet a man we have not seen for years, and when we come to speak to him it is as if we were carrying on a conversation of yesterday, so conscious are we of his unaltered temperament, and it is this which constitutes the essence of the man, or, as we say, his personality There are the same old gestures, the same old tricks of speech, the same old play of facial expression, all indicative of the same temperament Contact with the world, his successes, his failures, his troubles, have no doubt left their impress Youthful ardour may have been damped, the optimist may have lost some of his hopefulness, the shy man may have grown bolder, the genial man may have become somewhat soured, the cheery nature more subdued, but all such changes are on the surface only When we come to probe below the surface we shall find that the temperament remains fundamentally the same the very sensitive, the very shy, the very timid, the irrepressibly self confident, remain sensitive, shy, timid, self-confident to the end of the chapter

Now if the foregoing propositions are sound—if a congenitally morbid mental temperament constitutes the basis of classical psychasthenia, and if temperament is all but insusceptible of being changed—the limitations of psychotherapy in psychasthenia are apparent If we cannot alter feeling tone, strike at the foundation upon which the whole superstructure of psychasthenia is built up, we cannot cure the affection In my experience the congenital psychasthenic remains psychasthenic to the end. I am far from saying that psychic treatment is wholly useless for these patients Much can be done to establish a sane habit of thought and to discipline morbid feeling tone, even though this remains essentially the same

As to the legitimacy of the conclusions Dr Rivers draws from his case I am somewhat doubtful His patient, one judges from the description, appears to be a congenital psychasthenic with a bent towards claustrophobia. It is, of course, conceivable that but for the early claustrophobic incident the specific fear of closed spaces would never have displayed itself, but everything must have a beginning, and I judge that the experience with the dog happened to be the first opportunity for the display of the specific fear Thereafter it showed itself on several occasions, and I suggest that these later manifestations would have occurred even in the absence of the initial incident

My experience of claustrophobia leads me to doubt whether the mere resuscitation of a forgotten experience is capable of dispersing the fear May not the cure (?) in Dr Rivers's case be an instance of faith healing? Do we sufficiently realise the tremendous power of *absolute* belief? If we could convince a person that by jumping off the Monument in a particular way he would plane gently down and alight unhurt below, he would have no kind of hesitation in attempting the experiment Similarly, if we succeed in implanting the belief that the revival of a forgotten fearful experience will for ever prevent the recurrence of a similar fear, we shall go far to prevent its recurrence The crucial test would be to observe the effect of the revival without letting the patient know that a cure was expected from it

THE PHYSIOLOGICAL AND ANTISEPT PROPERTIES OF FLAVINE

To the Editor of THE LANCET

SIR,—The tone of Dr C H Browning's letter in y issue of Sept 15th is an unfortunate one It seems to more an expression of his wounded feelings than argume against my findings

He congratulates himself that in his second paper flavine, which appeared in the *British Medical Journal* July 21st last, he forestalled me in a number of my expe ments. In this matter he may certainly congratulate himse as my article was in the hands of the censorship authoriti weeks before his paper appeared His experiments, howeve were not carried far enough In connexion with the to power of flavine on the leucocytes, he still used as t maximum time of exposure two hours, which is altogeth too short to bring out the full toxic effect on the leucocyte just as it fails to show the maximum bactericidal power his first paper he found that flavine 1 in 500 was the highe dilution which in 20 minutes caused marked inhibition phagocytosis In his second paper he states that two hours flavine 1 in 10,000 had little effect on t phagocytic power I have found that in five hours flavi 1 in 256,000 gives marked inhibition of phagocytosis, whi in 24 hours the leucocytes are completely destroyed by 1 in 2,000,000 dilution

I have shown in my article that a 1 in 2000 dilution flavine completely inhibits emigration of the leucocyte However, in a septic wound treated with flavine 1 in 10 there is still a more or less purulent exudate This capable of two explanations either the *in vitro* experime does not represent what happens in the body or the flavi does not come into contact with the leucocytes in t walls of the wound in sufficient strength to prevent the emigration As we shall see the latter is the more like explanation

Experiments cited in my paper show that the purule discharges from a wound are very potent in "quenching flavine The bared surfaces of the wound also have a gre affinity for flavine. The following observation illustrate this point A patient had a cup-shaped wound in the fro of his leg following a fracture of the tibia. This depressio was about 2 × 1, × 1 cm and held about 1½ c c. of fluid was lined with granulation tissue The hole was carefull swabbed out and washed with normal saline solution unti the washings were clear In the next two hours it had fo changes of flavine (1 in 1000) and then it was filled wit flavine (1 in 1000) which was allowed to remain for tw hours, after which it was removed The strength of th flavine removed as measured by the colour intensity wa 1 in 3500 We see, then, that the granulation tissue-wall of this wound extracted in two hours most of the flavi from the solution applied, and that even after the had been well dyed with four changes of 1 in 1000 flavi during the previous two hours

The same wound, immediately after I had removed the above mentioned two-hour sample of flavine, was filled with a fresh supply of flavine 1 in 1000 and left for 15 hours. A the end of that time the walls of the wound were covered with a mucous like coating which I take to be the same that the distinguished surgeon (name unknown) has commended as "coagulated lymph" On examination this appeared to consist almost entirely of disintegrated leucocytes, a finding quite in keeping with the test-tube experiments on the powerful leucocidal action of flavine

The original instructions sent out with flavine by the Medical Research Committee, and presumably drawn up b Dr Browning, stated that it might be employed in conjunction with any of the various techniques recently advocated in wound treatment In his second paper on flavine Dr Browning mentions that unsatisfactory results have followed the two-hourly flushing with flavine after the method of Carrel, and he recommends that it be applied on gauze and only the minimum of water should be introduced so that the discharges of the wound might not be unduly diluted, as the antiseptic acts better in a serous medium Here as elsewhere Dr Browning seems to assume that in a septic wound the discharge consists only of serum and bacteria In connexion with the application of flavine on gauze it is of some interest to note the quenching effect of ordinary surgical gauze on flavine A piece of gauze was taken measuring 11 × 9 centimetres, 16-ply thick, and weighing 5 grammes This was placed in a small dish and 20 c c of flavine 1 in 1000, was poured on The gauze was kneaded for a few seconds to distribute the fluid in its interstices and then 12 c c. of fluid was squeezed out The colour of this corresponded with a 1 in 5000 dilution of flavine The fluid was poured back on the gauze and left two hours, after which on being expressed, it gave a colour corresponding with flavine 1 in 10 000 A similar experiment was done with flavine 1 in 4000 (using the same weight of gauze and the same volume of fluid), and after being in contact with the gauze for five minutes the expressed fluid corresponded in colour to flavine 1 in 128 000 These observations show clearly that the gauze dressing has a very powerful affinity for flavine, and that if gauze is wetted with a solution of flavine and applied to a wound the concentration of the dye which comes out of the gauze is very much less than that which went in Another very simple method of demonstrating the great affinity of cotton tissues for flavine is to half fill a small test-tube with flavine 1 in 1000 and to press down slowly into it a tight-fitting cotton wool plug The first fluid which exudes above the cotton wool will have absolutely none of the yellow colour of flavine. It may be done also by packing tightly a little wool or gauze into a piece of glass tubing and allowing a 1 in 1000 solution of flavine to percolate through it. The first fluid which comes through will have no yellow colour Using this method, and packing a piece of gauze weighing 0 38 gm. into a tube of a calibre of 6 mm , from a solution of 1 in 1000 flavine 1 3 c c of colourless fluid percolated through before any trace of the yellow colour of flavine was noticed It may be that this action of gauze in reducing the effective concentration of flavine is the cause of the difference between the unsatisfactory results which have followed the application of flavine by irrigation after the method of Carrel and the more favourable results which have followed its application on gauze Dr Browning has stated that too frequent applications of flavine may lead to 'undesirable cumulative effects on the tissues locally," and in this way he explains the failure of flavine used by Carrel's method The absorptive action of the gauze would certainly seem to prevent this

Dr Browning states "It appeared to be a hard enough task to demand of an antiseptic that it should not be quenched in a serous medium,' and he appears to resent the suggestion that anything further should be asked of an antiseptic The production of an antiseptic the power of which is enhanced by serum is a very fine achievement, but in the case of flavine this seems to be more than counterbalanced by the ease with which the dye is absorbed by the walls of the wound, by the purulent discharges, and by the dressings

Dr Browning objects to my interpretation of the 'therapeutic coefficient' as a comparison of the toxicity of a substance to leucocytes with its toxicity to bacteria (acting in serum) Although there can be no doubt from the text of his original article that this was the sense in which he used the term, he insists that it should be applied only to the ratio between the concentration which inhibits phagocytosis by 50 per cent *acting for 20 minutes in 25 per cent serum* and the lethal concentration to bacteria *acting for 24 hours in 50 per cent serum* If the term is to be applied only in this limited sense then Browning's coefficient' would be an appropriate name, but 'therapeutic coefficient is altogether too ambitious and implies that the numeral arrived at has some real value in therapeutics

When I started working with flavine I hoped that I should be able to convince myself that at last we had a really efficient antiseptic for use in septic wounds and it was with great regret that I found my experimental results could lead me to no other conclusions than the unfavourable ones mentioned in my article

I am Sir, yours faithfully

ALEXANDER FLEMING

Sept [illegible]th 1917

PURULENT BRONCHITIS

ITS INFLUENZAL AND PNEUMOCOCCAL BACTERIOLOGY

To the Editor of THE LANCET

SIR,—I have read with considerable interest the article as above entitled by Captain Adolphe Abrahams Captain N F Hallows, Dr J W H Eyre, and Major H French in your issue of Sept 8th, nevertheless, in fairness to myself, I should like to have the opportunity of pointing out that their observations contain little that is new and not contained in my "Bacterial Diseases of Respiration"[1] Therein I pointed out (1) how atypical and unlike anything described in the standard text-books of medicine are the majority of cases of bacterial infections of the lower respiratory tract, and (2) how rare it was in my experience for cases of lobar pneumonia to have a sudden onset, or occur, as it were, spontaneously, but that, on the other hand, they were either due to an awakening of a dormant focus of infection in the lung, or to the rapid extension into the chest of an acute nasal or tracheal catarrh, especially when the *B influenzæ* is associated with the pneumococcus (pp 103, 104) I also pointed out (p 105) that

> The pneumonia supervening on an attack of so-called 'influenza this latter being much more frequently a pure pneumococcal or a combined pneumococcal and influenzal infection, is commonly regarded as a fresh superimposed infection by the pneumococcus this is an utterly erroneous view in the great majority of cases."

On the other hand, when there has been a dormant pneumococcal focus in the lung—parenthetically I may remark that needling of the lung has shown me that sometimes the pneumococcus and *B influenzæ* are associated at these foci—

> the factor which above all probably decides the lighting into virulence of the dormant pneumococcus is the incidence of a fresh infection by some other catarrhal micro-organism Chief among these is undoubtedly the *B influenzæ* and it is owing to this fact that an epidemic of influenza is nearly always attended by a greatly raised mortality due to acute pneumonia. At the same time, it must be admitted that a pure invasion of any part of the respiratory tract by the *B influenzæ* is comparatively rare there is nearly always some other associated microbe and this is usually the pneumococcus" (p 107)

The conclusion of the authors, and also of Lieutenant J A. B Hammond, Captain W Rolland, and Lieutenant T H G Shore,[2] that—

> "the primary invasion of the lung tissues is by the *B influenzæ* and that pneumococci present at the same time are at first of low virulence that the earlier symptoms seem to be attributable to a *B influenzæ* toxæmia and that exaltations of the virulence of the pneumococci by symbiotic growth with the *B influenzæ* would appear to follow"—

is therefore a misconception of the process and only a partial statement of the truth especially in view of the experiments I adduced (p 32) to show how potent is the effect of the presence of other bacterial toxins (pneumococcal, staphylococcal, streptococcal) upon the rate of multiplication of the *B influenzæ* At the same time, I am prepared to admit that the *B influenzæ* may be a potent factor in raising the virulence of the pneumococcus

I have been studying closely for nearly 15 years both the clinical aspects and bacteriology of the respiratory tract, and have been much struck by the gradual increase especially during the last four years in the severity of these bronchitic and pneumonic attacks and I can assure the authors that the condition they describe has not been confined to the Aldershot military area nor even to the military as apart from the civilian population I have had large experience of it in private practice and among the New Zealand troops at Codford and Hornchurch So certain was I that a culmination would be reached last winter that I strongly advised the D D M S , N Z E F in England that a special chest hospital should be established and predicted a very high rate of incidence among our troops at Codford which he subsequently informed me had been exceeded The mortality rate at Aldershot was I believe exceeded among the New Zealand troops at Codford The severe epidemics of pneumonia which have ravaged Guatemala city for years (p 104) have I am informed, a mortality rate of 40 per cent It is highly probable that the grouping together of large numbers of men in huts and marquees tends both to raise the rate of incidence and mortality rate, but, as I have stated, the condition freely existed before the war and has been quite common among the civilian population

---

[1] Bacterial Diseases of Respiration and Vaccines in their Treatment 1913 H K Lewis

[2] THE LANCET July 1[illegible]th 1917 (p 44)

Hammond, Rolland and Shore[3] are also in error when they conclude that vaccine treatment is not likely to be of great benefit I have treated many score of cases with vaccines and have found them to be a sheet-anchor, but they should be used as early as possible and before the finer bronchioles are blocked with exudate Antiphlogistine I have found to increase the patient's comfort, especially if combined with the use of medicated steam Mustard plasters, repeated as often as necessary, also help

Three further points I should like to discuss (1) prophylaxis, (2) after treatment, and (3) assessment of the future military value of sufferers from this condition

As regards prophylaxis, this largely hinges upon the prior recognition of cases that have dormant foci in their lungs These foci are nearly always situated in an area limited internally by the nipple line, externally by the anterior axillary line, above by the fifth rib and below by the eighth rib They may usually be heard by means of the stethoscope on very deep respirations being taken, often they can only be elicited post-tussically, occasionally they can only be heard 8 to 16 hours after the administration of a dose of vaccine containing 100 million pneumococci and 200 million *B influenzæ* Prophylaxis in these cases is by means of a suitable vaccine, at weekly intervals beginning in September and January of each year the following doses should be given 100 millions, 250 millions 250 millions, 500 millions, 500 millions pneumococci and twice as many *B influenzæ* In individual cases these dosages may require modification

If prophylactic inoculation be employed it should be confined to those who have been shown to possess the foci I have described, and perhaps extended to those who are especially susceptible to bronchial and pulmonary infections This is rendered necessary by the varied nature of the inoculations which the allied forces already receive The general incidence rate may be much diminished, as I have been convinced by my experiences at Hornchurch, both among those who have infected foci and those who have not, by subjecting the whole camp, officers and men alike, to disinfection of the upper respiratory tract on each of three successive days by means of the chloramine or zinc sulphate atomiser, as at present employed in the case of meningococcus carriers

As regards after treatment, this also is by means of vaccine, and greater attention should be paid to the conditions of life under which these men have to live, in my experience only about 50 per cent ever become quite well again

Finally, as regards the future value of these cases as fighting units for some time every case of respiratory disease in the New Zealand Force passed sooner or later under my care, and in many instances I found myself placed in an awkward position In a certain percentage (about 10 per cent) there was not the least chance of the men ever becoming fit for active service again Do what I would I could not eradicate foci, and the first onset of wet and cold sufficed to stir them up into activity These men were boarded out of the force In a further percentage (30 to 40) the foci appeared to clear up under vaccine and other treatment, but this clearance was I feel sure, more apparent than real Pronounced malaise tachycardia and intermittence of the heart's action, neuritis, myalgia, and gastric disturbances were some of the sequelæ which may persist to a greater or less degree for many months Close observation of these men after graduated exercises is necessary to determine their future value to the Army The remainder made good recoveries but convalescence was nearly always slow, and subsequent training had to be carefully graduated

I am indebted to Lieutenant-Colonel D S Wylie, C M G, officer commanding No 1 New Zealand General Hospital, Brockenhurst, for his kind permission that these notes should receive publication

I am, Sir, yours faithfully,

R W Allen,

Captain N Z M.C No 1 New Zealand General Hospital Brockenhurst Hants

[3] The Lancet July 14th 1917 (p 44)

PEPSIN *VERSUS* NECROSED TISSUE

To the Editor of The Lancet

Sir,—Nothing retards the healing of a wound so much as the presence of necrosed tissue This is removed normally, though with deplorable slowness, by the digestive (tryptic) action of the leucocytes, and I venture to propose a method which would be infinitely quicker than this I do not myself practise surgery, but I see a great many claims for injury under the Workmen's Compensation Act and otherwise, and I have repeatedly noticed how owing to the presence of a deep seated area of necrosed flesh or tendon, the disablement is prolonged and, in some cases, septicæmia results The number of such cases in the present war must be enormous When the area is near the surface the remedy is the knife, but this falls upon the just and the unjust Were it possible to confine the removal to the dead tissues the living remainder might improve the final result Many a deep seated and otherwise harmless bullet too, must be surrounded by dead flesh, which not only prevents the healing of the sinus but imperils the patient's life

Now the phenomenon of peptic ulcer proves that the gastric juice will digest tissue that is dead without involving that through which the blood still circulates, and I propose that the lesson should be applied to contused wounds of a few days' standing if a slough is suspected The best technique can only be evolved from experience, but I feel sure that excellent results will be obtained by the following methods In the case of a sinus leading perhaps to a bullet the wound is first thoroughly well syringed with boiled water, the patient, or his limb, is then placed so that the orifice of the sinus is uppermost and glycerine of pepsin is slowly and interruptedly injected either directly or through an elastic catheter or drainage tube, which is gradually withdrawn while still syringing The orifice is then sealed up with strapping covered with cotton wool, oiled silk, and a lightly applied bandage, and left for four hours, precautions being taken to prevent the temperature from falling At the end of this period digestion will have done its work, though possibly a repetition may be necessary The strapping is therefore removed and the sinus forcibly syringed out with boiled water In the case of superficial sloughs which may or may not enclose islets of still living flesh three or four thicknesses of unmedicated lint well soaked with glycerine of pepsin, or perhaps a mixture of pepsin and water are laid lightly over the part and covered up as before the dressing being renewed every four hours, after pouring water upon the wound from a height

I have never heard of this method of treatment nor do I find any reference to it in books, but, even if it have been already tried, the present war gives opportunities that never existed before, and I plead for a further trial I hope that those who put it to the test will find time to communicate their results to the journals

I am, Sir, yours faithfully,

Ralph W Leftwich M D, C M

The Apple in the Dietary —The Government Order restricting the importation of American and Canadian apples into this country is regrettable since the wholesomeness of the fruit is well recognised A partial fruit diet is consistent with a healthy action all along the line of the alimentary canal and one of the best fruits for the purpose is a sound apple. It is stated that if this order is not withdrawn there will be no apples obtainable as soon as the home supply is exhausted, which is about the end of November, and many people who enjoy eating an apple and find it a healthy auxiliary to their dietary will probably have to forgo these advantages While the apple possesses a limited nutritive value of direct importance, the peculiar dispensation of its acids salts, pectins, sugars, and tissue renders it a very wholesome adjunct to diet and one which undoubtedly contributes to healthy metabolism

The War

THE CASUALTY LIST

THE following names of medical officers appear among the casualties announced since our last issue —

Died of Wounds

Capt W J Evans, R A M C attached Gloucester Regiment received his medical education at University College Hospital, qualified in 1916, and joined up forthwith

Wounded

Capt A Morris, R A M C attached Royal Warwick Regt
Capt B N Murphy, M C, R A M C, attached Coldstream Guards
Capt A Willatt, R A M C attd Northumberland Fusiliers
Capt D E Scott, R A.M C attd Dublin Light Infantry
Capt C H L Rixon R A M C, attd Sherwood Foresters
Major J H Dixon, R A M C
Capt A. Gaston R A.M C, attd South Staffordshire Regt
Capt F F Dunham, Canadian A M C

CASUALTIES AMONG THE SONS OF MEDICAL MEN

The following additional casualties among the sons of medical men are reported —

Lieut A F V Stephenson, Gordon Highlanders died of wounds, younger surviving son of Dr. W Stephenson, Emeritus Professor of Midwifery, University of Aberdeen
Lieut M W von Winckler, Middlesex Regiment killed in action only son of Dr W J von Winckler, of Georgetown, British Guiana
Capt O Thomas, Welsh Horse Yeomanry, died of cardiac failure, second son of the late Dr J L Thomas, of Southampton
Lieut Col A G Johnson Royal Artillery killed in action eldest son of the late Dr J Johnson, of Tunbridge Wells
Lieut C S Workman, M C, Cameronians and Royal Flying Corps died of wounds, younger son of Dr C Workman, of Glasgow
Major R D Harrisson D S O Royal Field Artillery, killed in action only child of Col D Harrisson, A M S, of Liverpool

MENTIONED IN DESPATCHES

The names of the following medical officers are mentioned in the despatches detailed —

From Vice Admiral Sir R E Wemyss K C B, C M G, M V O dealing with the operations of H M gunboats in Mesopotamia from December, 1916 to March, 1917—

Surg J C Kelly R N, H M S *Tarantula*
Attended to wounded whilst fire was at its hottest in an exposed position.

Surg James P Shorten, R N, H M S *Mantis*
Continued to dress and attend to the wounded in the open while under very heavy fire

Surg Frederick G E Hill, R N, H M S *Moth*
Finding a man wounded on the battery deck he gallantly under heavy fire carried him into the sick bay to dress his wounds Whilst doing this the man received another wound through his throat and Surgeon Hill himself received a nasty wound in his forearm Nevertheless although in considerable pain and until his arm became too stiff to use it he proceeded to dress and attend to all the wounded on board

Temp Surg Robert G Elwell R N H M S *Gadfly*
Rendered valuable service under fire on many occasions

Staff Surgs Thomas W Jeffery, R N (H M.S *Proserpine*) and George W Vickery, R N (H M S *Dalhousie*)
Recommended for good services at the base which contributed largely to the successful operations

From Lieutenant General A R Hoskins C M G, D S O Commander in Chief East African Force dated March 14th—

Lieut Col R L Girwood S.A Medical Corps, Major E T Harris I M S Temp Lieut Col A D Milne, East African Medical Service, Lieut Col H W Vaughan Williams S A Medical Corps

From the Governor of Nyasaland (Sir G Smith) and Brigadier General Northey C B dated March 10th dealing with the operations of the Nyasaland Rhodesia Force—

Temp Lieut Col H H V Hearsey P M O Nyasaland Government Director of Military Medical Services Major D M MacGregor S A Medical Corps Temp Major H S Stannus Capt (temp Major) W I L A Holcroft S A Medical Corps, Surg Capt R S White Northern Rhodesia Medical Service Surg Capt R R Murray Northern Rhodesia Medical Service Surg Capt A F Wallace Northern Rhodesia Medical Service Surg Cap R Burr, Nyasaland Field Force Surg Capt J W Bouwer, S A Medical Corps, Surg Capt W J Sheehan, Northern Rhodesia Medical Service Surg Capt E Storrs Northern Rhodesia Medical Service Capt M G Sanderson, Nyasaland Field Force Capt R L Lloyd, M C, S A Medical Corps, Capt A P M Anderson S A Medical Corps, Capt A. W Forrester Rhodesia Medical Service, Temp Lieut P A Lister Smith, Nyasaland Field Force

THE HONOURS LIST

The following awards to medical officers are announced —

Distinguished Service Order

Surg Frederick G E Hill R N

Distinguished Service Cross

Surg James C Kelly, R N
Surg James P Shorten R N
Surg Robert G Elwell, R N

FOREIGN DECORATIONS

THE SUBSTITUTION OF AMERICAN DOCTORS FOR CIVIL MEDICAL PRACTITIONERS IN MILITARY HOSPITALS

At the meeting of the Central Medical War Committee on Wednesday last this important subject was considered in connexion with a memorandum submitted by the chairman of the Committee The situation having been thus explained to the Committee and debated by them, it was decided that a representation should be made to the Director General of the Army Medical Service asking that the Committee should be consulted on all matters affecting civilian medical men The statement in the lay press that the process of substitution as far as it has gone was in accordance with the expressed wishes or views of the Central Medical War Committee was entirely erroneous

SWEATERS

We have received the following letter from Mr John Penoyre and feel sure that our readers will bring its contents before their patients and friends at all opportunities —

Are your good readers going to prove good friends to "Sweaters" again for this the fourth winter of the war? We have made a good start with 10 999 comforts sent me as the result of a summer knitting appeal The sweaters and other things have outgrown this garret so will your readers kindly address the sacks and parcels to me care of Sir Edward Ward D G V O 45, Horseferry road, S W 1 They will have heard all about Sir Edward's Central Pool of Comforts with its bases on every front, from which officers can draw direct for exactly what their men need Waste and delay are thus avoided but it is a point of honour for us all to keep these base depots well supplied throughout the winter I know all about the wool difficulty but we can but do our best and be of good cheer bearing in mind that this may be the last winter of the war

I have here at 8 King's Bench Walk, Temple, E C 4, plenty of easily knitted printed patterns of all comforts for any ladies who like to write for them They are, of course, free but it is considerate to enclose stamps to cover postage

THE RED CROSS EMBLEM —In order to prevent the improper use of the Red Cross emblem on privately-owned motor cars and other vehicles, a notice has been issued by the Secretary of the War Office stating that owners of all vehicles who desire to obtain permission to display the emblem must make application through the headquarters of the command by which their cars are employed The application will be forwarded to the War Office and the necessary permit issued if the car in question fulfils the following conditions (1) That it is used solely for the conveyance of sick and wounded soldiers, and (2) that it has been placed at the disposal of the military authorities for this purpose rate, but, as I have stated, the condition freely existed before the war and has been quite common among the civilian population

Hammond, Rolland and Shore[3] are also in error when they conclude that vaccine treatment is not likely to be of great benefit I have treated many score of cases with vaccines and have found them to be a sheet-anchor, but they should be used as early as possible and before the finer bronchioles are blocked with exudate Antiphlogistine I have found to increase the patient's comfort, especially if combined with the use of medicated steam Mustard plasters, repeated as often as necessary, also help

Three further points I should like to discuss (1) prophylaxis, (2) after treatment, and (3) assessment of the future military value of sufferers from this condition

As regards prophylaxis, this largely hinges upon the prior recognition of cases that have dormant foci in their lungs These foci are nearly always situated in an area limited internally by the nipple line, externally by the anterior axillary line, above by the fifth rib, and below by the eighth rib They may usually be heard by means of the stethoscope on very deep respirations being taken, often they can only be elicited post-tussically, occasionally they can only be heard 8 to 16 hours after the administration of a dose of vaccine containing 100 million pneumococci and 200 million *B influenzæ* Prophylaxis in these cases is by means of a suitable vaccine, at weekly intervals beginning in September and January of each year the following doses should be given 100 millions, 250 millions, 250 millions, 500 millions, 500 millions pneumococci and twice as many *B influenzæ* In individual cases these dosages may require modification

If prophylactic inoculation be employed it should be confined to those who have been shown to possess the foci I have described, and perhaps extended to those who are especially susceptible to bronchial and pulmonary infections This is rendered necessary by the varied nature of the inoculations which the allied forces already receive The general incidence rate may be much diminished, as I have been convinced by my experiences at Hornchurch, both among those who have infected foci and those who have not, by subjecting the whole camp, officers and men alike, to disinfection of the upper respiratory tract on each of three successive days by means of the chloramine or zinc sulphate atomiser, as at present employed in the case of meningococcus carriers

As regards after treatment, this also is by means of vaccine, and greater attention should be paid to the conditions of life under which these men have to live, in my experience only about 50 per cent ever become quite well again

Finally, as regards the future value of these cases as fighting units for some time every case of respiratory disease in the New Zealand Force passed sooner or later under my care, and in many instances I found myself placed in an awkward position In a certain percentage (about 10 per cent) there was not the least chance of the men ever becoming fit for active service again Do what I would I could not eradicate foci, and the first onset of wet and cold sufficed to stir them up into activity These men were boarded out of the force In a further percentage (30 to 40) the foci appeared to clear up under vaccine and other treatment, but this clearance was I feel sure, more apparent than real Pronounced malaise tachycardia and intermittence of the heart s action, neuritis, myalgia, and gastric disturbances were some of the sequelæ which may persist to a greater or less degree for many months Close observation of these men after graduated exercises is necessary to determine their future value to the Army The remainder made good recoveries but convalescence was nearly always slow, and subsequent training had to be carefully graduated

THE following names of medical officers appear among the casualties announced since our last issue —

Died of Wounds

Capt W J Evans, R A M C attached Gloucester Regiment received his medical education at University College Hospital, qualified in 1916, and joined up forthwith

Wounded

Capt A Morris R A.M C attached Royal Warwick Regt
Capt B N Murphy, M C, R A M C, attached Coldstream Guards
Capt A Willett R.A M C attd Northumberland Fusiliers
Capt D E Scott, R.A.M C attd Dublin Light Infantry
Capt C H L Rixon R.A M C, attd Sherwood Foresters
Major J H Dixon, R A M.C
Capt A Gaston R A.M C attd South Staffordshire Regt
Capt F F Dunham, Canadian A.M C

CASUALTIES AMONG THE SONS OF MEDICAL MEN

The following additional casualties among the sons of medical men are reported —

Lieut A F V Stephenson Gordon Highlanders died of wounds, younger surviving son of Dr. W Stephenson, Emeritus Professor of Midwifery University of Aberdeen

Lieut M W von Winckler Middlesex Regiment, killed in action only son of Dr W J von Winckler, of Georgetown British Guiana

Capt O Thomas, Welsh Horse Yeomanry died of cardiac failure, second son of the late Dr J L Thomas, of Southampton

Lieut Col A G Johnson Royal Artillery killed in action eldest son of the late Dr J Johnson, of Tunbridge Wells

Lieut. C S Workman, M C, Cameronians and Royal Flying Corps died of wounds, younger son of Dr C Workman, of Glasgow

Major R D Harrisson D S O Royal Field Artillery killed in action only child of Col D Harrisson A.M S of Liverpool

MENTIONED IN DESPATCHES

The names of the following medical officers are mentioned in the despatches detailed —

From Vice Admiral Sir R E Wemyss K.C B, C M G, M V O, dealing with the operations of H.M gunboats in Mesopotamia from December 1916 to March, 1917—

Surg J C Kelly R N H M S *Tarantula*
Attended to wounded whilst fire was at its hottest in an exposed position.

Surg James P Shorten, R N H M S *Mantis*
Continued to dress and attend to the wounded in the open while under very heavy fire

Surg Frederick G E Hill, R N H.M S *Moth*
Finding a man wounded on the battery deck, he gallantly under heavy fire carried him into the sick bay to dress his wounds Whilst doing this the man received another wound through his throat and Surgeon Hill himself received a nasty wound in his forearm Nevertheless although in considerable pain and until his arm became too stiff to use it he proceeded to dress and attend to all the wounded on board

Temp Surg Robert G Elwell R N H M S *Gadfly*
Rendered valuable service under fire on many occasions

Staff Surgs Thomas W Jeffery, R N (H M S *Proserpine*), and George W Vickery R N (H M S *Dalhousie*)
Recommended for good services at the base which contributed largely to the successful operations

From Lieutenant General A R Hoskins C M G D S O Commander in Chief East African Force dated March 14th—

Lieut Col R L Girwood S.A Medical Corps Major E T Harris I M S Temp Lieut Col A. D Milne, East African Medical Service Lieut Col H W Vaughan Williams S A Medical Corps

From the Governor of Nyasaland (Sir G Smith) and Brigadier General Northey C.B dated March 10th dealing with the operations of the Nyasaland Rhodesia Force—

Temp Lieut Col H H V Hearsey P M O Nyasaland Government Director of Military Medical Services Major D M MacGregor S A Medical Corps Temp Major H S Stannus Capt (temp Major) W F L A Holcroft S A Medical Corps Surg Capt R S White Northern Rhodesia Medical Service Surg Capt R R Murray Northern Rhodesia Medical Service Surg Capt A F Wallace Northern Rhodesia Medical Service Surg Capt R Burr Nyasaland Field Force Surg Capt J W Louwer S.A Medical Corps, Surg Capt W J Sheehan, Northern Rhodesia Medical Service Surg Capt E Storrs Northern Rhodesia Medical Service Capt M G Sanderson, Nyasaland Field Force Capt R L Lloyd M.C, S A. Medical Corps, Capt A. P M Anderson S.A Medical Corps, Capt A. W Forrester Rhodesia Medical Service, Temp Lieut P A. Lister Smith, Nyasaland Field Force

THE HONOURS LIST

The following awards to medical officers are announced —

THE SUBSTITUTION OF AMERICAN DOCTORS FOR CIVIL MEDICAL PRACTITIONERS IN MILITARY HOSPITALS

At the meeting of the Central Medical War Committee on Wednesday last this important subject was considered in connexion with a memorandum submitted by the chairman of the Committee The situation having been thus explained to the Committee and debated by them it was decided that a representation should be made to the Director General of the Army Medical Service asking that the Committee should be consulted on all matters affecting civilian medical men. The statement in the lay press that the process of substitution as far as it has gone was in accordance with the expressed wishes or views of the Central Medical War Committee was entirely erroneous

SWEATERS

We have received the following letter from Mr John Penoyre, and feel sure that our readers will bring its contents before their patients and friends at all opportunities —

Are your good readers going to prove good friends to "Sweaters" again for this the fourth winter of the war? We have made a good start with 10,999 comforts sent me as the result of a summer knitting appeal The sweaters and other things have outgrown this garret, so will your readers kindly address the sacks and parcels to me care of Sir Edward Ward D G V O, 45, Horseferry road S W 1 They will have heard all about Sir Edward's Central Pool of Comforts with its bases on every front from which officers can draw direct for exactly what their men need Waste and delay are thus avoided but it is a point of honour for us all to keep these base depots well supplied throughout the winter I know all about the wool difficulty but we can but do our best and be of good cheer bearing in mind that this may be the last winter of the war

I have here at 8 King's Bench Walk Temple E C 4, plenty of easily knitted printed patterns of all comforts for any ladies who like to write for them They are of course, free but it is considerate to enclose stamps to cover postage

THE RED CROSS EMBLEM —In order to prevent the improper use of the Red Cross emblem on privately owned motor cars and other vehicles a notice has been issued by the Secretary of the War Office stating that owners of all vehicles who desire to obtain permission to display the emblem must make application through the headquarters of the command by which their cars are employed The application will be forwarded to the War Office and the necessary permit issued if the car in question fulfils the following conditions (1) That it is used solely for the conveyance of sick and wounded soldiers, and (2) that it has been placed at the disposal of the military authorities for this purpose

URBAN VITAL STATISTICS

(Week ended Sept 22nd, 1917)

English and Welsh Towns —In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 17 000 000 persons the annual rate of mortality was 11·1, against 11·1 and 10·6 per 1000 in the two preceding weeks In London, with a population exceeding 4,000 000 persons the death rate was also 11·1 per 1000 while among the remaining towns it ranged from 2·1 in Swindon, 3·1 in Reading and 4·0 in Cambridge to 17·9 in Wimbledon, 21·6 in Gateshead and 21·8 in Stockton-on Tees The principal epidemic diseases caused 470 deaths which corresponded to an annual rate of 1·4 per 1000 and included 344 from infantile diarrhœa, 39 from diphtheria 38 from whooping-cough 35 from measles, and 7 each from enteric fever and scarlet fever The deaths from diarrhœa, which had been 312, 320 and 262 in the three preceding weeks rose to 344 and included 90 in London 27 in Liverpool, 17 in Sheffield, 16 in Manchester and 12 each in Hull and Newcastle-on Tyne The 732 cases of scarlet fever and 1082 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were respectively 49 and 45 above the numbers remaining at the end of the previous week. Of the deaths in the 96 towns 107 resulted from violence The causes of 25 deaths were uncertified, of which 3 were registered in Liverpool and 3 in Bootle.

Scotch Towns —In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2 500 000 persons the annual rate of mortality was equal to 11·6 against 12·6 and 10·8 per 1000 in the two preceding weeks The 257 deaths in Glasgow corresponded to a rate of 12·0 per 1000 and included 24 from infantile diarrhœa 6 from whooping cough 3 from diphtheria and 1 each from measles and scarlet fever The 64 deaths in Edinburgh were equal to an annual rate of 10·1 per 1000 and included 2 each from whooping-cough and infantile diarrhœa, and 1 from diphtheria.

Irish Towns —The 127 deaths in Dublin corresponded to a rate of 16·6, or 1·6 per 1000 above that recorded in the previous week and included 9 from infantile diarrhœa, 2 from whooping-cough and 1 each from measles and diphtheria The 109 deaths in Belfast were equal to an annual rate of 14·5 per 1000 and included 7 from infantile diarrhœa, 2 from whooping cough, and 1 from enteric fever

VITAL STATISTICS OF LONDON DURING AUGUST 1917

In the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the ten diseases specified in the table was equal to an annual rate of 3·1 per 1000 of the population estimated at 4 237,387 persons in the three preceding months the rates were 3·5 3·4 and 3·5 per 1000 respectively The lowest rates were recorded last month in Paddington Kensington, Fulham, St Marylebone, Holborn and Battersea and the highest rates in Finsbury Shoreditch, Bethnal Green Stepney Southwark Bermondsey and Greenwich The prevalence of scarlet fever was less than in any of the preceding months of this year this disease was proportionally most prevalent last month in Shoreditch Bethnal Green Stepney Bermondsey, Wandsworth, and Lewisham The Metropolitan Asylums Hospitals contained 616 scarlet fever patients at the end of last month against 613 595 and 644 at the end of the three preceding months the weekly admissions averaged 83 against 92, 83 and 101 in the three preceding months Diphtheria was considerably less prevalent than in any other recent month the greatest proportional prevalence of this disease last month was recorded in the City of London Finsbury Shoreditch Bethnal Green Stepney Southwark, Bermondsey, and Greenwich There were 1003 diphtheria patients under treatment in the Metropolitan Asylums Hospitals at the end of last month against 1048 1042, and 1070 at the end of the three preceding months the weekly admissions averaged 122, against 129 138 and 142 in the three preceding months The prevalence of enteric fever was below that recorded in either of the two preceding months this disease was proportionally most prevalent last month in Hammersmith Chelsea Stepney and Deptford The Metropolitan Asylums Hospitals contained 45 enteric patients at the end of last month against 31 and 41 at the end of the two preceding months; the weekly admissions during the month averaged 6 against 6 and 7 in the two preceding months Erysipelas was proportionally most prevalent in St Pancras Hackney Stoke Newington Shoreditch and Southwark The 19 cases of puerperal fever notified during the month included 3 each in Stepney and Wandsworth, and 2 each in Islington and Lewisham Of the 10 cases of cerebro-spinal meningitis 2 belonged to Battersea while the 4 cases of poliomyelitis belonged respectively to Fulham Chelsea, Poplar, and Battersea

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the five weeks ending Sept 1st the deaths of 4261 London residents were registered, equal to an annual rate of 10·5 per 1000 of the population in the three preceding months the rates were 13·9 12·0 and 10·9 per 1000 respectively The death rates last month ranged from 4·7 in the City of London 7·8 in Woolwich, 8·1 in Wandsworth, 8·3 in Hampstead 8·5 in Hackney and 8·7 in Lewisham to 12·1 in Southwark 12·3 in Stepney 12·5 in Finsbury 13·1 in Chelsea, 14·2 in Shoreditch, and 15·1 in Bermondsey The 4261 deaths from all causes included 476 which were referred to the principal infectious diseases of these 59 resulted from measles, 8 from scarlet fever, 35 from diphtheria, 37 from whooping-cough, 15 from enteric fever, and 322 from diarrhœa and enteritis among children under 2 years of age. No death from any of these diseases was recorded in the City of London among the metropolitan boroughs they caused the lowest death rates in Chelsea, the City of Westminster St Marylebone Hampstead Holborn and Lewisham and the highest death rates in Shoreditch, Stepney, Poplar Bermondsey and Greenwich The 59 deaths from measles were 45 below the corrected average number in the corresponding period of the five preceding years this disease was proportionally most fatal last month in Kensington Hammersmith Islington Shoreditch Stepney and Poplar The 8 fatal cases of scarlet fever showed a decline of 11 from the corrected average number and included 2 in Southwark and 1 each in Paddington, St Pancras Hackney Lambeth Wandsworth, and Camberwell The 35 deaths from diphtheria were 2 fewer than the average the greatest proportional mortality from this disease occurred in the City of Westminster,

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING AUGUST 1917

LEWER —On Sept 18th, at his residence Wickham Burley in Wharfedale Yorkshire Edward Stewart Lewer, M D aged 51

N.B —A fee of 5s is charged for the insertion of Notices of Births Marriages and Deaths

Notes, Short Comments, and Answers to Correspondents.

BACTEROL

THIS is a disinfectant containing among other things formalin and essential oils compounded at a high temperature It is prepared in four forms (*a*) Medical type for medical use treatment of wounds &c , (*b*) general type for general use, (*c*) *vaporising fluid for disinfection* with the vapour, and (*d*) aeriform type for inhalation

Bacterol Sterilising Cabinet —This is a light wooden box or chamber made in various sizes Bacterol vaporising fluid is vaporised and the vapour is passed into the cabinet in which the articles to be disinfected have been placed The bacterol is vaporised by a special apparatus consisting of copper coil heated with a blow lamp The temperature in the cabinet does not rise above 100°F The vapour is fatal to bacteria, including anthrax spores, and is a powerful insecticide, killing lice, clothes moth, wood worm &c The cabinet is used by brush manufacturers for sterilising hair for brushes since the occurrence of anthrax caused by shaving brushes, and is employed by the Y M C A for killing lice and other vermin in bedding and clothing The vapour has no deleterious action upon clothing bedding, coloured fabrics, furs leather &c

Isle of Wight Disease of Bees —Many experienced bee keepers assert that bacterol is a cure for this disease Sugar syrup is medicated with bacterol and given to the bees The hives are sprayed with a *1 in 80* solution of bacterol For the winter feeding of bees with sugar syrup the Government has set aside 20 tons of sugar This has been allotted to Messrs Pascall to deal with The Board of Agriculture has stipulated that this sugar shall be converted into "candy and be medicated with bacterol and coloured with a pink dye so as to render it unfit for human consumption It is placed on the market under the name of "*Pink Bacterol Bee Food*

Medical Uses —For all surgical purposes—for lotions gargles, sprays, &c Bacterol appears to be particularly valuable in the local treatment of venereal and other sores and ulcers The aeriform type is valuable for cutting short catarrhal affections of the respiratory tract Bacterol is practically non toxic It is prepared by Messrs Menley and James, Limited, Menley House, Farringdon road, London, E C

AILMENTS OF MINOR POETS

HINTS FOR MEDICAL PRACTITIONERS

To the Editor of THE LANCET

SIR,—Reference was *recently* made in THE LANCET to the increased activity of our minor poets Scarcely a day passes but some new volume of verse makes its appearance And the average excellence of these little books is commendably *high For the modern singer* is, as a rule, well aware of the wisdom of the adage which proclaims brevity to be the soul of wit He seldom seeks to inflict on us an epic in 12 books or a didactic poem with notes and an appendix. Indeed the *fair white margins* whereon his lyrics shyly hide themselves are sometimes so expansive that we have to hunt around to find his sonnet with almost as much persistence as an air pilot tracking down a submarine *And for* this we thank him For very *few poets*—even of the major variety—are gifted with sufficient emotional opulence to ensure us quantity as well as quality But there are still occasions when the minor poet, in the exuberance of youth (*and sometimes, alas, in the* exuberance of age!) not merely 'devotes himself but "abandons himself to poetry Abandonment is bad In his abandoned state he is in danger not only of losing sight of the paper shortage but also of *falling a victim to many* regrettable ailments To assist the medical practitioner in affording relief to such cases the following brief hints will, it is hoped, prove *of service*

1 *Heart fractures* —The sufferer from this complaint will probably describe his condition in lines conveying in appropriate terms the following information :—

> I feel that my heart is breaking
> Though I try *for your sake to smile*

When called in to a case like this don t waste time in argument. Clap a stethoscope on the *patient s* chest and listen If the heart 's breaking there is considerable danger—and not only *to the patient.* The hearts of minor poets *not only break " they sometimes* burst " Stand clear and take cover if possible Charge double fees to cover *the* additional risk

2. *Inability to die.*—Some poets are fond of declaiming I could not die in Springtime " or *I could not* die in Summer " or How could I pass on such a night as this?" rhyming this" (in the next line but one) with kiss " Cases of this kind *should* be confronted with

instant proof Lose no time in prescribing a stiff dose of prussic acid. If the sufferer really finds it impossible to die he will not refuse to take the stuff And should the action of the potion prove he was misinformed there will be one minor poet the less. For this you will earn the lyrical gratitude of the other minor poets.

3. *Prolonging the season* — "With You tis always Summer dearest Friend" this kind of statement is constantly being made by minor poets They labour under a delusion. Not even the Summer Time Act has been able to prolong summer To cure this strange obsession choose the bleakest day of January, take the patient—clad in summer attire—to the house of the "dearest Friend" and persuade him (or her) to sit in the garden for a couple of hours As soon as the teeth begin to chatter ask whether it is winter or summer You will certainly receive an accurate though probably unrhymed answer

4 *Seeing angels* — "Thou art an Angel, O my Love" Such a statement is indicative of mental trouble Nearly all minor poets mistake their loves some time or other for angels. There is only one way to cure them of this sad mistake Insist upon the patient marrying the object of his (or her) affections immediately By this treatment the angelic obsession will gradually become dislodged.

5. *Scalds from kisses* —When a minor poet ejaculates "I feel thy burning kiss upon my cheek" you will know that he is in considerable danger Lose no time in applying to his cheek butter margarine, train-oil or any old lubricant you can lay hands on If after this he still insists that the kiss burnt him you had better commit him to the county asylum

6. *Ocular stabbings* —Minor poets are frequently the victims of outrages of this kind. How often do they cry "Your glance has stabbed me to the core" or words to that effect? If on being called in, you find that the "core" has really been punctured, get a cycle repair outfit and proceed as you would with a burst tyre To locate puncture hold the patient under water and watch for bubbles

7 *Retention of tears* —Minor poets are not infrequently attacked by a curious affection of the tear glands which they express in some such words as the following —

"How can I weep when earth and sea and sky
Are one vast Ecstasy"

Talk to the sufferer kindly Point out to him that a spell of bad weather is certain to set in before long and that these "vast ecstasies" seldom survive the summer You can also assure him that many people who shed tears at extremely rare intervals have nevertheless lived to a ripe—and even a rotten—old age and died of another complaint in the end. In acute cases insist on the use of onions

8. *Exchange of diaphragms* —Was it not Sir Philip Sidney who sang "My true love hath my heart and I have his"? Minor poets have frequently said the same thing since—only not so well. If called in to attend a case of this nature you will have *to* proceed cautiously It is the most difficult thing in the world to determine whether a patient is in possession of his own heart or somebody else's they are all so alike. And nobody is anxious to give up his heart Your best plan will be to insist on a thorough examination with X rays and try to determine whether the respective hearts fit. In cases where the patient has a fit there will be no more to be done

I am Sir, yours faithfully and apologetically,

Sept. 19th 1917 R B I

HOSPITAL WORK IN FIJI.

ACCORDING to the Fiji Blue-book for 1916 the population increased during the year by 24 024, and now totals 163 565 The Colonial Hospital the principal medical institution in the colony, is under the supervision of the chief medical officer with a resident medical officer in charge who is assisted by a junior medical officer The nursing staff consists of a matron, a senior and a junior staff nurse, a graduate nurse and six probationers The number of patients treated in 1916 was 1778, of whom 185 were Europeans There is at Levuka a branch hospital under the charge of the district medical officer assisted by a European and a native nurse, admissions during 1916 were 483 There are 11 provincial hospitals for the treatment of native Fijians these are supervised by Government medical officers and the admissions totalled 5271 There is a lunatic asylum at Suva for the reception of both sexes of all nationalities, with separate accommodation for Europeans During 1916 there were 39 admissions and 19 discharges and there were 56 patients at the close of the year On Dec 31st, 1916, there were 257 patients in the leper asylum on the island of Makogai which is under the charge of a medical superintendent who is assisted by a European medical officer and five European and three Fijian nursing sisters

WANTED TRAINING ON A DAIRY FARM

To the Editor of THE LANCET

SIR —Can any of your readers put me in touch with a farmer of good social position in a southern county who would entertain the idea of taking into his household a young lady who desires to learn dairy farming?

I am Sir yours faithfully

LEONARD MOLLOY

3 Bligh on parade Blackpool Sept 19th 1917

Idue —We will attempt to deal with a very disputed subject in an early issue

Tenax —We are obliged to our correspondent for a useful letter but he has omitted to entrust us with his name and address.

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession may be sent direct to this office

Lectures, original articles and reports should be written on one side of the paper only *and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification*

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot undertake to return MSS not used

Offices 423, STRAND, LONDON, W C 2.

MANAGER'S NOTICES

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423 Strand, London, W C 2, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c, should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

THE COLONIAL AND FOREIGN EDITION is published in time to catch the weekly Friday mails to all parts of the world

A Report
ON
THE PATHOLOGY DIAGNOSIS AND TREATMENT OF ABSOLUTE HYSTERICAL DEAFNESS IN SOLDIERS

BY A F HURST, M D OXON, F R C P LOND,
PHYSICIAN AND NEUROLOGIST TO GUY'S HOSPITAL, AND NEUROLOGIST TO R.V H NETLEY TEMPORARY MAJOR, R.A.M C

AND

E A. PETERS, M D CAMB, F R C S ENG,
SURGEON ROYAL EAR HOSPITAL, AND AURAL SURGEON TO R.V.H NETLEY TEMPORARY CAPTAIN R.A.M.C.

TWO CASES OF HYSTERICAL DEAFNESS CURED BY "OPERATION"

THE following case of hysterical deafness following shell shock was cured by operation"

Lance Corporal M 26 years old, was blown up by a shell on August 29th, 1916 He became completely blind, deaf, and dumb, although he did not lose consciousness His sight returned the following day On reaching England he was able to read and write, and he talked in his sleep In spite of treatment with encouragement, electricity, and etherisation, no further improvement occurred until one night in November, when he woke up and asked the sister for a drink. After this he was able to talk normally, but the deafness remained

The patient was transferred to the Neurological Section at Netley on March 21st 1917 seven months after the onset of deafness He was found to be completely deaf both to air and bone conduction, though he could feel the vibration of a tuning fork on his mastoid A loud noise just behind his head caused a slight tremor of his hands, blinking and dilatation of the pupils although he heard nothing a slighter reaction was produced on the second and third occasion when the noise was repeated, after this it disappeared completely and did not return again

The functional activity of the vestibular nerve and semicircular canals was then tested the normal nystagmus and giddiness demonstrated that this system was unaffected As our experience shows that organic disease or injury of sufficient intensity to produce severe cochlear deafness is invariably accompanied by loss of vestibular activity, we were assured that the internal ear was free from organic changes This was rendered still more probable by the fact that immediately after the explosion the deafness was associated with mutism, which is always hysterical when it develops after shell shock. The patient was hypnotised by being made to stare at a lens for 15 seconds but the deafness persisted he could not be made to respond to any suggestion as he was unable to hear and a very loud noise produced no auditory motor reflex the pupils as well as the eyelids remaining fixed

The deafness also persisted during natural sleep, as it was found impossible to wake the patient by shouting "fire" and by banging a poker against a coal scuttle within a few inches of his head and no reflex contraction of his eyelids was observed In the morning he had no recollection that anything unusual had occurred during the night Suggestion with the aid of electricity in which he had great belief and attempts to re educate the sense of hearing with various noises completely *failed*

On April 16th he was told that if in spite of the treatment he had had before and since admission his hearing had not returned by the 20th we should have to do a small operation on his ear which would be certain to cure him As his hearing had not improved on the 20th he readily consented to the operation Two small superficial incisions were made behind his ear under light etherisation and a suture was inserted A loud noise was made during the operation, he heard it and jumped off the table In the course of the next few minutes normal hearing returned in both ears to his intense delight as he had recently become extremely depressed at the absence of any sign of improvement after seven and a half months His hearing was accurately tested the next day and it was found that it was perfectly normal both to air and bone conduction and the auditory motor reflexes had returned He was discharged to duty three weeks later feeling perfectly fit He visited the hospital on June 29th a few days before he left for France His hearing was normal and he was well in every way

Another case of hysterical deafness following gun deafness was also cured by "operation"

Gunner F, aged 18, says he has been slightly deaf all his life He became gradually deafer after gun practice whilst training in England until he could not hear at all, although he had never suffered from any definite concussion and had not served abroad He was totally deaf to air and bone conduction, and it was impossible to wake him by the loudest noises when he was asleep The deafness also persisted during deep hypnosis so that he could not be made to respond to suggestion The normal nystagmus and giddiness followed rotation, and he had a brisk auditory motor reflex both when awake and during sleep, but it was clear that this was not associated with hearing

Ordinary persuasion, suggestion, and hypnotism having failed to produce any improvement after five months, he was advised to undergo an operation, which he was told would certainly cure him He was given a little ether, and an incision was made behind his right ear, a plate of iron being continuously hammered at the same time He jumped from the table in a half-drunken condition, hearing quite well, and said he must have had a dream, as he thought he had been deaf The next day he said that he could hear better than he had ever done before He was discharged to duty 10 days later Two months later a report was received that his hearing remained good, he was doing his work well, and had applied for a commission

Examination of his ears a week after the operation showed that he could only hear a 30-inch watch at 20 inches, the upper and lower limits of hearing were normal Both drums were indrawn and showed evidence of chronic catarrh which was doubtless the cause of his long standing deafness He was thus predisposed by chronic ear disease to gun-deafness and the temporary deafness produced during gun practice was perpetuated and exaggerated by auto-suggestion The true gun-deafness had disappeared spontaneously, so that when the total deafness resulting from suggestion was cured by suggestion in the form of an operation, his hearing returned to its original state

ETIOLOGY

The momentary deafness which is the natural result of the terrific noise caused by the explosion of a big shell in the immediate neighbourhood may make such an impression on the mind of a soldier that on coming to himself whether he has actually lost consciousness or not his first thought is for his hearing especially if it was already impaired by preceding disease, and he may be so convinced that he is permanently deafened that he becomes actually deaf as a result of auto-suggestion

The temporary deafness which occurs in gunners from the effect of the constant repetition of very loud noises may in the same way become perpetuated and exaggerated by auto-suggestion

Lastly organic deafness especially if the onset is acute, as in that due to involvement of the auditory nerve trunk in cerebro spinal fever, may remain complete after the disappearance of the active inflammation has been followed by restoration of some of the nerve fibres, so that a certain amount of hearing should have returned This, again is due to auto-suggestion, the final deafness being organic with a superadded hysterical element which is capable of removal like all hysterical symptoms by suggestion

DIAGNOSIS

We have found it necessary to discard almost all the criteria formerly used in the diagnosis of organic deafness from deafness due to hysteria or malingering

1 *History* —Severe deafness following the explosion of a powerful shell is generally hysterical though a lesser degree of organic deafness of a more or less permanent nature may be produced at the same time owing to rupture of the drum or hæmorrhage into the tympanum which are often followed by infection of the middle ear or to interference with the cochlear and vestibular systems probably due to infiltration œdema or hæmorrhage into the labyrinth It is doubtful whether absolute organic deafness ever results from hæmorrhage into the internal ear following shell shock as no anatomical evidence of such an occurrence has yet been forthcoming Deafness following an acute illness especially cerebro-spinal fever is at any rate always organic, but the deafness is in our experience frequently increased as a result of auto suggestion no functional improvement occurring when the anatomical condition improves

2 *Bone and air conduction* —We have employed the following quantitative tests

(*a*) Watch test for air conduction The distance a watch is heard (x) is expressed as a fraction of the distance at which it is heard by the normal ear (y) $\frac{x}{y}$

(*b*) Modified Schwabach test for bone conduction The base of a vibrating C tuning fork is held to the base of the mastoid whilst the other hand curtains the meatus The patient holds up his finger when the sound is no longer heard, the observer then transfers the tuning fork to his own normal mastoid and notes the number of additional seconds during which he hears the fork

These tests and comparison between bone and air conduction as in Rinne's test, are, however, only of value in the slighter cases, as in many instances deafness is absolute and no hearing is possible whether the sound is conducted by bone or through the air The vibration of a tuning fork held on the mastoid process is often felt and the aerial vibration caused by very loud noises is often appreciated, even when no sound is heard,

3 *Auditory motor or jump reflex* —A sudden noise normally causes an individual to jump and often to blink and the pupils dilate, the "jump," at any rate, is a protective reflex and represents the preparation for flight or fight An officer whose left motor cortex had been almost completely destroyed went to *The Man who Stayed at Home* about four months after he was wounded His right arm jumped violently when the gun shot rang out on the stage, although no trace of voluntary movement returned until three months later The efferent part of the reflex is thus subcortical

In certain war neuroses of emotional origin in which the reflex is exaggerated jumping continues during sleep and deep hypnosis, although the patient does not hear the noise which induces it, even in a dream The afferent part of the reflex is thus subcortical That the reflex is quite independent of actual hearing is further shown by the fact that during deep hypnosis with the eyes open individuals in whom the reflex is normal or only slightly exaggerated do not always jump or blink and the pupils do not dilate even when a poker is banged against a shovel within a foot of the ear, although they answer even whispered questions and obey whispered commands, and the cutaneous and tendon reflexes remain unaffected Experiments on animals by Sherrington confirm these clinical observations and indicate that the auditory motor reflex is a function of the mid brain

A slight reflex was present in most of our cases of hysterical deafness, but it became less marked and sometimes disappeared completely or was confined to a slight dilatation of the pupil when the test was repeated A very nervous but totally deaf mute remained completely unmoved, never jumping or showing a flicker of his eyelid during one of the severest thunderstorms we have known and yet the next day he was completely cured by suggestion

It is thus clear that the presence of the auditory motor reflex does not imply that hearing occurs, and a man who says he can hear nothing but shows a normal reflex is not necessarily a malingerer, but may be suffering from genuine hysterical deafness or even organic deafness due to a bilateral lesion of the cortical auditory centres

4 *Persistence during sleep* —As hysterical symptoms are due to suggestion, it might be expected that they would not persist during sleep and Babinski regards this as a definite law Our experience agrees with his with regard to all other hysterical symptoms which we have investigated, such as paralysis, contractures, and anæsthesia, and we have seen several deaf mutes who talked in their sleep, but we have found that hysterical deafness, the behaviour of which during sleep does not appear to have been tested by Babinski, is an exception Thus, greatly to our surprise, we found it quite impossible to wake either of our two patients who were suffering from total hysterical deafness, by shouting or by making other very loud noises within a foot of their heads We convinced ourselves that deception was impossible, and the hysterical nature of the deafness in both cases was at a later date conclusively proved by their instantaneous recovery with powerful suggestion In one patient a slight twitch of the eyelids was sometimes observed with a particularly loud noise, but not in the other It seems probable that a malingerer could be detected by this test, as he would certainly wake if a loud noise was made when he was asleep, whereas in hysterical and organic deafness waking does not follow

5 *Effect of hypnosis* —We had expected that hearing would return in hysterical cases during hypnosis, but we found it quite impossible to make the patients obey any command or show any signs of hearing, and no reflex was produced, although both were deeply hypnotised on several occasions The synapses thus appear to remain unswitched during hypnosis as they do during sleep

6 *Change in the voice* —It is difficult to understand why there should be any difference in the effect on the voice of total organic deafness and total hysterical deafness, as the change is simply a result of the patient's inability to hear his own voice It is, however, a fact that we could not observe anything abnormal about the speech in any of our hysterical cases,

7 *Vestibular reaction* —We have found that the only test upon which absolute reliance can be placed in the diagnosis of hysterical deafness from organic deafness is the presence of normal vestibular reactions in the former and their loss in the latter The vestibular reactions are entirely beyond the control of the will, and it is therefore inconceivable that they should disappear as a result of suggestion As hysterical symptoms are always caused by suggestion, the vestibular reactions must remain unaffected in hysterical deafness This test has proved of great value in cases of total deafness But it must be remembered that in partial organic deafness the vestibular reactions are lost in the severer cases and exaggerated in the slighter cases, and the organic deafness may be accompanied and exaggerated by the simultaneous presence of hysterical deafness, which it is quite impossible to recognise except by the improvement which follows treatment by suggestion The vestibular reactions may be investigated by the rotation, caloric, or electric tests, in all of which nystagmus and giddiness occur in normal individuals, but not if the vestibular nerves are involved We have employed the rotation test for our cases the patient being tied into an arm chair, which is rotated ten times in 10 seconds

PATHOGENESIS

Hearing necessitates listening Inattention during a dull sermon results in total deafness to the sermon, and in hysterical deafness the patient is so convinced that he cannot hear that he does not listen. Although the sound vibrations reach the ear in the normal way they do not give rise to the slightest auditory sensation because of this inattention The synapses at one or more of the cell stations in the auditory path to the cerebral cortex must, therefore, be unswitched, probably as a result of retraction of the dendrons In absolute hysterical deafness the auditory motor reflex, which is a function of the mid brain, may be abolished, or greatly diminished One of the unswitched synapses must, therefore, be below the mid brain and either in the auditory nucleus or less probably in one of the intermediate cell stations—the superior olive or the nucleus of the lateral fillet

The persistence of the deafness during hypnosis and natural sleep shows that during the prolonged inattention of hysterical deafness which has lasted for a considerable period the unswitching of the synapses is more profound than that which normally occurs during deep sleep, in which the synapses can always be forced by a loud noise

TREATMENT

Deaf mutism

Uncomplicated deafness is the most difficult of all hysterical symptoms to treat, mutism is one of the easiest It is therefore fortunate that most cases of hysterical deafness are associated with mutism, as the return of speech in a deaf mute generally convinces him that he can also hear especially if he has been told that this will be the case He listens as soon as he finds he can speak, and the unswitched synapses are once more switched on

Among the numerous cases of deaf mutism observed by one of us (A. F H) rapid recovery always occurred, sometimes spontaneously as a result of various accidental circumstances and sometimes as a result of various methods of treatment One man was sleeping when his parents came to visit him a fortnight after he had become dumb as a result of shell shock They woke him up, and he at once said, "Hullo, mother" Another recovered after a cold douche as he was getting out of a hot bath. The majority of deaf mutes who required treatment were cured by the introduction of an intralaryngeal electrode, generally before the current was switched on after having been told that this would cure them at once With the aid of vigorous persuasion this method of suggestion is nearly always effective At least one man has recovered when drunk and numerous others under anæsthesia. Sufficient ether should be given to make the patient excited, and vigorous suggestion and persuasion must then be used until the patient has completely regained consciousness

Uncomplicated Deafness

We have only seen two cases of absolute hysterical deafness without mutism, and in one of them mutism was originally present, but spontaneous recovery had occurred some months earlier Both cases had had various forms of treatment before we saw them Simple encouragement and the promise of recovery had proved unavailing and when we repeated the promise to a man who was still completely deaf after eight months, he not unnaturally received our promise with considerable scepticism. We tried the effect of making very loud noises of different kinds near the patients ears in the hope that they might break through the resistance, and that when they were heard, re education with other sounds could be begun But this method which is sometimes successful in the partially deaf was unavailing as the deafness was absolute, and no noise, however loud, was heard. On many occasions the patients themselves shouted as loudly as they could through the chest-piece of a binaural stethoscope the ear piece of which was in their own ears and at other times the chest piece was put on an iron plate which was then hammered but they heard nothing Etherisation had been tried without success before we saw them. Various forms of suggestion were tried, one patient had a great belief in electricity but although we encouraged him to believe it would cure him it had no effect Both patients were hypnotised on a number of occasions without difficulty, but this proved useless as the deafness persisted and they could not be made to obey any commands which other hypnotised individuals obey immediately so that suggestions of recovery which are effective in patients suffering from incomplete hysterical deafness naturally gave no result, other loud noises and familiar tunes from a gramophone placed in contact with the ear during hypnosis had no more effect than shouting and as the deafness persisted during sleep it was impossible to cure the patients by suddenly exciting them during the night.

As all treatment had failed we told the more intelligent of the two patients that if he did not get well in the next week we would be compelled to advise him to undergo an operation which we had wished to avoid but which was quite certain to cure him. He was no better at the end of the week and was eager to have the operation He was given enough ether to make him excited and two small cuts were then made behind his ear, a hammer was banged on a sheet of iron during the "operation and the moment after the incision had been made the patient jumped off the table with his hearing restored The other patient was unwilling at first to undergo an operation but finally consented, as he was naturally impressed by the recovery of the first patient who was in the same ward and had been deaf for a much longer period The same 'operation was performed and complete recovery occurred in exactly the same way The joy shown by both patients on their recovery whilst in the theatre and on return to the ward was so obviously genuine that there could be no possible question about the genuineness of the deafness, at one time we had been rather doubtful about the second patient but fuller investigation had convinced us more than a fortnight before that he was not malingering

CONCLUSIONS

We are convinced from our experience in these cases that absolute deafness associated with normal vestibular reactions should be regarded as hysterical and when simple encouragement fails as will generally be the case if the patient is not also dumb an operation should be performed in the way we have described after the patient has been made to feel quite confident that it will restore his hearing

A Comparative Study

OF

THE REACTIONS TO HUMAN AND BOVINE TUBERCULIN APPLIED BY THE METHOD OF VON PIRQUET

IN CASES OF TUBERCULOUS DISEASE OF THE BONES AND JOINTS[1]

By H. J GAUVAIN, M A, B C CAMB, M R C S, L R C P LOND,

MEDICAL SUPERINTENDENT OF THE LORD MAYOR TRELOAR CRIPPLES HOSPITAL, ALTON HAMPSHIRE.

THE work here reported was done for the Local Government Board concurrently with their investigation into the types of tubercle bacilli occurring in tuberculous bones or joints[2]

In aid of the latter inquiry I sent for examination in the Board s Pathological Laboratory material from abscesses or sinuses occurring in 116 children[3] who were affected with tuberculous bone or joint disease and were patients in the Lord Mayor Treloar Cripples Hospital at Alton. In discussions which I had with the Board's pathologists, Dr A. Eastwood and Dr F Griffith, it occurred to us that, having these cases under observation, it would be a matter of interest and some practical importance to undertake a quantitative investigation of the von Pirquet cutaneous test on such of these patients as were available, to check the reactions by colour photographs and to endeavour to ascertain —

1 Whether the reaction to cutaneous inoculations of tuberculin was constantly present in patients suffering from undoubted tuberculous lesions of the bones or joints—that is in patients from whose lesions the tubercle bacilli had been isolated

2. If not constantly present under what circumstances the reaction would not appear

3 Whether by using both human and bovine tuberculin for the von Pirquet test it would be possible to ascertain, from the reaction which followed, whether the patient was suffering from tuberculosis of human or bovine origin

4 Whether the degree of reaction gave any indication of the severity of infection

5 The extent and nature of the reaction

These suggestions were submitted to the Board and received their approval Accordingly, with the aid of a grant from them, I carried out the proposed work during the autumn of 1914, with the assistance of Mrs Gauvain who took colour photographs of the reactions obtained

I applied the von Pirquet test to 80 out of the above 116 cases In order to avoid any risk of unconscious bias I made the inoculations and recorded their results without knowledge of bacteriological reports as to the type of bacillus found

The tuberculins employed were Koch s "old tuberculin' prepared from the human type of bacilli and his tuberculin prepared in identical way from bacilli of bovine origin These were supplied by Messrs Meister, Lucius and Bruning of 3 Jewry street E C who certified as to their purity and efficiency

Technique of Operation and Precautions Employed

The tuberculins were applied to suitable skin scarifications in dilutions of 1/64 1/16 1/4 and in full strength each in approximately equal bulk and controlled by inoculation of a scarification with the same quantity of sterile normal saline solution

In the majority of cases the scarifications were made on the anterior surfaces of both thighs where the legs were not available both arms were used In every case a minimum distance of at least two inches existed between

[3] In 11 of these cases tubercle bacilli were not obtained in culture of the [illegible] bacilli of "human" [illegible] "bovine" bacilli and 3 a[illegible] strains [illegible]

(*a*) Watch test for air conduction The distance a watch is heard (x) is expressed as a fraction of the distance at which it is heard by the normal ear (y) $\frac{x}{y}$

(*b*) Modified Schwabach test for bone conduction The base of a vibrating C tuning fork is held to the base of the mastoid whilst the other hand curtains the meatus The patient holds up his finger when the sound is no longer heard, the observer then transfers the tuning fork to his own normal mastoid and notes the number of additional seconds during which he hears the fork

These tests and comparison between bone and air conduction as in Rinne's test, are, however, only of value in the slighter cases, as in many instances deafness is absolute and no hearing is possible whether the sound is conducted by bone or through the air The vibration of a tuning fork held on the mastoid process is often felt and the aerial vibration caused by very loud noises is often appreciated, even when no sound is heard,

3 *Auditory motor or jump reflex*—A sudden noise normally causes an individual to jump and often to blink and the pupils dilate, the 'jump," at any rate, is a protective reflex and represents the preparation for flight or fight An officer whose left motor cortex had been almost completely destroyed went to *The Man who Stayed at Home* about four months after he was wounded His right arm jumped violently when the gun shot rang out on the stage, although no trace of voluntary movement returned until three months later The efferent part of the reflex is thus subcortical

In certain war neuroses of emotional origin in which the reflex is exaggerated jumping continues during sleep and deep hypnosis, although the patient does not hear the noise which induces it, even in a dream The afferent part of the reflex is thus subcortical That the reflex is quite independent of actual hearing is further shown by the fact that during deep hypnosis with the eyes open individuals in whom the reflex is normal or only slightly exaggerated do not always jump or blink and the pupils do not dilate even when a poker is banged against a shovel within a foot of the ear, although they answer even whispered questions and obey whispered commands, and the cutaneous and tendon reflexes remain unaffected Experiments on animals by Sherrington confirm these clinical observations and indicate that the auditory motor reflex is a function of the mid brain

A slight reflex was present in most of our cases of hysterical deafness, but it became less marked and some times disappeared completely or was confined to a slight dilatation of the pupil when the test was repeated A very nervous but totally deaf mute remained completely unmoved, never jumping or showing a flicker of his eyelid during one of the severest thunderstorms we have known and yet the next day he was completely cured by suggestion

It is thus clear that the presence of the auditory motor reflex does not imply that hearing occurs, and a man who says he can hear nothing but shows a normal reflex is not necessarily a malingerer, but may be suffering from genuine hysterical deafness or even organic deafness due to a bilateral lesion of the cortical auditory centres

4 *Persistence during sleep*—As hysterical symptoms are due to suggestion, it might be expected that they would not persist during sleep, and Babinski regards this as a definite law Our experience agrees with his with regard to all other hysterical symptoms which we have investigated, such as paralysis contractures, and anæsthesia, and we have seen several deaf mutes who talked in their sleep, but we have found that hysterical deafness, the behaviour of which during sleep does not appear to have been tested by Babinski, is an exception Thus, greatly to our surprise, we found it quite impossible to wake either of our two patients who were suffering from total hysterical deafness, by shouting or by making other very loud noises within a foot of their heads We convinced ourselves that deception was impossible, and the hysterical nature of the deafness in both cases was at a later date conclusively proved by their instantaneous recovery with powerful suggestion In one patient a slight twitch of the eyelids was sometimes observed with a particularly loud noise, but not in the other It seems probable that a malingerer could be detected by this test, as he would certainly wake if a loud noise was made when he was asleep, whereas in hysterical and organic deafness waking does not follow

5 *Effect of hypnosis*—We had expected that hearing would return in hysterical cases during hypnosis, but we found it quite impossible to make the patients obey any command or show any signs of hearing, and no reflex was produced, although both were deeply hypnotised on several occasions The synapses thus appear to remain unswitched during hypnosis as they do during sleep

6 *Change in the voice*—It is difficult to understand why there should be any difference in the effect on the voice of total organic deafness and total hysterical deafness, as the change is simply a result of the patient's inability to hear his own voice It is, however, a fact that we could not observe anything abnormal about the speech in any of our hysterical cases,

7 *Vestibular reaction*—We have found that the only test upon which absolute reliance can be placed in the diagnosis of hysterical deafness from organic deafness is the presence of normal vestibular reactions in the former and their loss in the latter The vestibular reactions are entirely beyond the control of the will, and it is therefore inconceivable that they should disappear as a result of suggestion As hysterical symptoms are always caused by suggestion, the vestibular reactions must remain unaffected in hysterical deafness This test has proved of great value in cases of total deafness But it must be remembered that in partial organic deafness the vestibular reactions are lost in the severer cases and exaggerated in the slighter cases, and the organic deafness may be accompanied and exaggerated by the simultaneous presence of hysterical deafness, which it is quite impossible to recognise except by the improvement which follows treatment by suggestion The vestibular reactions may be investigated by the rotation, caloric, or electric tests, in all of which nystagmus and giddiness occur in normal individuals, but not if the vestibular nerves are involved We have employed the rotation test for our cases, the patient being tied into an arm chair, which is rotated ten times in 10 seconds

PATHOGENESIS

Hearing necessitates listening Inattention during a dull sermon results in total deafness to the sermon, and in hysterical deafness the patient is so convinced that he cannot hear that he does not listen Although the sound vibrations reach the ear in the normal way, they do not give rise to the slightest auditory sensation because of this inattention The synapses at one or more of the cell stations in the auditory path to the cerebral cortex must, therefore, be unswitched, probably as a result of retraction of the dendrons In absolute hysterical deafness the auditory motor reflex, which is a function of the mid brain, may be abolished or greatly diminished One of the unswitched synapses must, therefore, be below the mid brain and either in the auditory nucleus or less probably in one of the intermediate cell stations—the superior olive or the nucleus of the lateral fillet

The persistence of the deafness during hypnosis and natural sleep shows that during the prolonged inattention of hysterical deafness which has lasted for a considerable period the unswitching of the synapses is more profound than that which normally occurs during deep sleep, in which the synapses can always be forced by a loud noise

TREATMENT

Deaf mutism

Uncomplicated deafness is the most difficult of all hysterical symptoms to treat, mutism is one of the easiest It is therefore fortunate that most cases of hysterical deafness are associated with mutism, as the return of speech in a deaf mute generally convinces him that he can also hear, especially if he has been told that this will be the case He listens as soon as he finds he can speak, and the unswitched synapses are once more switched on

Among the numerous cases of deaf mutism observed by one of us (A F H) rapid recovery always occurred, sometimes spontaneously as a result of various accidental circumstances and sometimes as a result of various methods of treatment One man was sleeping when his parents came to visit him a fortnight after he had become dumb as a result of shell shock. They woke him up and he at once said, "Hullo, mother " Another recovered after a cold douche as he was getting out of a hot bath The majority of deaf mutes who required treatment were cured by the introduction of an intralaryngeal electrode, generally before the current was switched on, after having been told that this would cure them at once With the aid of vigorous persuasion this method of suggestion is nearly always effective At least one man has recovered when drunk and numerous others under anæsthesia. Sufficient ether should be given to make the patient excited, and vigorous suggestion and persuasion must then be used until the patient has completely regained consciousness

Uncomplicated Deafness

We have only seen two cases of absolute hysterical deafness without mutism, and in one of them mutism was originally present, but spontaneous recovery had occurred some months earlier Both cases had had various forms of treatment before we saw them Simple encouragement and the promise of recovery had proved unavailing and when we repeated the promise to a man who was still completely deaf after eight months, he not unnaturally received our promise with considerable scepticism. We tried the effect of making very loud noises of different kinds near the patients' ears in the hope that they might break through the resistance, and that when they were heard re education with other sounds could be begun But this method which is sometimes successful in the partially deaf, was unavailing, as the deafness was absolute, and no noise, however loud, was heard On many occasions the patients themselves shouted as loudly as they could through the chest piece of a binaural stethoscope, the ear piece of which was in their own ears and at other times the chest piece was put on an iron plate which was then hammered, but they heard nothing Etherisation had been tried without success before we saw them Various forms of suggestion were tried, one patient had a great belief in electricity, but although we encouraged him to believe it would cure him, it had no effect Both patients were hypnotised on a number of occasions without difficulty, but this proved useless, as the deafness persisted and they could not be made to obey any commands which other hypnotised individuals obey immediately so that suggestions of recovery which are effective in patients suffering from incomplete hysterical deafness naturally gave no result, other loud noises and familiar tunes from a gramophone placed in contact with the ear during hypnosis had no more effect than shouting and as the deafness persisted during sleep it was impossible to cure the patients by suddenly exciting them during the night

As all treatment had failed, we told the more intelligent of the two patients that if he did not get well in the next week we would be compelled to advise him to undergo an operation which we had wished to avoid, but which was quite certain to cure him. He was no better at the end of the week and was eager to have the operation He was given enough ether to make him excited and two small cuts were then made behind his ear, a hammer was banged on a sheet of iron during the "operation ' and the moment after the incision had been made the patient jumped off the table with his hearing restored The other patient was unwilling at first to undergo an operation but finally consented, as he was naturally impressed by the recovery of the first patient, who was in the same ward and had been deaf for a much longer period The same operation was performed and complete recovery occurred in exactly the same way The joy shown by both patients on their recovery whilst in the theatre and on return to the ward was so obviously genuine that there could be no possible question about the genuineness of the deafness, at one time we had been rather doubtful about the second patient but fuller investigation had convinced us more than a fortnight before that he was not malingering

CONCLUSIONS

We are convinced from our experience in these cases that absolute deafness associated with normal vestibular reactions should be regarded as hysterical and when simple encouragement fails as will generally be the case if the patient is not also dumb an operation should be performed in the way we have described after the patient has been made to feel quite confident that it will restore his hearing

A Comparative Study
OF
THE REACTIONS TO HUMAN AND BOVINE TUBERCULIN APPLIED BY THE METHOD OF VON PIRQUET
IN CASES OF TUBERCULOUS DISEASE OF THE BONES AND JOINTS [1]

BY H. J GAUVAIN, M A, B C CAMB,
M R C S, L R C P LOND,
MEDICAL SUPERINTENDENT OF THE LORD MAYOR TRELOAR CRIPPLES HOSPITAL, ALTON HAMPSHIRE.

THE work here reported was done for the Local Government Board concurrently with their investigation into the types of tubercle bacilli occurring in tuberculous bones or joints [2]

In aid of the latter inquiry I sent for examination in the Board s Pathological Laboratory material from abscesses or sinuses occurring in 116 children [3] who were affected with tuberculous bone or joint disease and were patients in the Lord Mayor Treloar Cripples' Hospital at Alton In discussions which I had with the Board's pathologists, Dr A Eastwood and Dr F Griffith, it occurred to us that, having these cases under observation, it would be a matter of interest and some practical importance to undertake a quantitative investigation of the von Pirquet cutaneous test on such of these patients as were available, to check the reactions by colour photographs and to endeavour to ascertain —

1. Whether the reaction to cutaneous inoculations of tuberculin was constantly present in patients suffering from undoubted tuberculous lesions of the bones or joints—that is in patients from whose lesions the tubercle bacilli had been isolated
2. If not constantly present, under what circumstances the reaction would not appear
3. Whether by using both human and bovine tuberculin for the von Pirquet test it would be possible to ascertain, from the reaction which followed, whether the patient was suffering from tuberculosis of human or bovine origin
4. Whether the degree of reaction gave any indication of the severity of infection
5. The extent and nature of the reaction

These suggestions were submitted to the Board and received their approval Accordingly with the aid of a grant from them, I carried out the proposed work during the autumn of 1914, with the assistance of Mrs Gauvain, who took colour photographs of the reactions obtained

I applied the von Pirquet test to 80 out of the above 116 cases In order to avoid any risk of unconscious bias I made the inoculations and recorded their results without knowledge of bacteriological reports as to the type of bacillus found

The tuberculins employed were Koch s "old tuberculin ' prepared from the human' type of bacilli, and his tuberculin prepared in identical way from bacilli of bovine origin These were supplied by Messrs Meister Lucius, and Bruning of 3 Jewry street E C, who certified as to their purity and efficiency

Technique of Operation and Precautions Employed

The tuberculins were applied to suitable skin scarifications in dilutions of 1 64 1 16 1 4 and in full strength each in approximately equal bulk and controlled by inoculation of a scarification with the same quantity of sterile normal saline solution

[3] In 11 of these cases tubercle bacilli were not obtained in culture of the rest 70 yielded bacilli of human type 32 bovine " bacilli and 3 atypical strains of tubercle bacilli

(*a*) Watch test for air conduction The distance a watch is heard (x) is expressed as a fraction of the distance at which it is heard by the normal ear (y) $\frac{x}{y}$

(*b*) Modified Schwabach test for bone conduction The base of a vibrating C tuning fork is held to the base of the mastoid whilst the other hand curtains the meatus The patient holds up his finger when the sound is no longer heard, the observer then transfers the tuning fork to his own normal mastoid and notes the number of additional seconds during which he hears the fork

These tests and comparison between bone and air conduction, as in Rinne's test, are, however, only of value in the slighter cases, as in many instances deafness is absolute and no hearing is possible whether the sound is conducted by bone or through the air The vibration of a tuning fork held on the mastoid process is often felt and the aerial vibration caused by very loud noises is often appreciated, even when no sound is heard,

3 *Auditory motor or jump reflex*—A sudden noise normally causes an individual to jump and often to blink and the pupils dilate, the "jump," at any rate, is a protective reflex and represents the preparation for flight or fight An officer whose left motor cortex had been almost completely destroyed went to *The Man who Stayed at Home* about four months after he was wounded His right arm jumped violently when the gun shot rang out on the stage, although no trace of voluntary movement returned until three months later The efferent part of the reflex is thus subcortical

In certain war neuroses of emotional origin in which the reflex is exaggerated jumping continues during sleep and deep hypnosis, although the patient does not hear the noise which induces it, even in a dream The afferent part of the reflex is thus subcortical That the reflex is quite independent of actual hearing is further shown by the fact that during deep hypnosis with the eyes open individuals in whom the reflex is normal or only slightly exaggerated do not always jump or blink and the pupils do not dilate even when a poker is banged against a shovel within a foot of the ear, although they answer even whispered questions and obey whispered commands, and the cutaneous and tendon reflexes remain unaffected Experiments on animals by Sherrington confirm these clinical observations and indicate that the auditory motor reflex is a function of the mid brain

A slight reflex was present in most of our cases of hysterical deafness, but it became less marked and sometimes disappeared completely or was confined to a slight dilatation of the pupil when the test was repeated A very nervous but totally deaf mute remained completely unmoved, never jumping or showing a flicker of his eyelid during one of the severest thunderstorms we have known and yet the next day he was completely cured by suggestion

It is thus clear that the presence of the auditory motor reflex does not imply that hearing occurs, and a man who says he can hear nothing but shows a normal reflex is not necessarily a malingerer, but may be suffering from genuine hysterical deafness or even organic deafness due to a bilateral lesion of the cortical auditory centres

4 *Persistence during sleep*—As hysterical symptoms are due to suggestion, it might be expected that they would not persist during sleep and Babinski regards this as a definite law Our experience agrees with his with regard to all other hysterical symptoms which we have investigated, such as paralysis, contractures, and anæsthesia, and we have seen several deaf mutes who talked in their sleep, but we have found that hysterical deafness, the behaviour of which during sleep does not appear to have been tested by Babinski, is an exception Thus, greatly to our surprise, we found it quite impossible to wake either of our two patients, who were suffering from total hysterical deafness, by shouting or by making other very loud noises within a foot of their heads We convinced ourselves that deception was impossible and the hysterical nature of the deafness in both cases was at a later date conclusively proved by their instantaneous recovery with powerful suggestion In one patient a slight twitch of the eyelids was sometimes observed with a particularly loud noise, but not in the other It seems probable that a malingerer could be detected by this test, as he would certainly wake if a loud noise was made when he was asleep, whereas in hysterical and organic deafness waking does not follow

5 *Effect of hypnosis*—We had expected that hearing would return in hysterical cases during hypnosis, but we found it quite impossible to make the patients obey any command or show any signs of hearing, and no reflex was produced, although both were deeply hypnotised on several occasions The synapses thus appear to remain unswitched during hypnosis as they do during sleep

6 *Change in the voice*—It is difficult to understand why there should be any difference in the effect on the voice of total organic deafness and total hysterical deafness, as the change is simply a result of the patient's inability to hear his own voice It is, however, a fact that we could not observe anything abnormal about the speech in any of our hysterical cases,

7 *Vestibular reaction*—We have found that the only test upon which absolute reliance can be placed in the diagnosis of hysterical deafness from organic deafness is the presence of normal vestibular reactions in the former and their loss in the latter The vestibular reactions are entirely beyond the control of the will, and it is therefore inconceivable that they should disappear as a result of suggestion As hysterical symptoms are always caused by suggestion, the vestibular reactions must remain unaffected in hysterical deafness This test has proved of great value in cases of total deafness But it must be remembered that in partial organic deafness the vestibular reactions are lost in the severer cases and exaggerated in the slighter cases, and the organic deafness may be accompanied and exaggerated by the simultaneous presence of hysterical deafness, which it is quite impossible to recognise except by the improvement which follows treatment by suggestion The vestibular reactions may be investigated by the rotation, caloric, or electric tests, in all of which nystagmus and giddiness occur in normal individuals, but not if the vestibular nerves are involved We have employed the rotation test for our cases, the patient being tied into an arm chair, which is rotated ten times in 10 seconds

PATHOGENESIS

Hearing necessitates listening Inattention during a dull sermon results in total deafness to the sermon, and in hysterical deafness the patient is so convinced that he cannot hear that he does not listen Although the sound vibrations reach the ear in the normal way, they do not give rise to the slightest auditory sensation because of this inattention The synapses at one or more of the cell stations in the auditory path to the cerebral cortex must, therefore, be unswitched, probably as a result of retraction of the dendrons In absolute hysterical deafness the auditory motor reflex, which is a function of the mid brain may be abolished, or greatly diminished One of the unswitched synapses must, therefore, be below the mid brain and either in the auditory nucleus or less probably in one of the intermediate cell stations—the superior olive or the nucleus of the lateral fillet

The persistence of the deafness during hypnosis and natural sleep shows that during the prolonged inattention of hysterical deafness which has lasted for a considerable period the unswitching of the synapses is more profound than that which normally occurs during deep sleep, in which the synapses can always be forced by a loud noise

TREATMENT

Deaf mutism

Uncomplicated deafness is the most difficult of all hysterical symptoms to treat, mutism is one of the easiest It is therefore fortunate that most cases of hysterical deafness are associated with mutism, as the return of speech in a deaf mute generally convinces him that he can also hear, especially if he has been told that this will be the case He listens as soon as he finds he can speak, and the unswitched synapses are once more switched on

Among the numerous cases of deaf mutism observed by one of us (A. F H) rapid recovery always occurred, sometimes spontaneously as a result of various accidental circumstances and sometimes as a result of various methods of treatment One man was sleeping when his parents came to visit him a fortnight after he had become dumb as a result of shell shock. They woke him up, and he at once said, "Hullo, 1914 The next morning the patient looked ill, the eyes were sunken, face drawn and flushed, and the child was very quiet There was slight erythema on the chest, abdomen, and back, the temperature was 100 5°F, and the patient complained of feeling ill and having headache At 3 P M the temperature was 103 4°, cheeks more flushed, headache intense, and patient drowsy In the evening the temperature went down, the headache was relieved, and the rash disappeared The patient slept well at night and the next morning he was bright, lively, with no headache and no discomfort, his temperature was normal and he appeared quite well

In this patient the local reaction was more intense than in any of the others in the whole series He was a fair skinned, red haired boy It is probable that these symptoms were not the result of the test but due to other and unascertained causes This was the only case in which the general reaction could be called severe

In the remaining three cases a temperature rising to 100° F was alone noted In no case did the general reaction extend beyond the day following the inoculation

It should be remembered that the patients tested were children and not able to describe symptoms clearly, but they were kept in bed under close observation and no evidence could be found of general reaction more intense than stated above

In no cases were any ill effects observed other than the transient ones exceptionally occurring and already recorded and these apparently need not be anticipated if not commencing within 24 hours of the inoculation

Local Reactions to Human and Bovine Tuberculin

The local reactions to human and bovine tuberculin were found to be essentially similar, and, without the knowledge that the one tuberculin was always inoculated on the right side and the other on the left, it would have been impossible to decide whether any one reaction was due to human or bovine tuberculin

While variations in the degree of the local reactions between one patient and another were frequently marked, it was the exception to find considerable variation in degree between the reactions to human and bovine tuberculin in any one patient Out of the 80 cases investigated in 23 the reactions to human and bovine tuberculin were so nearly equal that it was impossible to decide which was the greater In 21 cases the reaction to human tuberculin was slightly greater than to bovine In 25 cases the reaction to bovine tuberculin was slightly more marked than to human. In four cases the reaction to human tuberculin was markedly greater than to bovine In seven cases the bovine reaction was markedly greater than the human (see Table)

Comparison of Results obtained by Von Pirquet Test with Bacteriological Findings

Reactions	No of cases	Bacteriological findings			
		Human	Bovine	Atypical	Negative
Approximately equal	23	16	5	1	1
Slightly greater to human tuberculin	21	13	8	—	—
Slightly greater to bovine tuberculin	25	14	6	1	4
Markedly greater to human tuberculin	4	2	1	—	1
Markedly greater to bovine tuberculin	7	5	2	—	—
Totals -	80	50	22	2	6

Relation of Degree of Reaction and Severity of Disease

No definite relationship could be established between the degree of the reaction and the severity of the disease

Thus G D No 1 suffering from severe dorso-lumbar caries with sinuses reacted but feebly while L G, No 60 suffering from an approximately similar condition, reacted well

G L No 50 suffering from very severe tuberculous disease of both hip-joints with a sinus in connexion with the right hip reacted very feebly, but M B No 9 suffering from similar lesions of almost equal severity reacted intensely

Again G P No 58, suffering from tuberculous disease of the knee joint of moderate severity, reacted well but H M No 62 suffering from a similar but much more severe lesion, reacted feebly And similarly with other cases

I have formed the impression that patients who are weakly and cachectic irrespective of the severity of the local lesions tend to react feebly whereas patients who are strong and vigorous whether their local lesions be severe or slight, may show either an intense or mild reaction to the von Pirquet test

Progressive disappearance of the reaction from the 1/64 scar upwards did not indicate diminished activity of the disease No guide to prognosis could be found by comparing the reactions produced by the weaker and the stronger applications of tuberculin in the same patient

Since this investigation was undertaken a sufficient interval has elapsed to estimate with some degree of accuracy the prognostic value of the quantitative von Pirquet test As might be anticipated, the weakly and cachectic patients have not made such substantial or rapid progress towards recovery as the strong and vigorous ones Yet the reactions obtained in the latter were more intense than those in the former Where weak solutions as well as concentrated solutions give marked reactions the only inference which I could draw was that the patient had abundant reacting power

One of the most marked reactions to all strengths of tuberculin, both human and bovine, occurred in a strong, vigorous and well nourished girl apparently in robust health but with a bad tuberculous family history, and who had been long exposed to danger of infection In this patient I could detect no clinical or radiographic evidence of disease, though, doubtless she was infected

On the other hand, patients with severe lesions with progressive disease often reacted feebly The reaction to inoculation was therefore rather a measure of the degree of resistance of the patient than of the severity of the infection

Results of Investigation

The final result of the investigation may be stated briefly as follows —

1 Local reactions to inoculations of both human and bovine tuberculin were invariably present in all patients from whose pus tubercle bacilli had been isolated

2 Though reactions were invariably present the degree of reaction varied within wide limits

3 Weakly and cachectic patients usually reacted feebly quite irrespective of differences in the severity of their local lesions

4 Strong and vigorous patients exhibited wide differences in the degree of their reactions, irrespective of differences in the extent or the severity of their local lesions

5 The quantitative von Pirquet test was not found to be of value in forming an estimate of the severity of the infection, and was of little prognostic value

6 It was impossible to differentiate the type of tubercle bacillus with which the patient was attacked by the nature of the reaction to the tuberculin employed

To the Honorary Medical Board of this hospital I wish to record my thanks for so readily consenting to this investigation being undertaken and for much encouragement given and interest displayed in the progress of the research

I desire to express my grateful thanks for invaluable assistance afforded by Dr Eastwood, both in suggesting the most useful lines on which this investigation should proceed and in giving material and helpful criticism on the interpretation of the observations made To my wife I am also deeply indebted for the colour photographs she took of the reactions produced, which form a permanent record of great value and afforded a useful check and supplement to direct observations made at the bedside

---

A SERVICE OF MUNICIPAL MIDWIVES FOR CHELMSFORD —In consequence of having to look after the practices of colleagues on war service the remaining doctors in Chelmsford have notified to the medical officer of health their inability to attend maternity cases The circumstances were brought before the town council by the medical officer of health as a matter of urgency and attention was drawn to the difficulties likely to arise in the town with its annual total of births between 400 and 500 Only three certified midwives are working in the borough and the remaining medical men suggested that the difficulty should be solved by the appointment on the part of the council of two certified midwives to assist the local medical service The Local Government Board had assented to the suggestion and agreed to pay one half of the cost incurred by the council After discussion *in camera* the council authorised the medical officer of health to select two midwives at a minimum salary of £75 each on the understanding that the arrangement was to last only for the duration of the war and three months after any one scarification and its nearest fellow, so that adjacent reactions should not become confluent

To minimise the possibility of tuberculin applied to one scarification being conveyed by the lymphatic channels to a neighbouring scarification which had been treated with a weaker solution of tuberculin the solutions, commencing with the control, were applied to the scarifications in order of increasing strength from the distal to the proximal extremity of each limb

Human tuberculin was always applied to scarifications on the right side of the body and bovine tuberculin to scarifications on the left side

To ensure the scarifications being as nearly as possible equal, the same von Pirquet scarifier, supplied by Messrs Allen and Hanburys, was in every case used This instrument may be quickly and conveniently sterilised by passing through the flame

The control solution and the tuberculins were all applied to the scarification marks with sterile glass eye-rods of the same size, a separate rod being kept in each bottle In this way approximately the same quantity of liquid was applied to the centre of each scar The solution was simply placed on the scar, not rubbed in

The bottles containing the solutions of tuberculin were all placed on one tray in ascending order of strength On the right-hand side of the tray was the human tuberculin, on the left the bovine In the middle was the bottle containing the control solution The bottles had distinguishing coloured labels as a further safeguard against the possibility of introducing the wrong solution into the various scarifications

The test was conducted as follows —

The scarifier was first sterilised in the flame and the skin over the area on both limbs to be scarified cleansed with ether The tip of the scarifier was then placed on the skin, the instrument being held vertically, and the scarification was performed by the exercise of firm but gentle pressure while rotating the scarifier between the finger and thumb about half a-dozen times The outer layer of the skin over a minute circular area was thus removed and the vascular subcuticular layer brought to view It was found quite unnecessary to continue the pressure long enough to cause any bleeding

The five scarifications were thus rapidly made on each of the two selected limbs at approximately the same level on both sides and in the same situation The control saline was then applied to each of the most distal scarifications, the human tuberculin in increasing strength to the succeeding scarifications up the right side, the bovine similarly up the left The limbs were kept uncovered until the liquid applied had dried No dressing was employed, and the limbs, when dry, were simply covered with bedclothes in the ordinary way

Local Reactions

In no case did either variety of tuberculin fail to react The degree and extent of the reaction varied within wide limits, and its persistence was also variable, but the response of every case to both tuberculins was particularly noteworthy In the majority of cases reaction was clearly visible within 24 hours, and often could be observed within 12 hours It usually reached its maximum at between 36 and 48 hours, and then gradually faded Frequently the reaction of the quarter and full strength tuberculins remained well marked for a week or longer In exceptional cases the reaction persisted for a month or more and in one case (E M, No 89) who was inoculated on Nov 26th, 1914, the reaction was still clearly visible on March 11th, 1915

In each case the controls were negative After two or three days the scars which had received the control solution became invisible except on close search

At this period even when no definite reaction could be distinguished in the scarifications treated with the lower two dilutions of the tuberculin, the scars made would usually persist Sometimes though no colour change round these scars could be seen, passage of the finger over the scars gave the sensation of a small but definite papule depressed in the centre

In patients not the subject of tuberculous disease this retardation of healing of the scar, to which diluted tuberculin had been applied, did not appear to exist This observation was only made on a few subjects as suitable non tuberculous subjects of the age of the patients tested were not readily available If however, this observation stands the test of further investigation it would afford the suggestion that delayed healing in a scar to which diluted tuberculin had been applied even in the absence of colour change and without palpable raising of the edge of the scar, is in itself evidence of a minimum degree of a positive reaction to the von Pirquet test

Next in order of intensity were the reactions where there appeared a circumferential reddening of the skin about the crateriform depression made by the scarifier, this reddening varied from the merest line in some cases to a total circumference of about an inch or more in others The outer edge of this area was quite distinct and the colour was of almost equal intensity, though perhaps not quite so marked at the periphery The shape was sometimes irregular, but more usually circular or somewhat oval

In reactions of greater severity than the last an outer halo of faintly red discolouration was distinctly visible, much less intense than the inner red area and of varying size, though rarely extending for more than a quarter of an inch from the central denser area, except where it tapered out into a filamentous projection or projections which marked the radiation of a lymphatic channel

Finally, when the reaction was most intense the marked red area immediately about the scar became paler and more livid adjacent to the crater and sometimes assumed a purplish hue This appearance marked the maximum reaction noted It was characterised by four distinct zones —a depressed scar in the centre, bordering this a livid pink or purplish zone, surrounding the latter a well marked zone of intense redness, and, embracing the last, a faintly pinkish area, the outer limit of which was indefinite and merged into the surrounding skin, being sometimes prolonged for a shorter or longer distance into radiating lymphatics

As was to be expected, the degree of reaction generally varied with the strength of solution of tuberculin, stronger solutions provoking a more intense reaction than weaker In some cases, however, particularly when inoculations were made on the thighs, the difference between reactions of a quarter and full strength were not marked, and occasionally the quarter strength solution appeared to cause a more intense reaction than the full strength This may possibly be partly accounted for by accidental inequality in the degree of scarification It was found that on approaching the groin the skin was less tense and rested on a less firm foundation than on the middle region of the thigh With equal pressure the scar made by the scarifier in the groin region did not penetrate so deeply in the looser skin as the scar made on the firmer skin in the middle of the thigh

Hence it is conceivably possible that a weaker solution of tuberculin inoculated into the skin of the middle of the thigh might cause a greater reaction than a stronger solution inoculated into the skin of the groin

General Reaction

To ascertain if any general reaction followed the employment of this test the temperature in each of the cases investigated was taken every two hours for the first 48 hours and every four hours for the succeeding 48 hours, subsequently the usual morning and evening temperatures were alone taken, unless for any reason it was found desirable to take the temperature more frequently Subjective symptoms were also very carefully noted

In the great majority of cases, except for a fractional rise of temperature there was no evidence of any general reaction whatever Often not even a slight rise of temperature was observed [4]

In six cases only did the temperature rise up to or above 100° F where the raised temperature could be ascribed to the test This rise was always on the day succeeding the inoculation In three of these cases the patients complained of headache and general malaise These symptoms always rapidly disappeared and in only one case did the headache persist throughout the day following the inoculation

General reaction, when present, was only noticeable on the day succeeding the application of the test

In one (R T No 74) of these six the temperature rose to 100° F on the afternoon succeeding the day of inoculation, and the patient complained of slight headache

In another case (N R, No 80) the temperature rose to 101 4° F on the afternoon following the day of inoculation Patient looked flushed complained of headache, and vomited undigested food once

In the case where the general reaction was most marked (M B, No 9) the test was applied at 7 P M on August 26th,

---

[4] Care was taken where possible to test only apyrexial patients In very few cases was there any pyrexia due to complicating sepsis or other cause

1914 The next morning the patient looked ill the eyes were sunken, face drawn and flushed, and the child was very quiet There was slight erythema on the chest, abdomen and back, the temperature was 100·5° F, and the patient complained of feeling ill and having headache At 3 P M the temperature was 103·4°, cheeks more flushed, headache intense, and patient drowsy In the evening the temperature went down the headache was relieved, and the rash disappeared The patient slept well at night and the next morning he was bright lively, with no headache and no discomfort, his temperature was normal and he appeared quite well

In this patient the local reaction was more intense than in any of the others in the whole series He was a fair skinned red haired boy It is probable that these symptoms were not the result of the test but due to other and unascertained causes This was the only case in which the general reaction could be called severe

In the remaining three cases a temperature rising to 100° F was alone noted In no case did the general reaction extend beyond the day following the inoculation

It should be remembered that the patients tested were children and not able to describe symptoms clearly, but they were kept in bed under close observation and no evidence could be found of general reaction more intense than stated above

In no cases were any ill effects observed other than the transient ones exceptionally occurring and already recorded and these apparently need not be anticipated if not commencing within 24 hours of the inoculation

Local Reactions to Human and Bovine Tuberculin

The local reactions to human and bovine tuberculin were found to be essentially similar, and, without the knowledge that the one tuberculin was always inoculated on the right side and the other on the left it would have been impossible to decide whether any one reaction was due to human or bovine tuberculin

While variations in the degree of the local reactions between one patient and another were frequently marked, it was the exception to find considerable variation in degree between the reactions to human and bovine tuberculin in any one patient Out of the 80 cases investigated in 23 the reactions to human and bovine tuberculin were so nearly equal that it was impossible to decide which was the greater In 21 cases the reaction to human tuberculin was slightly greater than to bovine In 25 cases the reaction to bovine tuberculin was slightly more marked than to human In four cases the reaction to human tuberculin was markedly greater than to bovine In seven cases the bovine reaction was markedly greater than the human. (see Table)

Comparison of Results obtained by Von Pirquet Test with Bacteriological Findings

Reactions	No of cases	Bacteriological findings			
		Human	Bovine	Atypical	Negative
Approximately equal	23	16	5	1	1
Slightly greater to human tuberculin	21	13	8	—	—
Slightly greater to bovine tuberculin	25	14	6	1	4
Markedly greater to human tuberculin	[illegible]	2	1	—	1
Markedly greater to bovine tuberculin	7	5	2	—	—
Totals	80	50	22	2	6

Relation of Degree of Reaction and Severity of Disease

No definite relationship could be established between the degree of the reaction and the severity of the disease

Thus C D No 1, suffering from severe dorso-lumbar caries with sinuses reacted but feebly while L G No 60 suffering from an approximately similar condition reacted well

G L. No 50 suffering from very severe tuberculous disease of both hip joints with a sinus in connexion with the right hip reacted very feebly but M B., No 9 suffering from similar lesions of almost equal severity, reacted intensely

Again G P No 58 suffering from tuberculous disease of the knee joint of moderate severity reacted well but H M No 62, suffering from a similar but much more severe lesion, reacted feebly And similarly with other cases

I have formed the impression that patients who are weakly and cachectic irrespective of the severity of the local lesions tend to react feebly whereas patients who are strong and vigorous whether their local lesions be severe or slight, may show either an intense or mild reaction to the von Pirquet test

Progressive disappearance of the reaction from the 1/64 scar upwards did not indicate diminished activity of the disease No guide to prognosis could be found by comparing the reactions produced by the weaker and the stronger applications of tuberculin in the same patient

Since this investigation was undertaken a sufficient interval has elapsed to estimate with some degree of accuracy the prognostic value of the quantitative von Pirquet test As might be anticipated, the weakly and cachectic patients have not made such substantial or rapid progress towards recovery as the strong and vigorous ones Yet the reactions obtained in the latter were more intense than those in the former Where weak solutions as well as concentrated solutions give marked reactions the only inference which I could draw was that the patient had abundant reacting power

One of the most marked reactions to all strengths of tuberculin, both human and bovine, occurred in a strong vigorous, and well nourished girl apparently in robust health but with a bad tuberculous family history, and who had been long exposed to danger of infection In this patient I could detect no clinical or radiographic evidence of disease, though doubtless she was infected

On the other hand patients with severe lesions with progressive disease often reacted feebly The reaction to inoculation was therefore rather a measure of the degree of resistance of the patient than of the severity of the infection

Results of Investigation

The final result of the investigation may be stated briefly as follows —

1 Local reactions to inoculations of both human and bovine tuberculin were invariably present in all patients from whose pus tubercle bacilli had been isolated

2 Though reactions were invariably present the degree of reaction varied within wide limits

3 Weakly and cachectic patients usually reacted feebly quite irrespective of differences in the severity of their local lesions

4 Strong and vigorous patients exhibited wide differences in the degree of their reactions irrespective of differences in the extent or the severity of their local lesions

5 The quantitative von Pirquet test was not found to be of value in forming an estimate of the severity of the infection and was of little prognostic value

6 It was impossible to differentiate the type of tubercle bacillus with which the patient was attacked by the nature of the reaction to the tuberculin employed

To the Honorary Medical Board of this hospital I wish to record my thanks for so readily consenting to this investigation being undertaken and for much encouragement given and interest displayed in the progress of the research

I desire to express my grateful thanks for invaluable assistance afforded by Dr Eastwood, both in suggesting the most useful lines on which this investigation should proceed and in giving material and helpful criticism on the interpretation of the observations made To my wife I am also deeply indebted for the colour photographs she took of the reactions produced which form a permanent record of great value and afforded a useful check and supplement to direct observations made at the bedside

---

A SERVICE OF MUNICIPAL MIDWIVES FOR CHELMSFORD —In consequence of having to look after the practices of colleagues on war service the remaining doctors in Chelmsford have notified to the medical officer of health their inability to attend maternity cases The circumstances were brought before the town council by the medical officer of health as a matter of urgency and attention was drawn to the difficulties likely to arise in the town with its annual total of births between 400 and 500 Only three certified midwives are working in the borough and the remaining medical men suggested that the difficulty should be solved by the appointment on the part of the council of two certified midwives to assist the local medical service The Local Government Board had assented to the suggestion and agreed to pay one half of the cost incurred by the council After discussion *in camera* the council authorised the medical officer of health to select two midwives at a minimum salary of £75 each on the understanding that the arrangement was to last only for the duration of the war and three months after any one scarification and its nearest fellow, so that adjacent reactions should not become confluent

To minimise the possibility of tuberculin applied to one scarification being conveyed by the lymphatic channels to a neighbouring scarification which had been treated with a weaker solution of tuberculin the solutions, commencing with the control, were applied to the scarifications in order of increasing strength from the distal to the proximal extremity of each limb

Human tuberculin was always applied to scarifications on the right side of the body and bovine tuberculin to scarifications on the left side

To ensure the scarifications being as nearly as possible equal, the same von Pirquet scarifier, supplied by Messrs Allen and Hanburys, was in every case used This instrument may be quickly and conveniently sterilised by passing through the flame

The control solution and the tuberculins were all applied to the scarification marks with sterile glass eye-rods of the same size, a separate rod being kept in each bottle In this way approximately the same quantity of liquid was applied to the centre of each scar The solution was simply placed on the scar, not rubbed in

The bottles containing the solutions of tuberculin were all placed on one tray in ascending order of strength On the right-hand side of the tray was the human tuberculin, on the left the bovine In the middle was the bottle containing the control solution The bottles had distinguishing coloured labels as a further safeguard against the possibility of introducing the wrong solution into the various scarifications

The test was conducted as follows —

The scarifier was first sterilised in the flame and the skin over the area on both limbs to be scarified cleansed with ether The tip of the scarifier was then placed on the skin, the instrument being held vertically, and the scarification was performed by the exercise of firm but gentle pressure while rotating the scarifier between the finger and thumb about half a-dozen times The outer layer of the skin over a minute circular area was thus removed and the vascular subcuticular layer brought to view It was found quite unnecessary to continue the pressure long enough to cause any bleeding

The five scarifications were thus rapidly made on each of the two selected limbs at approximately the same level on both sides and in the same situation The control saline was then applied to each of the most distal scarifications, the human tuberculin in increasing strength to the succeeding scarifications up the right side, the bovine similarly up the left The limbs were kept uncovered until the liquid applied had dried No dressing was employed, and the limbs, when dry, were simply covered with bedclothes in the ordinary way

Local Reaction

In no case did either variety of tuberculin fail to react The degree and extent of the reaction varied within wide limits, and its persistence was also variable, but the response of every case to both tuberculins was particularly noteworthy In the majority of cases reaction was clearly visible within 24 hours, and often could be observed within 12 hours It usually reached its maximum at between 36 and 48 hours, and then gradually faded Frequently the reaction of the quarter and full strength tuberculins remained well marked for a week or longer In exceptional cases the reaction persisted for a month or more, and in one case (E M, No 89) who was inoculated on Nov 26th, 1914, the reaction was still clearly visible on March 11th, 1915

In each case the controls were negative After two or three days the scars which had received the control solution became invisible except on close search

At this period even when no definite reaction could be distinguished in the scarifications treated with the lower two dilutions of the tuberculin, the scars made would usually persist Sometimes, though no colour change round these scars could be seen, passage of the finger over the scars gave the sensation of a small but definite papule depressed in the centre

In patients not the subject of tuberculous disease this retardation of healing of the scar, to which diluted tuberculin had been applied, did not appear to exist. This observation was only made on a few subjects as suitable non tuberculous subjects of the age of the patients tested were not readily available If however, this observation stands the test of further investigation it would afford the suggestion that delayed healing in a scar to which diluted tuberculin had been applied even in the absence of colour change and without palpable raising of the edge of the scar, is in itself evidence of a minimum degree of a positive reaction to the von Pirquet test

Next in order of intensity were the reactions where there appeared a circumferential reddening of the skin about the crateriform depression made by the scarifier, this reddening varied from the merest line in some cases to a total circumference of about an inch or more in others The outer edge of this area was quite distinct and the colour was of almost equal intensity, though perhaps not quite so marked at the periphery The shape was sometimes irregular, but more usually circular or somewhat oval

In reactions of greater severity than the last an outer halo of faintly red discolouration was distinctly visible, much less intense than the inner red area and of varying size, though rarely extending for more than a quarter of an inch from the central denser area, except where it tapered out into a filamentous projection or projections which marked the radiation of a lymphatic channel

Finally, when the reaction was most intense the marked red area immediately about the scar became paler and more livid adjacent to the crater and sometimes assumed a purplish hue This appearance marked the maximum reaction noted It was characterised by four distinct zones —a depressed scar in the centre, bordering this a livid pink or purplish zone, surrounding the latter a well marked zone of intense redness, and, embracing the last, a faintly pinkish area, the outer limit of which was indefinite and merged into the surrounding skin, being sometimes prolonged for a shorter or longer distance into radiating lymphatics

As was to be expected, the degree of reaction generally varied with the strength of solution of tuberculin, stronger solutions provoking a more intense reaction than weaker In some cases, however, particularly when inoculations were made on the thighs the difference between reactions of a quarter and full strength were not marked, and occasionally the quarter strength solution appeared to cause a more intense reaction than the full strength This may possibly be partly accounted for by accidental inequality in the degree of scarification It was found that on approaching the groin the skin was less tense and rested on a less firm foundation than on the middle region of the thigh With equal pressure the scar made by the scarifier in the groin region did not penetrate so deeply in the looser skin as the scar made on the firmer skin in the middle of the thigh

Hence it is conceivably possible that a weaker solution of tuberculin inoculated into the skin of the middle of the thigh might cause a greater reaction than a stronger solution inoculated into the skin of the groin

General Reaction

To ascertain if any general reaction followed the employment of this test the temperature in each of the cases investigated was taken every two hours for the first 48 hours and every four hours for the succeeding 48 hours, subsequently the usual morning and evening temperatures were alone taken, unless for any reason it was found desirable to take the temperature more frequently Subjective symptoms were also very carefully noted

In the great majority of cases, except for a fractional rise of temperature, there was no evidence of any general reaction whatever Often not even a slight rise of temperature was observed [4]

In six cases only did the temperature rise up to or above 100° F where the raised temperature could be ascribed to the test This rise was always on the day succeeding the inoculation In three of these cases the patients complained of headache and general malaise These symptoms always rapidly disappeared and in only one case did the headache persist throughout the day following the inoculation

General reaction, when present was only noticeable on the day succeeding the application of the test

In one (R T No 74) of these six the temperature rose to 100° F on the afternoon succeeding the day of inoculation, and the patient complained of slight headache

In another case (N R, No 80) the temperature rose to 101 4° F on the afternoon following the day of inoculation Patient looked flushed complained of headache, and vomited undigested food once

In the case where the general reaction was most marked (M B, No 9) the test was applied at 7 P M on August 26th,

---

[4] Care was taken, where possible to test only apyrexial patients In very few cases was there any pyrexia due to complicating sepsis or other cause

The outlook for patients with a cirrhotic pancreas is usually fairly good, provided that a suitable diet is arranged as soon as possible after the discovery of the disease. I have not found that they are materially benefited by the starvation treatment and, as their digestive powers for all three classes of foodstuffs are deficient, the indications are rather to ensure sufficient nourishment than to worry unduly over the comparatively unimportant defect in carbohydrate metabolism

Strictly speaking the true hepatic type does not come under the heading of diabetes, for, although the urine reduces Fehling and Benedict s solution, &c., and gives an osazone with phenylhydrazine similar to that of dextrose, this is not due to the presence of a sugar but to an alphaketonic acid to which I have given the name "iso-glucuronic acid ' although it is more convenient to refer to it as pseudo-lævulose, since like lævulose, it is lævorotatory Pseudo-lævulose is met with in the urine of most advanced cases of diabetes along with dextrose, especially if the diet contains much protein, for it is from protein that it is probably derived, but it may also occur alone and lead to an incorrect diagnosis of diabetes To treat such cases on orthodox lines may do more harm than good The ordinary carbohydrate free diet only makes matters worse, and although starvation will clear the urine of reducing substances, the same result may be obtained, with much greater comfort to the patient, by eliminating, or strictly limiting, the protein in the diet and giving an abundance of vegetables, with dextrinised starches, in the form of oatmeal, potato &c , or pure dextrose Under this treatment the urine rapidly becomes normal, and after a few weeks the patient can gradually resume his ordinary food, provided that protein is taken sparingly So far as I can see at present the prognosis seems to be good for I have several patients who have remained sugar free and in excellent health for three or four years It seems probable that some of the success of the various carbohydrate " cures " for diabetes is to be explained by cases of this kind

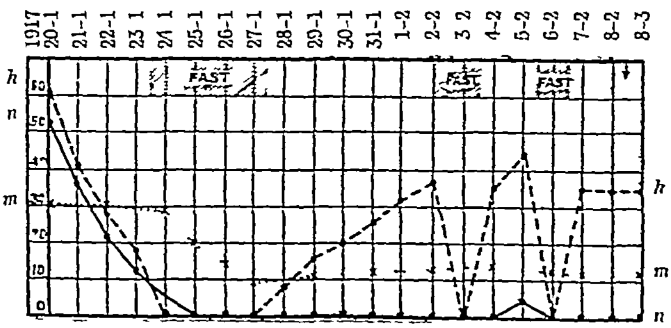
The Pancreo-Hepatic Type " Gouty " Glycosuria

In what I have termed the pancreo-hepatic type there may, or may not, be evidence of intestinal catarrh at the time they come under observation, but they always show signs of pancreatic insufficiency and more or less disturbance of the functions of the liver most likely the result of an infection from the intestine by way of the ducts or lymphatics The relative importance of the two conditions varies considerably and they merge into the pancreatic type in the one direction and into the hepatic on the other There is a corresponding difference in the probable course of the case

CHART 2



and the form of treatment most likely to be of benefit The prognosis is most hopeful when hepatic insufficiency is the more prominent feature such cases corresponding to what has been termed gouty glycosuria " Typical attacks of gout are very rarely seen however, but they are specially liable to what are termed ' gouty " complications in the shape of cardio-vascular or kidney disturbances, neuralgia, and neuritis, the last two being the most common and severe In reality these complications are dependent on the hyperglycæmia for they persist so long as there is an excess of sugar in the blood It is important to remember in this connexion that the disappearance of sugar from the urine does not necessarily imply a normal blood-sugar content, in fact it is the rule for the hyperglycæmia to continue after the urine is sugar free, so that if reliance is placed on analysis of the urine alone anti-diabetic treatment may apparently fail to control the symptoms

Pseudo-lævulose is generally present in these cases sometimes constituting more than half the total sugar Systematic examination of the urine usually shows, in addition striking variations in the excretion of uric acid and creatinine, which moves in curves with several days' or weeks' interval between the crest and trough of the waves Amino-acids are frequently present in considerable excess and an abnormal output of urobilin is a common feature The fæces may have the characters associated with catarrh of the upper intestine, but it is more common to find signs of chronic colitis

In some a short period of starvation is helpful, but I have obtained the best results by merely limiting the carbohydrate and protein for several days then giving one or two vegetable days followed occasionally by a porridge or potato day The subsequent diet is arranged according to the patient s tolerance for carbohydrate and protein, determined by regular blood and urine analyses In many instances an alternating diet arranged so as to control the pancreatic and hepatic insufficiency in turn is the most satisfactory

Typical ' gouty ' glycosuria is most common after middle life but even in younger people a predominance of the signs of hepatic insufficiency warrants a more cheerful outlook than when they are absent The tendency for the hyperglycæmia to persist after the disappearance of the glycosuria should be borne in mind if the treatment is to be really satisfactory, however

THE NEW DIETETIC TREATMENT OF DIABETES[1]

By P J CAMMIDGE, M D Lond

Treatment by Fasting

It is now many years since it was first suggested that patients suffering from severe diabetes should be starved until their urine became sugar free, but the suggestion was not generally adopted, as it was found that an alarming increase in the excretion of acetone bodies often occurred when the fasting had proceeded for a short time Acting on the experience gained with animals rendered more or less diabetic by partial removal of the pancreas, Allen gave a further trial to the method and found that, in the majority of cases, the acidosis which is apt to develop during the first few days of starvation subsides afterwards if the fasting is persevered with As a result he formulated a plan of treatment which may be summarised briefly as follows —

1 A preliminary fast is given until the urine is free from sugar

2 When it has been sugar free for 24 hours carbohydrate food is allowed in gradually increasing amounts, starting with green vegetables

3 Coincident with the addition of carbohydrate, or in place of it if the carbohydrate tolerance is very low, protein is introduced into the diet, in small but gradually increasing quantities, until glycosuria occurs, or a sufficient amount is being taken to cover the basal requirement of the patient

4 Fat is added to the diet in small quantities during the time the carbohydrate and protein tolerance are being tested, and is subsequently increased more rapidly until the fuel requirements of the body are met, provided that glycosuria does not develop and there is no increase in the acidosis

5 The appearance of sugar in the urine at any time is taken as an indication that a fast of sufficient length to cause a cessation of the glycosuria is necessary

6 A diet containing not more than half the carbohydrate being taken at the time sugar appears is then continued with for some weeks Later further additions are made very gradually

7 At intervals, depending on the severity of the case, the patient fasts, or greatly restricts the whole level of his diet, for 24 hours

8 Adult patients are not allowed to gain in weight, but a natural increase is allowed in children, although care is taken that the gain should not be in adipose tissue

9 Active daily exercise, carried to the point of healthy fatigue, is insisted on in all cases if possible

The details of the method necessarily vary somewhat according to the character of the case, as Allen himself has pointed out, although few of his disciples seem to be aware of the fact I do not propose to consider them here, however, but shall devote my attention mainly to the metabolic changes produced by the treatment and its effect on different types of glycosuria

Chronic Intestinal Catarrh

Everyone who has had more than a very limited experience of the condition to which the name diabetes mellitus is generally applied cannot avoid coming to the conclusion that it occurs in a variety of forms, with the one symptom of glycosuria in common, but differing widely in other respects This variation is even more marked when the blood, urine, and fæces of a number of cases are systematically investigated and compared During the last few years I have had the opportunity of making analyses of some 8 000 specimens from over 500 cases of diabetes, including 54 whom I have treated by Allen's method One of the most striking results of my investigations has been the frequency with which indications of a chronic catarrh of the upper part of the intestinal tract have been met with, such a condition being present in 71 per cent of my cases One can hardly assume that the relationship is accidental, or that the catarrh is a secondary phenomenon for the history very frequently shows that heartburn, flatulency, and other symptoms of indigestion preceded the discovery of sugar in the urine, often by several years while I have found that treatment directed to the intestinal condition frequently helps to control the glycosuria, whereas reappearance or accentuation of the catarrh may be followed by increase in the sugar excretion Cases of this description generally respond well to alimentary rest, but they are liable to relapse unless the intestinal condition is considered in the subsequent treatment.

The fasting treatment is based on the assumption that impairment of the functions of the pancreas is the cause of glycosuria in all cases and that the improvement in carbohydrate metabolism which results is due to the physiological rest given to the gland Although this may be true to some extent in cases with a chronic intestinal catarrh, it is probable that the starvation also has an effect on the intestinal condition, and that this helps to control the glycosuria. It may be a de-intoxicating process, as Guelpa supposed, but as Lombroso has recently shown that the intestine yields a glycolytic agent to the blood even more readily than the pancreas, it is possible that the physiological rest may influence the production of this substance, and so improve the utilisation of sugar At any rate, the analogy between the diabetes produced in animals by partial extirpation of the pancreas and in the human subject is probably not always as close as there has been a tendency to assume, since on the one hand we are dealing with a surgical mutilation of a non progressive character whereas on the other we have to treat a pathological state that tends to progress, and, even when checked, to recur

I could quote a number of cases to illustrate the relationship between the condition of the intestine and the progress of diabetes, but one will suffice —

A lady 26 years of age was sent to me at the beginning of August 1916 with the history that a month before she had begun to feel thirsty and was easily tired. As the symptoms increased she saw her doctor who found sugar in her urine and wrote to me for an appointment When she came I examined her blood and found 0 24 per cent of sugar while a specimen of urine she brought with her contained 6·2 per cent. giving a total excretion for the 24 hours of 124 gm Later on a test diet containing 3½ oz of bread and with a total carbohydrate content of 70 gm she passed 52 gm of sugar in the 24 hours The urine also contained 300 mg of acetone bodies but no oxybutyric acid 760 mg of ammonia nitrogen 450 mg of calcium 230 mg of magnesium and showed a normal creatinine and uric acid excretion and a normal nitrogen balance There was a very marked reaction for indican which worked out quantitatively at 128 mg The fæces were dark brown in colour rather soft in consistency, acid in reaction and gave a very marked reaction for biliverdin but contained no occult blood The trypsin index was slightly subnormal 200 units but there was no evidence of serious interference with fat digestion or absorption

This patient was not starved, as the glycosuria and hyperglycæmia quickly cleared when the carbohydrate intake was limited, and means were taken to combat the intestinal condition As the latter improved the diet was gradually increased, until ultimately 70 gm of carbohydrate were again being taken, but without there being any sugar in the urine The main interest of the case lies in the fact that the patient had consulted me two years previously for chronic indigestion, when there was no trace of glycosuria Her urine then contained a marked excess of indican, 188 mg , there was a high iodine coefficient (" pancreatic reaction) of 248 units, and an abnormal amylolytic ferment index of 67 units The fæces were at that time strongly acid in reaction, contained a considerable amount of unchanged bile pigment, and gave an abnormally high trypsin index of 5000 units Quantitative analysis showed a relative excess of combined fatty acids and a very low proportion of neutral fat There was evidently, then, very considerable catarrh of the upper part of the intestinal tract, with secondary catarrhal pancreatitis, and in a letter to the patient's doctor I pointed out the possibility of diabetes supervening if the condition progressed, as, unfortunately, it appears to have done (Chart 1)

Classification

It is comparatively uncommon, in my experience, to find evidence in the urine and fæces of advanced cirrhosis of the pancreas in diabetics As a rule a cirrhotic or malignant, pancreas is associated with only traces of sugar 5 gm , or less, in the 24 hours and it is rare also to meet with acetone or signs of acidosis even when as occurs exceptionally, the sugar excretion rises to 50 or 100 gm a day

Signs of some interference with the digestive functions of the pancreas were found however, in the majority of my cases (72 per cent) and in most of them (67 per cent.) there were indications that the functions of the liver were also being imperfectly carried out In some 27 per cent. the hepatic disturbance was apparently more pronounced than the pancreatic

It is consequently convenient to recognise three types (1) the pancreatic (2) the hepatic, and (3) the pancreo-hepatic—a classification I find of considerable help in prognosis and treatment

---

[1] A paper read before the Harveian Society on April 19th 1917

The outlook for patients with a cirrhotic pancreas is usually fairly good provided that a suitable diet is arranged as soon as possible after the discovery of the disease. I have not found that they are materially benefited by the starvation treatment, and, as their digestive powers for all three classes of foodstuffs are deficient, the indications are rather to ensure sufficient nourishment than to worry unduly over the comparatively unimportant defect in carbohydrate metabolism.

Strictly speaking, the true hepatic type does not come under the heading of diabetes, for, although the urine reduces Fehling and Benedict's solution, &c. and gives an osazone with phenylhydrazine similar to that of dextrose, this is not due to the presence of a sugar but to an alphaketonic acid to which I have given the name "iso-glucuronic acid," although it is more convenient to refer to it as pseudo-lævulose, since, like lævulose, it is lævorotatory. Pseudo-lævulose is met with in the urine of most advanced cases of diabetes, along with dextrose, especially if the diet contains much protein, for it is from protein that it is probably derived, but it may also occur alone and lead to an incorrect diagnosis of diabetes. To treat such cases on orthodox lines may do more harm than good. The ordinary carbohydrate free diet only makes matters worse, and, although starvation will clear the urine of reducing substances, the same result may be obtained, with much greater comfort to the patient, by eliminating, or strictly limiting, the protein in the diet and giving an abundance of vegetables with dextrinised starches, in the form of oatmeal, potato, &c., or pure dextrose. Under this treatment the urine rapidly becomes normal and after a few weeks the patient can gradually resume his ordinary food, provided that protein is taken sparingly. So far as I can see at present the prognosis seems to be good, for I have several patients who have remained sugar free and in excellent health for three or four years. It seems probable that some of the success of the various carbohydrate "cures" for diabetes is to be explained by cases of this kind.

CHART 1.

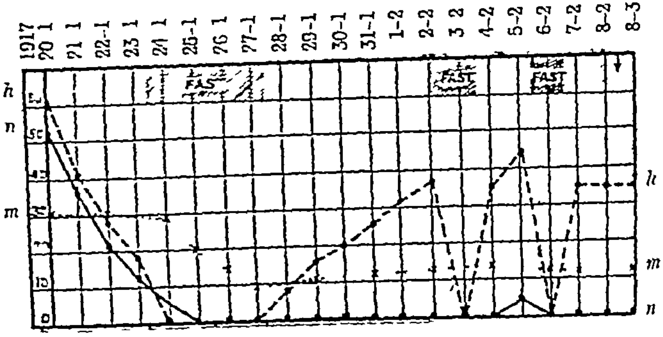
The Pancreo-Hepatic Type: "Gouty" Glycosuria.

In what I have termed the pancreo-hepatic type there may, or may not, be evidence of intestinal catarrh at the time they come under observation, but they always show signs of pancreatic insufficiency and more or less disturbance of the functions of the liver, most likely the result of an infection from the intestine by way of the ducts or lymphatics. The relative importance of the two conditions varies considerably and they merge into the pancreatic type in the one direction and into the hepatic on the other. There is a corresponding difference in the probable course of the case and the form of treatment most likely to be of benefit. The prognosis is most hopeful when hepatic insufficiency is the more prominent feature, such cases corresponding to what has been termed "gouty glycosuria." Typical attacks of gout are very rarely seen, however, but they are specially liable to what are termed "gouty" complications in the shape of cardio-vascular or kidney disturbances, neuralgia and neuritis, the last two being the most common and severe. In reality these complications are dependent on the hyperglycæmia, for they persist so long as there is an excess of sugar in the blood. It is important to remember in this connexion that the disappearance of sugar from the urine does not necessarily imply a normal blood-sugar content; in fact, it is the rule for the hyperglycæmia to continue after the urine is sugar free, so that if reliance is placed on analysis of the urine alone anti-diabetic treatment may apparently fail to control the symptoms.

CHART 2.

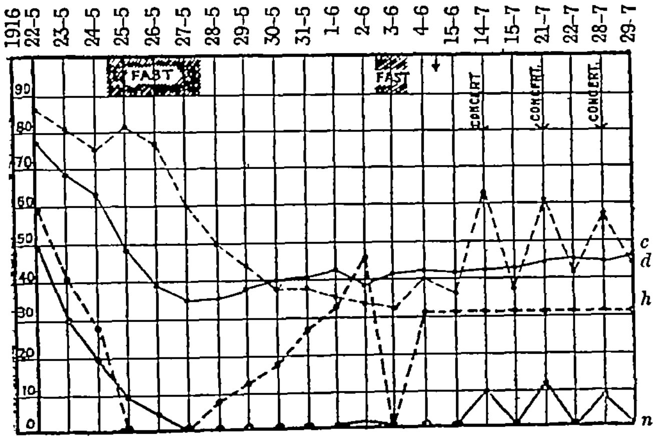


Pseudo-lævulose is generally present in these cases, sometimes constituting more than half the total sugar. Systematic examination of the urine usually shows, in addition, striking variations in the excretion of uric acid and creatinine, which may rise and fall with several days' or weeks' interval between the crest and trough of the waves. Amino-acids are frequently present in considerable excess, and an abnormal amount of [illegible] is a common feature. The fæces may have the characters associated with catarrh of the upper intestine, but it is more common to find signs of chronic colitis.

In some a short period of starvation [illegible] helpful, but I have obtained the best results by [illegible] limiting the carbohydrate and protein for several days, then giving [illegible] [illegible]

I have recently had under my care a case of this type in a young woman of 28 who had been twice treated by alimentary rest by different physicians with apparently satisfactory results at the time, but on each occasion sugar reappeared in her urine within a short period of her return home I found that as on previous trials, the urine became sugar free after two days starvation but examination of her blood showed that it contained 0·2 per cent of sugar as compared with 0 29 per cent before she was deprived of food and 0 3 per cent when she first came under observation It was not until she had starved for another two days that it dropped to 0·09 per cent. The patient went home with a new diet scheme and has remained sugar free for a month, while her blood sugar has not risen higher than 0 13 per cent (Chart 2)

CHART 3



Experiences of this sort bring home to one the necessity for controlling examination of the urine for sugar by analysis of the blood, and emphasise the fact that the aim of our treatment of diabetes should be to prevent hyperglycæmia, not merely to eliminate sugar from the urine So long as blood sugar estimations were difficult to carry out there was a valid excuse for our relying entirely on urinary analysis, but the modern micro chemical methods[2] require so little material and are so readily performed that we should no longer be "content with the shadow, but grasp at the substance "

The Nervous Factor

There can be no doubt that there is a nervous factor in many cases of diabetes although it is rarely possible to prove it I am inclined to think that the relation between the calcium and magnesium output in the urine may afford some indication, for I have found that the latter is usually higher than the former in nervous people, and on several occasions I have seen a sudden rise in the magnesium excretion, with little or no change in the calcium as the result of nervous disturbances or injury

Cases in which a nervous element is probably present answer well to alimentary rest, but always do best when treated away from home and their ordinary surroundings, owing probably to the mental effect of the change in environment I urge these patients to take as much fresh green vegetable as possible because of the inorganic salts they contain, and I find that minute doses of magnesium sulphate three or four times a day tend to steady their nervous system and consequently control the glycosuria Purgative doses should be carefully guarded against, however

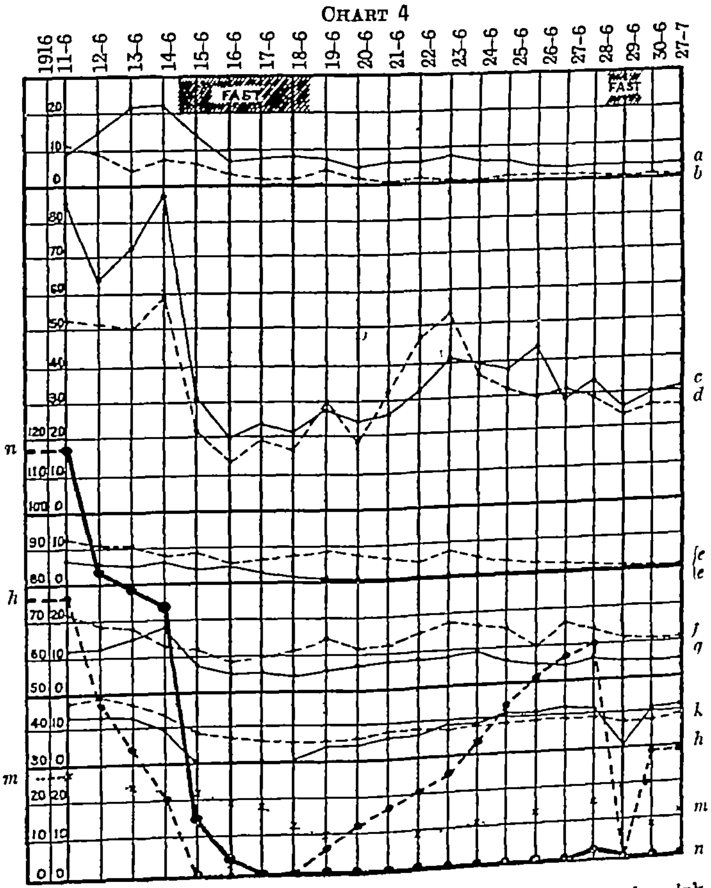
One of the most striking examples of the influence of nervous excitement on sugar excretion I have met with was in a musician who came under my care last year Originally he excreted about 50 gm a day but became sugar-free after three days and four nights of starvation the blood sugar coming down to normal next day On the diet that was eventually worked out for him he remained sugar-free for over a month Three days after he returned to work he passed 10 gm of sugar although no change had been made in the diet and the next day's specimen was sugar-free The same thing happened the following week and I then found that on each occasion he had taken part in a concert and had been particularly affected by the music. So as an experiment I asked him to attend another of the same series of concerts, with the result that he again passed sugar in his urine He has since confined his activities to less exciting work and has had no return of the glycosuria. (Chart 3)

Questions in Regard to Advising Fasting

From what I have said it will be gathered that I do not look upon Allen's fasting treatment as the best for all forms of glycosuria, although I consider that it marks a great advance in the available methods and gives results which can be obtained by no other means in many instances It should be used with judgment however, and one should always bear in mind that the keynote of the treatment is under nutrition. A practical question that sometimes arises therefore, is whether a controlled, and may be a mild glycosuria, with an adequate diet and reasonable enjoyment of life, is not preferable to the theoretical ideal of a permanently sugar free urine, which can only be obtained by a diet that will not satisfy the pangs of hunger and requires constant close supervision? The answer will depend on circumstances and the temperament of the patient These should be considered carefully before advising the treatment, especially as, once it is begun, it must be continued, for as I pointed out in an article last year,[3] the return to an ordinary carbohydrate free diet almost inevitably brings about a rapid increase in the acidosis, with excessive tissue waste and death from coma.

That such should be the case is not difficult to explain Daily analysis of the urine during the fasting period shows that coincident with the fall in the sugar excretion there is a drop in the whole level of metabolism, the total nitrogen sinking until it stands at a steady level of 4 gm or 5 gm a day At first there may be a rise in the output of uric acid and creatinine, but as the fasting proceeds they also sink and the same is true of the amino acids A most striking change generally occurs in the acidosis At first this, as shown by the total acidity, ammonia nitrogen calcium, and

CHART 4



---

[2] THE LANCET April 21st, 1917, p 613

[3] Practitioner 1916

magnesium, may rapidly increase, and there is a corresponding rise in the excretion of acetone bodies Sometimes the oxybutyric acid output is also increased temporarily but often it falls from the first day, and is replaced by a larger excretion of acetone and aceto acetic acid Ultimately these also begin to clear, although some acetone may be excreted for a considerable time Finally the ammonia, calcium, and magnesium, with the total acidity, reach normal levels, and the urine may afterwards become alkaline as vegetables are taken After feeding is commenced, and particularly when protein foods are introduced into the diet, the total nitrogen rises again, but if the dieting is properly carried out the patient remains in nitrogenous equilibrium, and there is no increase in the acidosis (Chart 4)

Supposing now that a patient in this condition is suddenly transferred to a "carbohydrate free" diet, the immediate effect of the largely augmented protein intake is to stimulate metabolism some 50 per cent or more over what it would have been had the same caloric value been given in the form of carbohydrate, with the result that there is rapid tissue waste, with a greatly increased excretion of amino-acids, uric acid, creatin, and creatinine, a rise in the formation of acid bodies, and consequently increasing depletion of the alkaline reserves of the body, which are no longer being replenished by the bases contained in the vegetables that previously constituted so large a part of the diet More fat and less carbohydrate are also being taken, so that the products of the imperfect combustion of fat are increased and added to the total acid bodies, still further depleting the alkaline reserves in the organism Choked by the accumulated "clinker" of a diet it is incapable of metabolising, and worn out by the attempt to utilise its own tissues as a source of energy, the body soon becomes unable to carry on its work and the patient dies of diabetic coma

Acidosis

Formerly the most common cause of death in diabetes, coma should now be one of the rarest, for in starvation, followed by a largely vegetable diet, we have a powerful weapon for preventing and controlling the acidosis from which it arises Essentially, acidosis results from the imperfect oxidation of fat and this in its turn is dependent upon the faulty combustion of carbohydrate by the body, for fat seems to be a less readily oxidised foodstuff than sugar and needs the fire of burning sugar to bring about its complete combustion It has been calculated that one part of dextrose to three parts of higher fatty acids is required for the purpose If less than this proportion is available the fat "smokes," as it were the smoke being represented in the body by abnormal acid products Since the maximum rate at which dextrose can be oxidised by the diabetic is always lower than in health, the diabetic is not capable of completely utilising as much fat as a normal individual, so that acidosis is more prone to develop

In order to check a diabetic acidosis it is necessary to restore the proper relation of fatty acid to dextrose oxidation, which may be done by diminishing the fat in the body and increasing the power to utilise carbohydrate Fasting will obviously ensure the former, and it is well known that it also tends to increase carbohydrate tolerance, so that abstinence from food is the most rapid method of restoring the required balance The immediate result of starvation will depend however, on the amount of fat stored in the tissues and therefore on the nature of the previous diet If a diet rich in fat has been taken and there is a considerable deposit of adipose tissue the sugar available may be quite inadequate to ensure anything like complete combustion, and there will consequently be a rapid rise in the acidosis until the fat has been used up and a more normal relationship has been reached but even then the acidosis may continue to increase, for proteins contain fatty acid radicals yielding acid bodies when they are imperfectly oxidised and some diabetics have lost the power of utilising more than a small proportion of the dextrose contained in the protein molecule which normally serves for their combustion By persisting with the starvation the ability of the organism to utilise carbohydrate usually becomes so far restored that enough is available to control the formation of abnormal acid end products from both sources

Some Practical Conclusions

From a consideration of these facts it is obvious that all cases of diabetes cannot be expected to react to starvation in the same way the determining factors being the amount of stored fat the power to utilise the carbohydrate deposited in the form of glycogen, and the extent to which sugar of protein origin can be made use of Hence three practical conclusions may be drawn —

1 There is more danger of serious acidosis developing during starvation in fat than in thin diabetics

2 When acidosis is present the patient should be prepared for the starvation treatment by being put on a fat poor diet for several days before abstinence from food is commenced

3 An initial increase in the acidosis is to be expected, but should not stop the treatment unless it assumes threatening proportions, as it will most likely subside if the fasting is persisted with

Occasionally nausea, marked prostration, increasing drowsiness, and deep breathing, in conjunction with the characteristic changes in the composition of the blood, alveolar air, and urine, indicate a severe and progressive acidosis The fast should then be terminated for the time being and the treatment directed to the acidosis A restricted diet, consisting chiefly of green vegetables, with alkaline therapy, for a few days will generally suffice to control the condition, and a further fast will then usually result in improved carbohydrate tolerance and a sugar-free urine without increasing the acidosis

During the fasting periods weak patients should be kept in bed, but the more vigorous should be encouraged to take as much exercise as is practicable, since the duration of the fast is shortened thereby After feeding is commenced regular exercise should be continued, and even weak patients should have massage or regulated exercises Short periods of vigorous exercise are to be preferred to long monotonous walks, and are particularly advantageous immediately following a meal containing carbohydrate, but care should be taken to avoid excessive fatigue Exercise is of especial benefit for children, as it promotes the building of active tissue at the expense of fat and favourably influences growth Mental occupation is most desirable, and patients should be encouraged to continue their ordinary work as far as possible

The Protein Intake

Long before the appearance of Allen's work I had come to the conclusion that quantitative regulation of the diet is necessary in all cases of glycosuria and that control of the protein intake is quite as important as adjustment of the carbohydrate for the exhaustive chemical analyses of the excreta carried out in most of my cases showed that merely eliminating sugar from the urine does not suffice to control the disease if the patient is not in nitrogenous equilibrium, and that the only way to maintain this condition is to teach him to take his diet quantitatively A number of papers published between 1912 and 1915 embodied these conclusions, and it is therefore gratifying to find that they are important features of Allen's plan, although I regret to see that in the attempt to simplify the treatment a rule-of-thumb method for establishing a nitrogenous balance is generally advocated instead of the more laborious, but certain, determination by direct chemical analysis

Systematic examination of the urine shows that when the protein in the diet of a diabetic is gradually increased beyond a certain point varying with each case, evidences of a disturbance of nitrogenous metabolism appear before sugar can be demonstrated in the urine and that if these are at once recognised and the protein cut down glycosuria can be prevented Merely to rely upon the appearance of sugar in the urine is therefore far from being an ideal method of regulating the treatment My experience with several patients who have come under my care after treatment with alimentary rest by others has confirmed my distrust of this "hit or miss" process of determining the protein tolerance

As an example I may quote the case of a young man who consulted me in the beginning of January He had been treated in the previous November by a physician who has copied Joslin's method of applying the fasting treatment and stated that after a 24 hours fast his urine had been found to be free from sugar His final diet on which he had remained sugar free according to Fehling's test contained 60 gm of carbohydrate and 16 gm of protein with as much fat as he cared to take He complained that although he had strictly adhered to the quantities allowed he was steadily losing strength was exceedingly miserable, and suffered from frequent attacks of cramp

Temporarily continuing the same diet I found that a 24 hours specimen of his urine gave no reaction for sugar with Fehling and showed only a slight turbidity with Benedict's test while quantitative analysis gave just over 1 gm of sugar for the day Determination of the sugar-content of the blood showed 0·19 per cent two hours after the morning meal so there was evidently some hyperglycæmia. Further investigation of the urine revealed other important changes The total nitrogen exceeded the intake by more than 2 gm there was a very high uric acid output, the creatinine excretion was nearly double the normal the amino-acid nitrogen amounted to 200 mg a day the true ammonia was just over 1 gm and there were 140 mg of oxybutyric acid and 893 mg of acetone bodies besides an excess of calcium and magnesium After a few days on a fat-poor vegetable diet and one day of starvation, the blood sugar fell to 0·06 per cent the total nitrogen of the urine dropped to 5 gm., the oxybutyric acid disappeared and the uric acid creatinine ammonia nitrogen calcium and magnesium excretions fell to normal, while only traces of amino-acids could be found His diet was then gradually worked up again guided by the results of daily complete analyses of the urine and blood sugar estimations when it was found that although his carbohydrate tolerance still stood at about 60 gm. he could only be kept in nitrogenous equilibrium and his blood sugar maintained at normal figures if the nitrogen intake did not exceed about 10 gm a day With a diet containing these amounts and a specified quantity of fat he became more cheerful ceased to lose weight, and no longer suffers from cramp

I need not discuss in detail the adjustment of the carbohydrate content of the diet to the patient's tolerance, as provided he is kept in nitrogenous equilibrium, it is a comparatively simple matter, although I should again like to emphasise the importance of controlling the urinary analysis by examination of the blood In passing I may also remind you that the carbohydrate and protein in the diet of a child should not be increased at the same rate as in an adult, but proportional to the weight, 1 gm of carbohydrate for a child of 15 kg, for instance, being about equal to 4 gm for an adult

The Fat Intake

The regulation of the fat intake in diabetes requires much more care than is frequently given to it Hitherto fat has generally been regarded as a "make weight" by which the caloric value of the diet can be adjusted to the theoretical requirement worked out from the patient's weight, but modern research suggests that this idea, like that formerly held with regard to proteins must be abandoned, and that careful control of the fat-supply is no less important than a correct adjustment of the protein and carbohydrate intake

It is still a debatable point whether sugar can be derived from fat, but apart from this the recent experimental work of Allen on dogs has shown that restriction of the carbohydrate and protein in the diet alone only serves to suppress the symptoms temporarily and that unless the total metabolic load on the weakened assimilative functions is lightened by keeping the fat also within strict limits, downward progress, similar to that often seen in the human subject, occurs The observations of Bloor on the blood have likewise demonstrated that defective fat metabolism is much more common in diabetes than has been supposed, for he found that abnormal lipoid values occur very frequently, apart from obvious lipæmia Bloor showed that these lipoids originate from the fat of the food, an increase leading to an accumulation of fat and its metabolites in the blood until a point is reached when they can be no longer held in solution by the plasma, while fasting and a reduced fat intake have the opposite effect and bring about more efficient metabolism There appears to be no definite relation between the lipoid content of the blood and the excretion of acetone bodies in the urine, however Regular determinations of the lipoids in the blood would no doubt afford the best guide to a correct adjustment of the fat content of the diet and prevent overloading of the faulty mechanism, but the process is too long and complicated for routine clinical work at present and one has to fall back upon such rough tests as the appearance of the blood and changes in weight

I have already indicated the importance of not commencing the fast in severe cases with acidosis until the patient has been prepared by a few days on a fat poor diet, but it is equally important that fat should not be added to the diet subsequently until a considerable tolerance for carbohydrate and protein has been established Eggs are therefore often not the best form of protein to start with, as is usually advised A creamy blood an increase in the ketonuria, or the appearance of sugar after more fat has been introduced into the diet should be controlled by reducing the fat intake, otherwise it is best so to regulate the diet that a progressive loss of weight is prevented while a gain, or rather an increase in adipose tissue, is avoided

Periodical Curtailment of Diet

Even when the total caloric value of the diet and the body mass have been reduced to correspond to the defective assimilative capacity of the patient there is a risk that his metabolic powers may still be over taxed if they are constantly worked at the same level It is therefore advisable that the diet should be materially curtailed at regular intervals The extent of the reduction and the frequency with which it is required will depend upon the severity of the case and the response to the preliminary treatment so that no hard and fast rule can be laid down, but generally an all round reduction by one half for one day each week is required. In some cases this means that the patient must fast, in others that he is limited to low value green vegetables, maybe with two or three eggs, while in others again a fair amount of carbohydrate food can be taken provided that the fat and protein intake are kept low When carbohydrate tolerance is very defective it may be advisable to prescribe one or two vegetable days in addition.

As the patient improves his allowance of carbohydrate is gradually increased, and the stringency of his fast, or semi fast, days reduced, but he must advance a step at a time with sufficient interval between each to test thoroughly hi powers of dealing with the larger ration The protei allowance in any case should aim at the standard o Chittenden rather than that of Voit, and no addition shoul be made, under any circumstances, until the patient ha been in nitrogenous equilibrium for several weeks and al traces of acetone bodies have disappeared from the urine even then it should be increased very cautiously guided by the relation between the nitrogen content of the diet and the output in the urine In this connexion I may point out tha many so-called diabetic foods and breads, if not fraudulen as regards their carbohydrate content, consist chiefly o protein, which must be allowed for when they are used A ordinary bread is rarely well tolerated by diabetics, som substitute of this description is often most useful, but should never be given unless its carbohydrate, protein, an fat content are known and its composition is reliable

Acid-Base Equilibrium

I should have liked to consider in detail a subject which I have recently devoted considerable attentio namely, the influence of the inorganic salts of the die and particularly the alkaline bases, on metabolism diabetes, but a brief reference must suffice at presen Incidentally I have referred to one aspect of the matt when speaking of nervous disturbances, and it is needle to remind you of the importance of alkalies in treatu acidosis, but there are other problems involved th these Experiment has shown that the mechanism regul ing the level of the blood sugar is peculiarly sensitive disturbances in the acid base equilibrium of the body, ac production leading to hyperglycæmia, while alkalosis exe an opposite influence Since meats and cereals are general acid producing foods, while vegetables and fru usually yield an excess of bases, a diet rich in protein w tend to raise the sugar content of the blood, whereas vegetable diet will lower it May this not be one of t reasons why the largely vegetable diet usually given aft the fast in the alimentary rest treatment is associated wi an increase in carbohydrate tolerance, and a partial explan tion of the deleterious effect of more protein than is need for making good the actual wear and tear of the body [7]

Applying these ideas concerning the influence of the aci base equilibrium of the body on carbohydrate metabolism treatment, Murlin and Kramer and more recently Underhi have reported considerable improvement in cases of glyc uria subjected to careful alkaline therapy Underh employed large doses of sodium bicarbonate while Murl and Kramer used normal sodium carbonate, given int duodenally in 1 per cent solution That alkalies increa sugar tolerance is an old idea which has been under a clo for some years but old clinical beliefs often contain a ge of truth, and it seems that further research on these li may reveal methods of controlling glycosuria other th mere limitation of the diet

At present our only reliable means of combating the dise is management of the diet, but in order to obtain the b results and actually halt the diabetic process it is necess that it should be carried out with knowledge and as n discrimination as the selection and prescription of a dr Time and care devoted to the chemical aspect of each c render the task easier and would prevent the empir employment of one routine method so saving many patie from unnecessary hardships and inconveniences It is enough to consider only the glycosuria, or even the end products of metabolism in the urine, the information to be obtained from analysis of the blood and fæces should also be taken into account, and I venture to think that the time is coming and will come shortly, when a physician who attempts to treat a case of diabetes guided only by examination of the urine for sugar will be held as guilty of negligence as the present-day surgeon would be who failed to employ radiography when treating an injury of the bones or joints

Nottingham place W

THE LOCAL TREATMENT OF MENINGOCOCCUS CARRIERS WITH ANTISEPTICS

(A REPORT TO THE MEDICAL RESEARCH COMMITTEE)

BY P FILDES, M B , B C CAMB
ASSISTANT BACTERIOLOGIST TO THE LONDON HOSPITAL HONORARY STAFF SURGEON R.N V R
AND
P B WALLIS, B A CAMB M R C S , L R C P LOND ,
SURGEON R.N
(*From the Laboratory, R N Hospital, Haslar*)

OWING to the measures adopted in the Navy to limit the spread of cerebro spinal fever a large number of carriers were detected in the Portsmouth depôt and isolated in a special camp It then became necessary to attempt to sterilise the throats of these men, and, although from analogy with other diseases the local application of antiseptics appeared likely to be unprofitable it was thought desirable to give these a trial If the antiseptic did not destroy the cocci in the throat, it was possible that it might prevent the cross-infection from one man to another Further, the use of inhaling rooms in the Army had been said to give encouraging results

In an experimental treatment of this sort there were three important matters to be considered (1) The antiseptic to be used , (2) the method of application , and (3) the index of cure

1 *The Antiseptics Used*

The antiseptics most thoroughly tested were chloramine T and acriflavine Dakin's new dichloramine compounds came to hand too late in the season to make a satisfactory test Other antiseptics were boracic acid, carbolic acid, magnesium hypochlorite, formalin, potassium permanganate, guaiacol, and several others In addition to these, we administered to a few men a placebo in the form of tablets of formalin

2 *The Method of Application*

Chloramine T was applied in two different ways —

(*a*) In an inhaling chamber, the drug being dispersed as a fine cloud by a high pressure steam jet This apparatus differed in design from that proposed by Colonel M H Gordon for the Army, but no doubt gave similar results A 5 per cent solution of chloramine T was used in the reservoir of the nebuliser , this strength was found to give as powerful an atmosphere of chlorine as was pleasant The room accommodated about 10 men and these remained therein for about 15 minutes per diem They were instructed to breathe strongly through the nose during this time but there was no way to ensure that these orders were carried out and in many cases they probably were not

(*b*) In a nasopharyngeal spray This was a glass hand spray made by one of us the nozzle of which was readily slipped through the mouth into the nasopharynx Two or three pumps were given with the bellows and the chloramine T (2 per cent) thus came copiously into contact with the whole nasopharynx and often dripped from the anterior nares This treatment was applied once a day

Acriflavine (kindly supplied to us by the Medical Research Committee) in a strength of 1 in 500 in salt solution was applied daily with our nasopharyngeal spray

The other antiseptics mentioned were used in the earlier stages of the investigation They were all applied with Parke Davis and Co s Glaseptic' nasal spray until the drug could be felt in the nasopharynx The strength of boracic acid was one drachm to the pint of carbolic 1 in 200 of formalin 1 in 200, and of potassium permanganate 1 in 1000.

3 *The Index of Cure*

The apparent value of these antiseptic treatments depends very largely upon what end it is proposed to achieve and the exact manner in which the process is carried out In general the technique is to apply the treatment until swabs taken from the nasopharynx fail to reveal the meningococcus The man is then looked upon as cured There are, however, a number of fallacies which must be avoided

(*a*) The treatment must not be carried on continuously during the whole period of quarantine for two reasons First, the treatment if applied on the day that the swab is taken will directly vitiate the result We have therefore always allowed 24 hours to elapse after treatment before the swab is taken Secondly the treatment if applied continually will readily diminish the number of meningococci or reduce their vitality so that they will not grow in culture, but when treatment is stopped they will frequently reappear again It is therefore essential not to apply treatment continually, but to give the man a chance of relapsing before he is said to be cured In practice the routine has been as follows — 1 Upon receipt a positive carrier is treated once a day until his next swab is due—that is to say, until six days have elapsed since the first swab In practice this is usually one or two days' treatment 2 Treatment is stopped 24 hours before the swab is taken 3 It is continued after the swab is taken until the report is received 4 If this is negative treatment is stopped, and if the man remains negative on weekly test, no further treatment is given 5 If the report is positive, treatment is continued until the next swab is due More recently, in order to give the "positives" a greater degree of treatment, we have swabbed them while positive every 14 days instead of every week On a negative swab being obtained, however, we reverted to the weekly tests

(*b*) A certain period of time must be allowed to elapse after a negative swab is obtained before a man is said to be cured, in order that the permanency of the cure may be established It is customary for a certain number of negative swabs at fixed intervals of time to be required before a man in the services is allowed out of quarantine The precise number of swabs has never, to our knowledge, been accurately worked out In the Army it was two, while the Navy at one time required six weekly negative swabs During the past season this number was reduced to four All our carriers, therefore, have been retained under observation until at least four negative swabs have been obtained, and we are thus able to give more accurate information as to the permanence of cure in these cases

The following figures show the number of relapses which occurred after various numbers of "negatives" had been obtained 375 carriers (pure 'Gordon" types) were subjected to the "4-negative" standard Of these—

137 relapsed (185 times) after 2 negatives" = 36 per cent
63 (74 times) 3 = 16

A small number of men were examined by mistake or for various reasons for more than the necessary 4 "negatives" Of these—

13 carriers relapsed after	4 negative swabs
5	5
4	6
2	7

The number of carriers who were examined after four "negatives" is so small that no statistical capital can be made out of these latter figures Nevertheless it is certainly remarkable that so many relapses were observed in so few cases From the foregoing figures it is clear that if two negative swabs are taken as the index of cure no less than 36 per cent of the men will, in fact, not be cured, and will be returned to the community in the same condition as they were before they were isolated It is also clear that under these conditions of "cure" a form of treatment may readily be supposed to have a value which is quite fictitious

The number of negative swabs which constitutes a cure is a practical question which has to be decided with due regard both to inconvenience to the Service and to safeguarding the Service It appears to us that it would be irrational to undertake a very extensive system of control, as in the Navy and then to stultify that system by prematurely discharging one-third of the proved carriers on two negative tests Clearly the proved carrier is the man on whom attention should be most concentrated if extensive administrative measures are taken against this disease at all and thus it would appear that the naval routine of four "negatives' is better than two "negatives The number of men involved when the carriers are only derived from contacts is so small relatively to the whole Service that four 'negatives" should not entail undue inconvenience In all our cases, therefore, the index of cure has been four consecutive negative swabs taken at weekly intervals During the whole of this time no treatment has been applied in order that every opportunity for early relapse might be present

The Results of Treatment

Owing to the relatively small number of carriers and to the fact that at first the treatment was often changed, the estimation of the value of these different methods is difficult On examining the figures, however, it is soon found that there is another factor which enormously increases the difficulty—namely, that one third of the men become cured immediately upon entry into the isolation camp *whatever the treatment applied to them may be* Thus of 375 carriers of pure "Gordon" types, 124 registered their four consecutive negative tests immediately upon entry into the isolation camp The treatment applied to these men was practically nil, since by the time the "doubtful" colonies had been proved to be positive, and the man had been removed to the isolation camp, the greater part of the week had passed and only one, or at the most two, days' treatment remained before it had to be stopped preparatory to the next swab When it is remembered that this treatment consisted of formalin tablets and boracic nasal sprays, as well as chloramine-T and acriflavine nasopharyngeal sprays, it appears justifiable to us to regard the effect of treatment as nil, and to assume that these men cleared up spontaneously Since, then, one third of the men are cured spontaneously, a drug must be very decisive in results before its curative action becomes very obvious

The effect of the antiseptics has been estimated in two ways (1) by calculating the ratio of cures to the number of men treated by each antiseptic, and (2) by counting the number of men who obtained 4, 3, 2, 1 or no "negatives" *immediately* upon starting upon a particular treatment

TABLE I.—*Showing the Cures Effected by Various Treatments*
TABLE II —*Showing the "Immediate Negatives" obtained by Various Treatments* *

* In Table II the cure is credited to that treatment under which the man was last

Table I shows that about 50 per cent of the men treated by any method were cured Any variation in the percentage is not greater than might be produced by chance and has no significance

Table II shows that with each form of treatment 40–50 per cent of the men are cured immediately, with boracic acid alone is the figure much higher, but here the factor of error due to small numbers comes in acutely This percentage (40–50) corresponds roughly to that given by all treatments together (33) which, as has been explained, may be assumed to be no treatment The difference between the 33 per cent of no treatment and the 40–50 per cent of treatment is due, not to the efficacy of treatment but to the fact that the two figures are calculated from two different series of men The 33 per cent relates to carriers of meningococci which agglutinate with monovalent sera while the 40–50 per cent refers to a series which includes in addition a number of carriers of cocci which agglutinate feebly or not at all with monovalent sera These latter often fail to agglutinate, and therefore these carriers are more easily "cured"

It is clear that the therapeutic effect of none of these antiseptics is sufficiently great to class one as better than another

On examining the figures of those men who remained positive after treatment, it is again observed that the results are fairly similar, about one third of the men failed to obtain a negative immediately after treatment Acriflavine and boracic are exceptions to this rule, the former showed only 4 positive in 101 after treatment, and the latter 1 positive out of 31 In the case of acriflavine these positives have passed into the group of "1 immediate negative," and there is some evidence that acriflavine actually does produce a transient inhibition of the bacteria

Conclusion

Looking at the results as a whole, we conclude that one third of the men recover spontaneously, and that none of the methods of treatment tested has any conspicuous merit, nor has one any obvious advantage over another This result is what might be expected from analogy with work on diphtheria carriers

We are much indebted to Dr John Brownlee, statistician to the Medical Research Committee, for opinions upon figures submitted to him

ON THE CLOSURE OF WAR WOUNDS IN HOME HOSPITALS

BY JAMES PHILLIPS, F R C S EDIN,
MAJOR, R.A M C (T C) OFFICER IN CHARGE, SURGICAL DIVISION BRADFORD WAR HOSPITAL.

As the result of experience gained during the last two and a half years it has been found possible to render wounds, the discharges from which have been teeming with pus organisms, surgically clean, so that in a period varying from a very few days to at most a week or two, an infected wound can be stitched up with every prospect of something approaching primary union taking place

The two surgeons whose names are chiefly associated with these results are in this country, Rutherford Morison and, in France, Carrel. Through the courtesy of Sir Berkeley Moynihan I was privileged in October, 1916, to see Mr Rutherford Morison demonstrate his method of treating war wounds with "B I P P," and also to hear Dr Sharman, of Pittsburg, who had spent some months in France seeing war surgery, relate his experiences at Carrel's hospital More recently I heard Colonel C J Bond, of Leicester, describe the Carrel-Dakin treatment, and not less useful have been several discussions on the subject with Colonel Moynihan himself

Between November, 1916, and the end of June, 1917, I have performed well over 300 operations for the closure of war wounds at the Bradford War Hospital and have gradually evolved a technique (which will probably be further modified as my experience grows, but) which already gives me results which I regard as very satisfactory and which I propose to describe in this article This I shall do at some length, since I consider that the highest percentage of good results can only be obtained by following out the method in detail

The Carrel, B I P P and Bradford Methods

The Carrel method —The Carrel treatment consists (1) in the sterilising of the wounds, and (2) in the suture of the surgically clean wound When a case is seen soon after the wound has been inflicted an anæsthetic is given, the skin around the wound is thoroughly cleaned and the wound is freely opened up foreign bodies lacerated muscles, damaged skin edges and loose bone fragments are removed all bleeding is stopped and special tubes are inserted, through which is instilled into the wound every two hours a solution containing 4 5 per cent of active chlorine—the object being to keep an efficient antiseptic constantly in contact with the whole of the wound surface. The discharge is microscopically examined every day or two, and in from 5 to 11 days the wound is usually sterile enough (1 organism to each 4 microscope fields) to enable it to be completely stitched up and for primary union to result Colonel Moynihan tells us that notices are hung up in Carrel's wards to the effect that every wounded man whose wound suppurates has a right to demand an explanation from his surgeon !

Now the problem of wound closure in the British war hospital is not so simple as this Cases come over from France in hundreds labelled "Carrel Dakin treatment"—with one convoy over 40 such cases came to Bradford—but they are almost without exception suppurating generally profusely, commonly the tubes have been removed, and if they are still in the instillation of Dakin's fluid has been intermitted. The process of wound cleansing has to be started all over again and although, sometimes in a few days, more often only after a week or two have elapsed the bacteriologist is able to report that the wound is surgically clean, my experience is that simple suture undertaken then is likely to be followed by something disappointingly short of primary union Nor is this to be wondered at when we remember how real a fact latent sepsis is, how, many months after a wound has healed, forcible movements or even simple massage may light up infection—suppuration, or tetanus, or even gas gangrene—it is easy to understand that, during the suppuration period, organisms will have had time to "dig themselves in" to the deeper tissue cells from which they are able to sally forth to upset the healing process in the stitched up wound

The B I P P method and its limitations.—Morison's B I P P method aims at introducing into a wound, admittedly infected, chemicals which for a long period continue to generate disinfectant agents, which experience has shown will effectually keep under the infection and allow healing to proceed In many cases the results are excellent, but commonly some area of the wound has to heal by granulation Occasionally pus collections form and require draining and whenever there is much loss of tissue and consequent tension on the stitches these are likely to cut out and allow the skin edges to gape

The Bradford method.—The method which experience has led me to adopt includes something of the B I P P method along with the Carrel Dakin treatment, and may now be described in detail.

I *Wound Sterilisation*

Most of the wounds as they arrive from France have already been opened up Where pus is pocketing in the track of a through and through wound, or beneath or between two adjacent muscles or where loose bone fragments or other devitalised or foreign bodies are present an anæsthetic must be given and the wound cleansed and laid freely open *The skin incision whenever possible should extend the whole length of the wound* A wound with a narrow bottle neck opening may have a Carrel tube in it and Dakin's fluid instilled into its cavity, but it is nevertheless not being treated by Carrel's method

The ideal Carrel wound is a basin which can easily be kept full to the brim with Dakin's fluid Such a wound would be a deep flesh wound in the front of the thigh Into the depths of such a wound are passed one or more tubes of about ¼ inch calibre of which the distal end is closed by a ligature and which has a few tiny side holes punched in that part of the tube which lies in the wound The tubes are connected with a reservoir containing Dakin's fluid hung over the bed and every two hours the nurse releases a clip and allows just enough fluid to escape to fill the wound to the brim without allowing any to run over

Posture can often be utilised to make it easier to apply the proper treatment—e g a man with a wound on the outer surface of his right thigh can be made to lie comfortably on his left side—so that his wound is uppermost And it is remarkable how contentedly a man with a wound of the buttock will lie for days together on his face

When the wound is so situated that it cannot be made to hold fluid basinwise gauze 8 to 12 thicknesses is cut exactly the shape of the wound but about ⅛ inch less in diameter so as to leave a tiny red margin all round when the gauze is tucked into the wound The Carrel tube is placed deep to the gauze which is saturated with fluid every two hours

In some of the hospitals in France an elaborately constructed wool and tissue covering is pinned around the affected limb Personally I favour extreme simplicity of dressings, a cage over the wounded part and no dressing but simply a dressing towel placed so that it keeps dust and flies from the wound but not touching the wound itself since if it is allowed to do so it will absorb fluid from the wound surface and so tend to defeat the object sought A really careful nurse who understands the principles of the treatment can generally manage to regulate the supply of Dakin's solution, so that there is no overflow to irritate the skin, if fluid does run over and threaten to produce dermatitis the simplest preventive is boric ointment melted in a glue-pot and painted with a brush on to the threatened skin

The bacteriological examination.—Every third or fourth day a platinum loop-full of the discharge is taken from the wound surface wherever it looks least healthy and spread thinly and *uniformly* evenly on to a microscope slide It is fixed by heat and stained (our bacteriologist Dr R Honeyburne finds brilliant-green a very satisfactory stain differentiating well between nucleoli and organisms) and examined with a 1/12 inch oil immersion lens The organisms on ten fields are counted and I make it a rule not to attempt to close a wound until two reports of an average of less than three organisms per field have been returned.

II *Wound Closure*

Flesh wounds.—1. The skin around the surgically clean wound is cleansed in the ward by the nurses, much as the skin prior to a clean operation is but only so far as it can be done without causing pain In the theatre under general anæsthesia the skin is vigorously rubbed over with biniodide of mercury in spirit (1 500) 2 The edges of the wound are trimmed with a scalpel evenly all round—rather less than ¼ inch of healing edge being removed but in wounds which are tending to scar over all the scar tissue is cut away 3 The granulations are thoroughly curetted. 4 The skin edges are undercut, even in a small wound where the edges will easily come together they are undercut, as I find that much more accurate apposition is thus obtained In large wounds, particularly with much loss of tissue, extensive undercutting is done 5 Any definitely bleeding vessels are tied (oozing does not matter), the whole wound area is swabbed with methylated spirit and a little B I P P —never more than an eggspoonful and in a smallish wound half that quantity—is scrubbed into the raw surface with the gloved fingers 6 Wherever possible any raw muscle surface is closed by bringing together the edges of the deep fascia (exposed by the under-cutting) with a running stitch of stout catgut 7 Thick silk sutures (No 5 pedicle silk boiled and soaked for 48 hours in tinct iodi) are passed through the skin and the deep layers of the wound at intervals of about ¾ inch and tied tightly so that no "dead cavity" is left Where there is tension on the part I find the most useful stitch a combination of a mattress with a simple surgical stitch The mattress stitch is passed widely and deeply and pulled tight at one corner with a single loop, the needle is then passed through the skin edges, and on tying the final surgical knot wide apposition of the deep structures and accurate approximation of skin edges are obtained. 8 A continuous catgut stitch is used to complete the coaptation of the skin edges 9 The skin is cleaned and smeared over with Moynihan's cream [1] and a simple dry gauze and wool dressing applied

The dressing is not touched for 14 days It is then removed, any discharge is wiped away and Moynihan's cream and another dry dressing are applied. At the second dressing a week later the stitches are removed, and never before.

Of 10 cases so treated I find that 7 or 8 will have healed practically by first intention 1 or 2 will have gaped a bit at one part leaving a superficial granulating area, and the tenth—practically always one where there has been loss of tissue and consequent tension on the stitches—will be a failure at any rate in large part, and will require to be done again, or perhaps skin grafting will be necessary

It is not simply that healing is by this means accelerated and frequency of dressings enormously reduced, lineal non-adherent scars take the place of wide adherent disabling scars I am sure that for years to come it will be our duty to reduce disability in war pensioners by excising the painful scars which limit movements and reduce earning capacity and I have already performed a considerable number of such operations with the happiest results

Compound fractures of long bones.—In cases of recent wounds with compound fractures I do not attempt Carrel's treatment but adopt Rutherford Morison's treatment because by so doing the limb can at once be fixed in a dressing which does not require to be changed for a fortnight, and so a great amount of suffering is done away with The following is a summary of Mr Morison's own description[2] 1 Under an anæsthetic clean the skin 2 Open the wound freely, and, if possible, sufficiently to permit of inspection of its cavity Cleanse the cavity with dry sterile mops, Volkmann's spoon, &c, and remove all foreign bodies 3 Mop the surrounding skin and the wound cavity with methylated spirit 4 Rub B I P P into all parts of the wound with dry gauze, removing any excess[3] 5 The wound is then stitched with deeply placed iodised silk sutures, and a large dressing of iodoform gauze and sterile wool bandaged on The dressing is not removed for a fortnight If there is much discharge the outer dressing may be removed and a clean pad applied

---

[1] A mixture consisting of as much bismuth carbonate in 1 1000 watery solution of HgI as will make a thick paste

Frequently when the dressing is taken off the discharges, sometimes evil smelling, are found plastered all over the skin, producing a most unpleasant appearance But when the discharge has been bathed away the wound is usually found to be to a large extent healed, a narrow strip of superficial granulations remaining to be dressed once in every five or six days

It approaches the miraculous to see a limb pouring foul pus from a wound at the bottom of which lies a segment of humerus or of femur smashed into a multitude of spiculed fragments, and every attempt at dressing which causes the patient untold agony, bandaged (if it is an arm) to the chest wall or (if it is a femur) fixed in a Thomas's splint, and after having been left untouched for a fortnight uncovered and found to show only a superficial granulating wound from which commonly the 14 days' discharge has been less in amount than that of one day previously Not only is there saving of nursing labour and of pain to the patient and the conversion of a compound into a simple fracture, but the healing of soft parts takes place without that terrible formation of contracting scar tissue which, by compressing the nerves, produces so frequently a helplessly paralysed limb

Compound fractures of short bones —In cases of smashed tarsus or carpus the missile has often "mushed" up one or more bones An X ray plate may show no obvious bone injury, but unhealthy granulations will soon pout from a relatively small skin wound, the hand or foot becomes painful and tender, there is some fever and more or less swelling of surrounding soft tissues Under an anæsthetic the wound (or, if there are two, the uppermost one) is opened up, the pulped up bony tissue is scraped away thoroughly, and the wound made as basin shaped as possible, the skin wound being enlarged until it is larger than any transverse diameter of the hole in the bones One or more Carrel's tubes are inserted, and the wound cavity is kept constantly filled with Dakin's solution The hole quickly becomes lined with healthy granulations, in a comparatively short time the wound has closed in and healed over The majority of the patients get moveable joints I have seen almost normal function after removal of the astragalus and part of the os calcis

Chronic necrosis with sinuses —There remains to be considered the case in which a fracture of a long bone has united, but a sequestrum is locked up in the callus or some less definite area of necrosed bone keeps up the discharge of pus from one or more sinuses The first case I treated by the Carrel method may be described as a typical example

A man was admitted to the Bradford War Hospital at the end of 1916 suffering from a badly smashed femur The wound was bipped and the fracture united, and the man was sent to an auxiliary hospital walking on crutches A sinus appeared and continued to discharge pus even after a fairly large sequestrum had been removed At Sir B G A Moynihan's suggestion an extensive operation was performed A 10 inch incision was made in the line of the femur, through the old scar on the front of the thigh The incision was carried down to and through the periosteum and the soft tissues were stripped back from the bone All the bony irregularities about the seat of fracture were freely chiselled away until the exposed section of femur formed a smooth, regular floor of a large basin like cavity capable of holding several ounces of fluid A sequestrum 3 in long was found encapsuled in the new bone and removed The skin was stitched back on either side, so that the wound remained funnel shaped It was treated on Carrel lines, being filled up with Dakin's fluid every two hours In this case no tubes were used the limb was adjusted with pillows until the wound margins were level and the fluid was poured in every two hours to keep the "basin" full

In less than three weeks the bacteriologist was able twice to report the wound surgically clean Under ether the soft tissues were freed from the bone, a little B I P P scrubbed into the raw surface and thick silk sutures used to bring together the whole thickness of skin and muscles over the bone The first dressing was done 14 days later and almost primary union found to have taken place A fortnight later a linear scar remained and the soft tissues were moveable over a smooth bone surface

Such results as these make one feel that a new era has arrived with regard to the treatment of infected wounds and that surgeons will never again allow wounds to go on suppurating, satisfied with doing nothing to induce them to heal beyond draining and dressing them

In conclusion I have to thank Lieutenant-Colonel W Wrangham for permission to describe the work done at the Bradford War Hospital

STUDIES IN WOUND INFECTIONS

ON THE GROWTH OF ANAEROBIC BACILLI IN FLUID MEDIA UNDER APPARENTLY AEROBIC CONDITIONS

(*From Inoculation Department, St Mary's Hospital*)

IT has been known for some years that the addition of a piece of animal or vegetable tissue to any fluid media had a beneficial action on the growth of the anaerobic bacteria

Tarozzi was the first to point out the advantage of such a procedure, the *sine qua non* of his method being the addition to the fluid media of a piece of animal tissue, usually kidney or testicle, taken as soon after the death of the animal as possible This method, in spite of the trouble involved in obtaining such tissues perfectly sterile, was used extensively by Noguchi in isolating various forms of spirochætes

Later Ori and Wrzosek showed that the substitution of a piece of potato or other vegetable tissue for the animal tissues used by Tarozzi was followed by equally satisfactory results, and further, that sterilisation by heat did not interfere with the beneficial effect of such a procedure

Wright and Dreyer working in Boulogne, employed as a routine method for growing anaerobes tubes of broth to which a piece of potato had been added previous to sterilisation, and by such methods obtained abundant cultures of all the prevalent anaerobes isolated from wounds without taking any further precautions for obtaining anaerobic conditions, it was even found that growth occurred when a stream of oxygen was passed through the fluid portion of the media

The usual explanation of such results has been that the animal or vegetable tissues contained some body capable of acting as a reducing agent That living tissues, both animal and vegetable, act as reducing agents is a well recognised fact, but it is unlikely that a small pellet of potato after being autoclaved should be able to bind all the oxygen which would be constantly absorbed from the surface of the media

It was therefore decided to confirm some of the experiments that had been carried out by different workers and to try to ascertain if any other explanation could be found for these somewhat surprising results

---

[3] B I P P is made as follows Iodoform 16 oz bismuth subnitrate 8 oz liquid paraffin 8 oz, or a sufficient quantity to make a firm paste The powders are mixed together in a mortar and the paraffin incorporated

Experiments with Vegetable Tissues

In order to confirm the results obtained by Wright and Dreyer showing that all the usual anaerobes found in wounds give an abundant culture when a small piece of potato or other vegetable is added to the broth before sterilisation a number of broth tubes were taken, to each of which a small cube cut from a potato was added after which they were sterilised in the autoclave Into these a variety of anaerobic bacilli were planted, and the tubes were then incubated at 37° C without any further precautions to produce anaerobic conditions The tubes were examined for growth after intervals of 24 and 36 hours The results are given in Table I

TABLE I

No	Laboratory name of culture	Type of bacillus	Result
1	Grout I	*B perfringens*	Copious growth after 24 hours
2	Hancock I		
3	Boone II	B of malignant oedema	
4	McArdle E	" "	"
5	Tholby III	"	"
6	McFadzean II	–	
7	McFadzean VII		"
8	Boone I	A non motile bacillus resembling *B perfringens* except in its fermentation reaction	"
9	Tholby IV	Gram negative bacillus with round terminal spore	" "
10	Tholby	Bacillus resembling *B tetani*	" "
11	Boone III	Hibler IX type	Copious growth after 36 hours

This table shows that the addition of a small piece of potato to the broth before sterilisation enables cultures of the anaerobic bacilli commonly found in wounds to proliferate rapidly in the absence of any further procedures to produce anaerobic conditions

Further experiments showed that pieces of carrot, cabbage, or grape were equally efficacious as potato In addition to these substances flakes of bran were also employed, and an experiment was made in which different amounts of bran were added to the broth to ascertain if the growth varied with the amount of bran added This experiment was carried out in the following manner To a series of broth tubes, each containing 10 c.c of broth, varying quantities of bran were added After sterilisation in the autoclave each tube was planted with a loopful of broth culture of the bacillus of malignant oedema and then incubated at 37° C without further precautions as regards anaerobic conditions Examinations for the presence of growth were made at varying intervals The results are shown in Table II

TABLE II

Amount of bran added	Result after 18 hours	Result after 36 hours
1 flake	No growth	No growth
4 flakes	Slight growth	Abundant growth
10 flakes	Good growth	
Many flakes	Abundant growth	

This experiment shows that up to a point the more bran that was added the more copious and rapid was the growth It may here be noted that of all the various substances which were employed in the experiments detailed in this paper to promote the growth of anaerobic bacilli in broth cultures, bran appeared to be the most efficacious

Taking the result of these experiments into consideration, it was thought that some 'foodstuff" such as vitamines, might have been given up to the broth by the vegetable substances added to it which enabled the anaerobic bacilli to proliferate even when oxygen was present, in order to verify this experiments were made to ascertain if anaerobic bacilli would grow in broth to which an alcoholic extract of bran had been added

These experiments were carried out in several different ways For instance the alcoholic extract of bran was evaporated to dryness and small portions of the substance thus obtained were added to the broth or strips of sterile filter paper having been soaked in the alcoholic extract and then dried were placed in broth Again small quantities of the fluid alcoholic extract were added directly to the broth These various samples of broth were then planted with anaerobic bacilli and incubated under ordinary aerobic conditions

The results obtained by these experiments were conflicting In some cases the broths containing the alcoholic extract gave abundant growths of the anaerobic bacilli, whereas control broth tubes gave no growth In other cases, for instance that experiment in which filter paper impregnated with the alcoholic extract had been added to the broth, growth appeared equally abundant in a control tube to which a piece of untreated filter paper had been added, as in those which contained the treated filter paper It was also observed that growth occurred only in those tubes where a considerable mass of the solid alcoholic extract had been added or an extensive precipitate had been formed

Experiments with Inert Substances

Abandoning the idea that the growth of the anaerobic bacilli was due to the presence of any special 'foodstuff," it was decided to carry out experiments to ascertain if growth would occur when various inert substances were substituted for the vegetable tissues

In these experiments various porous substances, such as asbestos wool, cotton wool, lint, sponge, charcoal, chalk, cork, sand, cardboard, blotting paper, khaki cloth, and, lastly, a rusty nail, were each added to a series of broth tubes, which were then autoclaved Each series of tubes together with a control tube of simple broth, were then planted with an equal quantity of an anaerobic bacillus and incubated under ordinary aerobic conditions Examinations for the presence of growth were made after incubation had continued for 15 18, 24, 36 and 48 hours The results are given in Table III.

TABLE III

Figures indicate the number of hours the tubes were incubated before growth appeared

0 indicates no growth throughout the duration of the experiment

– indicates that this special portion of the experiment was not carried out.

Bacillus planted	Control tube of broth	Substances added to broth											
		Asbestos wool	Cotton wool	Lint	Sponge	Piece of charcoal	Piece of chalk	Piece of cork	Sand	Piece of card	Piece of blotting paper	Piece of khaki cloth	Rusty nail
B perfringens	0	15	15	36	15	24	18	24	24	48	0	24	—
B malignant oedema.	0	36	36	0	0	24	24	0	0	0	0	0	36
B butyricus	0	15	15	24	0	18	15	18	18	24	0	0	18
Pseudo-tetanus	0	38	36	36	0	36	24	0	48	0	0	0	—
Tholby IV	0	36	36	36	36	36	24	36	36	24	0	24	—

These results show conclusively that any porous inert substance when added to broth renders this medium quite as suitable for the growth of anaerobic bacilli, without any further precautions as regards anaerobic conditions being taken, as the addition of pieces of potato or other vegetable matter These facts can be most simply explained by assuming that the bacilli lodged in the meshes of the various substances are locally able to produce anaerobic conditions, in consequence of which they proliferate at first only in the interstices of the material but later also in the surrounding media

On studying this table more closely it is, however, to be noticed that none of the tubes containing pieces of blotting paper developed any growth, in these tubes the paper added consisted of a small unfolded slip of thin blotting paper Again, it is noticeable that growth developed only in two out of the five tubes containing pieces of khaki cloth Owing to the small amount of this material available only a very small piece could be added to each broth tube, and during the process of sterilisation the woollen strands became so unravelled that none of these tubes contained a close meshed mass comparable to that seen in the tubes containing the asbestos wool

From these observations it appeared probable that neither in the case of the pieces of unfolded blotting paper or of the minute pieces of unravelled khaki cloth were suitable interstices formed to enable the anaerobic bacilli to produce the conditions necessary for their growth It was therefore decided to carry out a further series of experiments in which different amounts of asbestos wool were added to the broth in order to ascertain if a closely packed mass of this material afforded more suitable conditions for the growth of the anaerobic bacilli than a smaller and more open meshed piece of the same material This experiment was carried out as follows —

Two strains of anaerobic bacilli were taken, one of which had been demonstrated to be a very strict anaerobe, the other being capable of proliferating under less strict conditions of anaerobiosis Each of these bacilli were then planted into two culture tubes, the one containing ordinary broth, the other broth to which a quantity of sterile asbestos wool had been added The quantity of asbestos wool added to these tubes was varied In the tube in which the strict anaerobe was planted a larger and more closely packed mass of this wool was placed than in the tube in which the bacillus capable of growing under less strict anaerobiosis was planted These tubes were incubated without further anaerobic precautions and examined after 24 hours, when it was found that the strict anaerobe showed abundant growth with much gas formation, while the less strict anaerobe, having only the protection of a small and open meshed piece of asbestos wool, gave only slight growth and very little gas formation

This experiment shows that the amount and consistency of the inert substance added to the broth is an important factor in making the conditions suitable for the growth of anaerobic bacilli

Experiments with Capillary Glass Tubes

In order to test further the soundness of the theory put forward above—namely, that growth takes place at first in the interstices of the mass of inert material, an experiment was made in which a hair fine capillary glass tube was placed in the broth Such a hair fine glass tube would represent in its simplest form a single interstice in a mass of asbestos wool, and if the theory put forward above was correct the growth should commence in this tube and only later spread to the surrounding media. A further advantage of such an experiment was that even in the finest capillary tube growth could be recognised by the formation of minute bubbles of gas These experiments were carried out as follows —

A series of broth tubes were taken and planted with anaerobic bacilli, each variety of bacillus being planted in equal quantity into two tubes Into one of the tubes, in the case of each bacillus, a hair fine glass capillary open at both ends was placed, the other tube being kept as a control The tubes were then incubated and after varying intervals examined for growth In the case of the control tubes no growth was ever noticed but in a certain proportion of those containing the hair fine capillary tubes growth appeared after an interval varying from 24 to 48 hours That this growth commenced inside the capillary tube was shown by the appearance of minute bubbles of gas inside the tube before any evidence of growth could be detected in the surrounding media

That it was only a proportion of those cultures containing capillary tubes which gave growth can be explained by assuming that, as these tubes would only contain a fraction of a cubic millimetre, and that, as the anaerobic bacilli were not planted out very thickly, a proportion of the capillary tubes would not contain even a single living bacillus

In Table IV a series of successful experiments are given which show that all the anaerobic bacilli commonly found in infected wounds are capable of growing in broth to which such a hair fine capillary tube has been added without any further precautions being taken to produce anaerobic conditions

TABLE IV

Laboratory name of bacillus	Type of bacillus	Broth control	Broth + capillary tube
Grout I	*B perfringens*	0	Good growth in 36 hours

Tholby II	Pseudo tetanus	0	48
Tholby IV	Gram positive acid forming bacillus	0	36
Cullingford	Putrefactive bacillus	0	24

Other Experiments Summary of Results

These results show that the growth of the anaerobic bacilli takes place at first inside the confined spaces, however in order to show that anaerobic conditions were produced in the spaces the following experiments were made

Tubes of glucose broth were tinted with an aqueous solution of methylene blue, and a suitable mass of asbestos wool was then added After sterilisation these tubes were planted with *B perfringens* and incubated under the usual aerobic conditions Rapid growth occurred, which was quite apparent after four hours, and it was noticed that the broth was completely decolourised in the immediate neighbourhood of the asbestos wool On shaking the tube, however the colour returned to its original density This reduction and reproduction of the colour could be produced at intervals for several hours

This experiment was repeated with broth coloured with sulphindigotate of soda with exactly similar results and it was also found that some of the bacilli which were not very strict anaerobes were able to grow in this broth without any asbestos wool being added to it (especially when they were thickly planted) and that here also the decolourisation of the sulphindigotate took place at the bottom of the tube, where a large amount of bacilli were collected It therefore seems certain that the anaerobic bacilli are either able to absorb oxygen rapidly or during their growth produce some very strong reducing substance which rapidly removes any oxygen that may be present

Further experiments in which a similar technique was employed showed that during their growth the anaerobic bacilli were able to remove any oxygen from the culture media much more rapidly than many of the aerobic bacilli

The above experiments show that the anaerobic bacilli are capable of proliferating freely in broth to which a piece of any inert porous substance has been added The most convenient substance is a small pledget of asbestos wool, owing to the ease with which it can be sterilised by holding it in the flame of a Bunsen burner until it is red hot

These experiments also show that the growth takes place first in the interstices of the porous material, that in all probability anaerobic conditions are produced in these minute spaces, and that later the oxygen present in the surrounding broth is removed during the growth of the bacilli entangled in the porous mass

Experiments with Substances under Anaerobic Conditions

Lastly experiments were made to ascertain if a more rapid and more certain growth of the anaerobic bacilli could be obtained if in addition to the ordinary methods for obtaining anaerobic conditions a piece of inert porous substance was added to the broth into which the bacilli were planted The details of these experiments are as follows —

Experiment 1 —Six small test-tubes were taken and into each an equal quantity of sterile serum was placed and each tube was then planted with an equal quantity of *B perfringens* emulsion Into three of these tubes a small compact pledget of asbestos wool was introduced, the other three tubes being kept as controls After this all the six tubes were sealed with a layer of melted vaseline and incubated at 37° C After three days' incubation it was found that no growth could be demonstrated in any of the three control tubes, whereas all the tubes containing the asbestos wool showed abundant growth The absence of growth in the control tubes was probably due to the now widely recognised fact that *B perfringens* will only proliferate in serum when the implantation is a heavy one

Experiment 2 —A broth culture of the bacillus of malignant œdema was diluted by ten fold steps to 1 in 1,000 000 dilution Twenty c mm of each of these dilutions were then planted into tubes of (i) simple broth, (ii) broth to which a small piece of potato had been added, (iii) broth into which a pledget of asbestos wool had been placed These tubes were then placed in the anaerobic apparatus described by McIntosh and Fildes and incubated at 37° C The results obtained at the end of 24 and 48 hours are given in Table V

TABLE V*

Media employed	Result after 24 hours	Result after 48 hours
(i) Broth	No growth in any tube	Growth in tubes planted with all dilutions up to 1 in 100 000
(ii) Broth + potato	Growth in tube planted with culture diluted 1 in 10	
(iii) Broth + asbestos wool	Growth in tubes planted with culture diluted 1 in 10 and 1 in 100	Growth in tubes planted with all dilutions up to 1 in 1 000 000

These experiments demonstrate that anaerobic bacilli will grow both more rapidly and also from a smaller implantation when *in addition to the usual anaerobic conditions* some porous substance such as potato or asbestos wool is added to the culture medium

AN UNUSUAL COMPLICATION OF LAPAROTOMY FOR GUNSHOT WOUND

BY WILLIAM H JOHNSTON, B A., M.D , CH.B ,
CAPTAIN ROYAL ARMY MEDICAL CORPS

IN the following case of gunshot wound of the abdomen with perforations of intestine, which were sutured, diffuse purulent peritonitis occurred as a complication, consequent upon rupture of an abscess in the anterior abdominal wall. Treatment by the Carrel Dakin method was carried out, and resulted in recovery

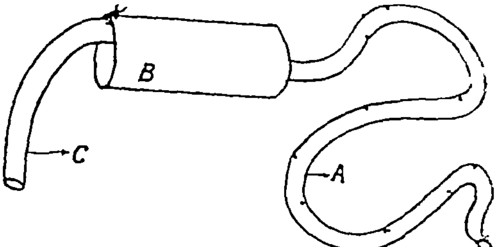
The patient, a soldier of a rifle regiment aged 26, was hit in the abdomen by a rifle bullet on April 4th, 1917 He was admitted by a field ambulance on the same day, where after the administration of morphia, he was marked for urgent attention, and transferred immediately to a casualty clearing station There also on the same day his abdomen was opened by a paramedian incision Five holes in the small gut and two tears in the mesentery were sutured. No other injury was found, nor any foreign body He had a mild peritonitis for 24 hours, but progressed satisfactorily

Thirteen days later, on April 17th, the patient was transferred to a base hospital On admission his condition was good, temperature being 97 6° F and pulse 72. There was localised tenderness over the middle of the scar, otherwise the condition of the abdomen was excellent He complained of a little pain referred to the area of the operation incision. There was no rigidity and the abdomen moved freely on respiration

Suddenly, on the night of April 17th, about 10 P M., he was seized with acute abdominal pain He vomited frequently His pulse rose to 120, his temperature at 6 A.M. on April 18th was 100° On examination there was general tense rigidity, considerable tympanites, great tenderness but no appreciable dullness in the flanks. At 8 A.M. he exhibited all the signs of a diffuse peritonitis, the vomiting continued, and his condition became critical.

Operation, 9 A M , April 18th The original incision was opened An abscess cavity full of thick greenish yellow pus was found on the posterior sheath of the rectus, and extending between the divided muscle This had tracked backwards and burst into the peritoneal cavity through the original line of incision The abdomen contained some pints of a thin greenish purulent non odorous fluid. There were flakes of lymph widely diffused upon the intensely congested bowel From this fluid pure cultures of *Staphylococcus pyogenes* a short-chained streptococcus, and *B coli* were isolated

FIG 1



The Carrel technique modified for the peritoneal cavity A, One end of the Carrel tube of which 6-8 in are left inside the abdomen. B Outer drainage tubing ¾ in in diameter C, Outer end of Carrel tube connected to irrigator

The patient's condition was so grave that it precluded any extensive manipulation of the bowel No perforations were found nor was there any sign of the escape of intestinal or other visceral contents After copious irrigation with Dakin's fluid four drains of ¾ inch tubing 2 inches long were inserted one in each flank, into the right and left paracolic gutters and one into each groin (Figs 1 and 2.) These were stitched in position and through each a Carrel tube was introduced into the abdominal cavity so that about 6 to 8 inches of the perforated tube lay inside the abdomen The flank tubes were planted into the paracolic gutters The groin tubes were allowed to lie free amongst the coils of bowel. In turn each Carrel tube was sutured to the wall of the outer large drainage tube. The excess of Dakin's fluid was [illegible] mopped out from the pelvis The original abdominal incision was then closed by interrupted through [illegible] sutures including all structures in one. A small tube was introduced into the abscess cavity in the rectus sheath. At the time of the operation the incision wound was also "Carrelled." The anaesthetic administered was warm open ether and subcutaneous transfusion with saline (about 3 pints) was carried out during the operation. On completion of the operation, which lasted about 25 minutes, the pulse was 15[illegible] and the temperature subnormal. The patient's condition was then very grave.

In the ward the patient was put in the Fowler position. Subsequently irrigation with [illegible] and tubing connected up to each of the four small Carrel tubes was carried out three-hourly for the first two days and four-hourly for the next five days. Thereafter the irrigation was gradually slackened off from six-hourly to eight-hourly flushings. The total quantity of Dakin's fluid used at each flushing was from about 50 to 60 c.c.

Pulse and Temperature During First Six Days

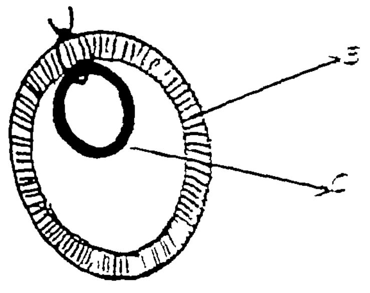
* First day shows reading after operation.

On the evening of the day of the operation the patient's temperature was subnormal and remained so until the evening of April 21st (three days). The change in pulse was remarkable (see table). It registered 15[illegible] in the morning after the operation and 11[illegible] in the evening. The temperature chart was equally striking. The first rise above normal after the operation occurred on the evening of April 21st when his temperature reached 99°. The pulse rapidly fell to normal, regained its tone, and from the day after the operation ran steadily at about 72 to 80. From April 23rd he ran a slight evening rise of temperature (usually 99-99.2°) which continued for [illegible] days. During this time, in the mornings, the temperature was always normal. On May 15th his temperature remained steadily at normal and his pulse was then regularly about 72. Only on one occasion did the temperature rise above 100°—namely, on the evening of April 30th—when the pulse also rose to 104. The cause was obviously a localised collection of pus, which was not draining efficiently through the laparotomy wound.

FIG. 2



Explanatory section on a larger scale

Dressings.—Patient was dressed twice daily for two weeks, and thereafter once daily. Owing to local infection from the abscess all the stitches had gradually to be removed from the laparotomy wound by the end of the third day. Pocketing occurred on both sides in the rectus sheath. Pockets were opened by sinus forceps and Carrel tubes were introduced into their farthest extremities. The abdominal parietes were strapped effectively with strips of 2 inch adhesive plaster applied in a laminated manner from behind the back, circling around the abdomen and crossing the laparotomy wound transversely, spaces being cut in the adhesive to allow for drainage and the re-insertion of the Carrel tubes. These strips had to be reapplied once daily

At each dressing the Carrel tubes leading inside the abdomen were gently twisted round and slightly withdrawn through the outer large drains. They were then fixed by safety-pins as before, and the Dakin fluid was then turned on through the connexions for a few seconds. It was observed that on doing this in the first half-dozen dressings a copious amount of pus was washed out through the large drains. By gently moving the Carrel tube the coagulum at the inner end of the large drain was dislodged, and any free exudate was then washed out by the fluid from the Carrel tube. Gradually each day the Carrel tubes were drawn out, until at the end of 18 days (May 6th) all four were removed and the four small drainage-wounds allowed to close.

Calomel, gr 1/6, was administered six hourly for two days Thereafter the patient obtained a natural action of the bowels and only once had an attack of colic, due probably to an indiscretion of diet On April 20th, two days after the operation, patient's blood was examined and the count showed as follows Polymorphonuclears, 52 5 , eosinophiles, 5 5 , granular basophiles, 3 0 , large hyalines, 12·0 , and lymphocytes, 27 0 per cent Leucocytes, 20 000

Thirty three days after the operation, having made an excellent recovery, patient proceeded to England.

Remarks —To sum up, the case appears to us to present certain points of interest 1 Patient had already, prior to the operation for generalised peritonitis, undergone a laparotomy for a gunshot wound, with suture of several holes in the gut and mesentery 2. At the time of the second operation his condition was undoubtedly grave 3 The bacteriological findings at the time of the second operation pointed to a virulent infection 4 His leucocyte reaction determined on the second day after his second operation pointed to a strong resistance

There is no doubt that the bursting of the abscess in the rectus sheath was the cause of the diffuse peritonitis There may be room for doubt that the abscess was a suture abscess There is, however, little doubt that the infection *first developed* in the abdominal wall, originating either from within from contamination of the perforated gut, or from without from skin infection

The ultimate excellent recovery, without for the moment considering Carrel Dakin treatment, pointed to the fact that the first operation had been successful so far as repairing lesions in the gut was concerned One is quite aware that even the worst cases of peritonitis sometimes go straight ahead after operation, but the clinical picture and the whole facts of the case point strongly to something more than coincidence here, and suggest the further invest
the Carrel technique applied to the peritoneal cav

immunity developed after two or more weeks is the same for single as for mixed emulsions. From the clinical stand point, however, Coppinger and Gibson found that when the triple vaccine was used the reaction begins earlier and is more intense than when the single typhoid emulsion is injected

During an acute attack of paratyphoid fever in a man previously inoculated with typhoid vaccine the inoculation typhoid titre is very frequently increased[1] The figures we include in Table III suggest that an increase in the inoculation typhoid titre occurs also in the presence of inoculation agglutinins induced by the injection of para A and B bacilli In 310 men in whose blood there appeared all the three agglutinins and who had not been the subjects of typhoid paratyphoidal infection, the typhoid units yielded a larger percentage of high units than were met with in 617 other men who had been inoculated with typhoid bacilli only

Whether the typhoid agglutinin interacts similarly with the paratyphoid agglutinin production is a problem upon which we cannot offer any evidence at the moment, but the subject seems worthy of inquiry and we have accordingly instituted experiments towards its elucidation

Agglutinin Units following the Injection of Triple Vaccine in 356 Men

The findings so far discussed relate chiefly to the inter action of agglutinins There remains still the broader question of the general bulk results which have been yielded by sera obtained from men inoculated with the triple typhoid para. A and B vaccine Here we have considerable difficulty in presenting any complete survey as it has not been possible always to obtain a precise account of the type of vaccine injected Making use however of the general statement that the triple vaccine came into widespread employment in the early days of 1916 we have been able to present a rough account of the agglutination units determined Had we been dealing with the acute phases of the diseases which caused the home coming of the men, we should have found it more easy to place certain anomalous instances within definite categories It was necessary to rely on experience and intuition in these cases to a greater extent than we care to do, but it seems worth while, perhaps, to attach Table IV as a rough estimate of the success and failure of response to the triple vaccine The negative findings are placed under the heading of "Less than 3" units of agglutinin although the majority of these failed to give agglutination in dilutions of 1 in 10 serum Speaking generally, the typhoid negatives are fewer than those met with after the injection of the single vaccine, while those following para A and B are more numerous

We thank Lieutenant-Colonel J P Bush, C M G, Lieutenant-Colonel J Michell Clarke, and the whole of the staff of the Second Southern General Hospital, for the facilities they have so kindly provided

Summary

1 Additional observations upon the inoculation agglutinins following injection of killed typhoid bacilli are recorded They confirm previous statements

2. The agglutinin content after injection of the triple vaccine shows the response to be as persistent as when the single vaccine is employed The units for paratyphoid A are the lowest next comes paratyphoid B and finally typhoid bacillus

3 When compared with the results following inoculation with *B typhosus* only the use of the triple vaccine is associated with an increased number of typhoid agglutinin units

4 These findings in bulk confirm for man the observations which Dreyer and Ainley Walker record in their

adhesive to allow for drainings and the re insertion of the Carrel tubes These strips had to be reapplied once daily

At each dressing the Carrel tubes leading inside the abdomen were gently twisted round and slightly withdrawn through the outer large drains They were then fixed by safety pins as before, and the Dakin fluid was then turned on through the connexions for a few seconds It was observed that on doing this in the first half dozen dressings a copious amount of pus was washed out through the large drains By gently moving the Carrel tube the coagulum at the inner end of the large drain was dislodged, and any free exudate was then washed out by the fluid from the Carrel tube Gradually each day the Carrel tubes were drawn out, until at the end of 18 days (May 6th) all four were removed and the four small drainage wounds allowed to close.

Calomel, gr 1/6, was administered six hourly for two days Thereafter the patient obtained a natural action of the bowels and only once had an attack of colic, due probably to an indiscretion of diet On April 20th, two days after the operation, patient's blood was examined and the count showed as follows Polymorphonuclears, 52 5 , eosinophiles, 5 5, granular basophiles, 3 0, large hyalines, 12 0, and lymphocytes, 27 0 per cent Leucocytes, 20 000

Thirty three days after the operation, having made an excellent recovery, patient proceeded to England.

Remarks —To sum up, the case appears to us to present certain points of interest 1 Patient had already, prior to the operation for generalised peritonitis, undergone a laparotomy for a gunshot wound, with suture of several holes in the gut and mesentery 2 At the time of the second operation his condition was undoubtedly grave 3 The bacteriological findings at the time of the second operation pointed to a virulent infection 4 His leucocyte reaction determined on the second day after his second operation pointed to a strong resistance

There is no doubt that the bursting of the abscess in the rectus sheath was the cause of the diffuse peritonitis There may be room for doubt that the abscess was a suture abscess There is, however, little doubt that the infection *first developed* in the abdominal wall, originating either from within from contamination of the perforated gut, or from without from skin infection

The ultimate excellent recovery, without for the moment considering Carrel Dakin treatment, pointed to the fact that the first operation had been successful so far as repairing lesions in the gut was concerned One is quite aware that even the worst cases of peritonitis sometimes go straight ahead after operation, but the clinical picture and the whole facts of the case point strongly to something more than coincidence here, and suggest the further investigation of the Carrel technique applied to the peritoneal cavity

INOCULATION AGGLUTININS

BY I WALKER HALL, M D VICT ,
HONORARY CONSULTING PATHOLOGIST TO THE SECOND SOUTHERN GENERAL HOSPITAL PROFESSOR OF PATHOLOGY BRISTOL UNIVERSITY
With the Assistance of
I HILES, M SC , AND F NICHOLLS

(*Report to the Medical Research Committee*)

IN an earlier communication we recorded the agglutination titres observed in some individuals who had been inoculated previously with antityphoid vaccine We also gave an account of the interaction of inoculation and infective agglutinins during the acute phases of paratyphoid fevers, and stated the results of concomitant absorption experiments which supported the views of Grattan Wood, Harvey, Dreyer and others, that the presence of infective paratyphoid agglutinins is associated with a tissue stimulation which brings about a rise in the agglutinins induced by the prior injection of killed typhoid bacilli [1]

The advent of a number of convalescents who had been inoculated with the triple typhoid, para A and para B vaccine, afforded an opportunity for determinations of the extent and persistence of the inoculation agglutinins thereby occasioned and permitted an inquiry into their interaction

The results now appended seem to suggest that the inoculation agglutinins which appear in the blood after the injection of dead typhoid, para A and para B bacilli tend to raise the titre for typhoid bacilli above that which follows when typhoid bacilli alone are employed, and that these titres are specific absorption titres and not due to co-agglutination

Methods —The methods throughout were precisely the same standardised procedures as those stated in our communication to the *Journal of the Royal Army Medical Corps* in September, 1916

Inoculation Agglutinins for B Typhosus *only*

In 272 additional cases the single typhoid vaccine had been given and the results allowed comparison with similar findings in a further 77 cases inoculated before 1916, and another set of 268 cases examined in 1915–16 (Tables I and III) The figures in each lot are somewhat similar, although those for 1916 exhibit a larger number of negatives and a higher percentage of units over 650

Inoculation Agglutinins for B Typhosus *and* B Paratyphosus A *and* B

In Table II the titres obtained from the blood of 310 convalescents are incorporated These men had all been injected with the triple vaccine It will be seen that the units for *B typhosus* show a larger number of higher positives than those found when the single vaccine was injected (Tables I and III) The para. A and B units differ considerably, those of para A being uniformly lower than the para *B* but in both instances the extent and persistence of the agglutinative capacity are greater than what we had been led to expect from previous animal and human experiments [4 1]

The question, therefore, arises as to the respective parts played by the interacting stimuli emitted by the three types of bacterial protein It is generally accepted that during infection, and also after inoculation with para. A bacilli, the agglutinin response is meagre and does not persist for a long period, while both typhoid and para B infections and injections evoke a response in agglutinative capacity which is high and continued The figures we now present however denote a considerable amount of agglutinin content for paratyphoid A and an apparently good immunity at the end of 12 months Is this difference between the experimental infection and inoculation agglutinin and the specific inoculation agglutinin following injections of triple vaccine an expression of the group stimulation of the tissues by the action of the cleavage of dead typhoid or para B bacilli, or due to some other factor? The answer to this query might confirm the practice of combining the three emulsions at one injection or point to the advantages of single and separate injections We hope to bring forward some evidence bearing upon this problem in a later communication

The Interaction of the Typhoid and Paratyphoid Agglutinins

The response to the injection of single vaccines is said to be more rapid than that which follows inoculation with a mixed vaccine This has been established by Castellani for typhoid and paratyphoid bacilli [2] and by Freeman for typhoid and cholera organisms [3] But the extent of

Reviews and Notices of Books.

The Thyroid Gland in Health and Disease By ROBERT MCCARRISON M D R.U I D Sc Belf., F R.C P Lond , Major, Indian Medical Service , Lauréat de l'Académie de Médecine Paris With numerous illustrations London Baillière, Tindall, and Cox. 1917 Pp 286 Price 12*s* 6*d* net

FROM the time of Hippocrates and Aristotle onwards impure drinking water has been held by the majority of physicians to be the cause of goitre But it is only within comparatively recent years that we have approached a precise knowledge of the ultimate causes of disease of the thyroid parathyroid glands by the correlation of facts and inferences based upon the results of experiments upon animals, clinico-anatomical observations upon man, and epidemiological investigations It is a great satisfaction to recall the fact that many British physicians and physiologists have acted as pioneers in important contributions to our knowledge of the thyroid gland in health and disease, and we welcome this latest valuable pioneer work of Major McCarrison, which sets forth in a lucid comprehensive, and interesting manner a subject which he has studied experimentally, epidemiologically, and by clinico-anatomical observations for the past 14 years During this time he has contributed numerous original papers to medical journals and societies, including the Proceedings of the Royal Society, bearing upon goitre and allied subjects Major McCarrison speaks authoritatively as a physician of experience, and throughout all three parts into which the work is divided there is exhibited a most extensive knowledge of the literature

The first section deals with the thyroid and parathyroid glands in health , the second with the factors which cause them to depart from health , and the third with the morbid states of goitre and cretinism, tetany, *myxœdema*, and exophthalmic goitre In the appendix there are two series of cases showing the effects of intestinal antiseptics on goitre as well as a brief summary of the author's more noteworthy epidemiological and *experimental observations*

In reviewing this important contribution to medical literature we shall best serve the interest of the profession by briefly referring to Major McCarrison's conclusions regarding the causation, prevention, and treatment of endemic goitre, a subject of great importance seeing that "in India at the present time there are not less than five million persons afflicted with goitre while half a million is a low estimate of the number who suffer from its congenital manifestations " It was generally believed that permanent hardness of the water was the cause of goitre—e g , Derbyshire neck was *attributed to this* , while not denying that it may be to some extent a contributory *factor*, Major McCarrison's observations show that it is not an essential cause Within recent years the many theories as to the causation of endemic goitre have been reduced to the following (1) Chemical ingredients of drinking water, (2) geological peculiarities of the soil imparting to the soil a specific colloidal poison , (3) faulty nutrition , (4) living micro organisms The author *claims that his* experimental and epidemiological observations prove that living organisms are the essential cause of the disease and he puts forward the *following premises as* proof that fæcal contamination of the water supply by a living and *specific* micro-organism is the cause of goitre 1 In villages where goitre prevails this disease shows a steady increase in proportion to those conditions which increase *the impurity* of the water by fæcal contamination 2 He claims to have produced goitre experimentally in man by ingestion of the residue left on the *candle* of a Berkefeld filter after filtration of goitrigenous water This residue when boiled does not cause goitre 3 The administration of beta naphthol and thymol and other intestinal antiseptics may cause the disappearance of the goitre *in* young subjects 4 The researches on trout by Marine Lenhart and Gaylord demonstrate that fish confined in tanks one above the other on a single water supply exhibit an increasing thyroid hyperplasia in the series from above down 5 He claims to have produced goitre in rats and goats by feeding them on fæcal material from goitrous and even non goitrous subjects , also from cultures, aerobic and anaerobic. The anaerobic are the more potent 6 Congenital goitre with cretinism and parathyroid disease can be produced experimentally by feeding the mothers throughout *pregnancy* with these cultures Photographs of men and animals and photomicrographs of sections of the glands are given Finally, Major McCarrison claims that vaccines prepared from intestinal organisms are capable of causing the disappearance *of recent* cases of goitre when injected in appropriate doses at weekly intervals We are of opinion, however, that further observations will have to be made before the value of autogenous vaccines in the treatment of goitre can be accepted as proven With regard *to the infective organism* Major McCarrison claims that it lives in the soil of infected localities, and particularly in soil which contains a high proportion of organic matter of human or animal origin It seems that ' the great source of the disease is the infected individual, and that he is the producer, the reservoir, and the distributor or 'carrier' of the infecting agents " The author, therefore, implies that there is a specific organism capable of producing goitre, which exists in man living in districts where goitre is *endemic* This *organism* has not been isolated and obtained in pure culture , in fact, the observations on trout would seem to point to the fact that normal organisms of the fæces passing through the intestinal canal of this fish acquire an *increased* '*toxic influence on the thyroid gland* In the author s experiments on rats he states that ingestion of fæcal material from even non goitrous subjects will produce goitre, which rather militates against his experiments, proving that there is a specific goitrigenous infective organism Major McCarrison has shown that in mountain villages where one is situated above another there is a correlation between the increase of fæcal contamination of the water-supply and the prevalence of goitre Might it not be worth while to make plate cultures and counts of the different fæcal organisms in the water supply of a series of such villages ? It would also be of interest to ascertain whether there was any modification, morphological or cultural, in the organisms found in the water supply to the villages where goitre is most prevalent

It is interesting to note that the author does not consider that Graves's disease is the direct outcome of the flooding of the organism with thyroid substance, as it is stated to be by Biedl According to Major McCarrison it is not the escape of excess of the thyroid secretion which is at fault, but a bacterial toxin which stimulates the gland to increased activity The remedy, therefore is to seek the source of the bacterial toxin and eliminate it He enters a protest against the tendency of some surgeons to operate in all early cases as a routine procedure

We can cordially commend this valuable work, so rich in original thought and observation Naturally all the links of the chain of evidence upon which our present knowledge of thyroid-parathyroid disease is founded are not of equal strength and probable durability Some of the links contributed by the author will require strengthening by further investigation and by confirmation of independent observers

The book is interesting in style and lucid in exposition, is well printed and illustrated We congratulate the author on having made a noteworthy contribution to British medicine

LIBRARY TABLE

Daily Drill for the Voice By ROSE I PATRY Published by the author at 3 Lower Seymour street Portman square, London W —In this pamphlet on voice management Miss Patry has done a sound and useful piece of work. The want of skilled attention for sufferers from shell shock has been keenly felt by those coming in contact with them There is not only the need for medical help but for help from persons skilled in voice production and voice correction There are difficulties in the way of supplying the latter kind of assistance to many of the victims who require it most and the possibility of helping themselves, as indicated in "Daily Drill for the Voice ' will be most useful information The book contains six groups of exercises for control of breath, voice and body graded with obvious precision Exercises in regular control of the breath and in use of the voice are combined with movements of the arms ribs chest and with such ordinary movements as writing walking rising from a seat so that the recovered or corrected voice is from the first placed in the circumstances of experiments upon rabbits—namely that after immunisation with dead *B coli*, the subsequent injection of killed emulsions of *Staphylococcus aureus*, the bacillus of Friedländer, or a streptococcus increases the production of the specific primary agglutinins, so long as the animal retains any measurable degree of acquired immunity[5] Perhaps the figures may be interpreted so as to carry the matter a little further and to suggest that inoculations with allied, or group, organisms point to the probability that typhoid and paratyphoid bacilli differ so much in their essential metabolism as to classify them individually as heterologous organisms The results of our previous absorption experiments and their inferences as to the absence of co-agglutinins in sera containing mixed antibodies lend support to the surmise[1]

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

A CASE OF VINCENT'S INFECTION INVOLVING MOUTH, EYES, AND PENIS

BY F B BOWMAN, M B TOR,
MAJOR C A.M.C O C NO 2 CANADIAN MOBILE LABORATORY

SINCE publishing a preliminary report on "Infectious Stomatitis among Troops" in 1916[1] many cases of this serious condition have been seen That cited here would seem to be of sufficient interest to warrant an individual report

Case history—Captain ——, aged 30 Always had good health until the present illness occurred About March 1st, 1917, he noticed that he began to lose his voice He does not describe any pain in connexion with this, but it seemed to be due to a sense of constriction in the throat The glands in the neck were not tender The condition gradually became worse, and on March 15th, when instructing a party in trench work at night, he had a severe chill and a cough developed He then noticed soreness of the eyes with watering and had great tenderness of the gums On March 19th he was admitted to hospital

Examination on admission—Temperature 102° F Greatly depressed, feels chilly, and can eat nothing but fluids because of the soreness of the lips and inside of the mouth He was seen by me on March 21st Examination showed a very severe conjunctivitis, with a large amount of thin discharge present containing flakes of whitish material, the conjunctivæ were red, a certain amount of photophobia present The mouth was half opened and the lips covered with angry herpetic looking ulcers, some of which were covered with a fragile whitish membrane These seemed to be confined to the lips, and had not extended to the surrounding skin On account of the pain it was impossible to open the mouth, and it was very difficult to retract the lips The gums were reddened, the teeth bathed in pus and pressure on the gums caused severe bleeding The hard palate was covered by a whitish membrane, which came away easily, leaving a bleeding surface The throat, which could be seen only partially, was covered with a membrane also but there was no evidence of any deep ulceration Smears were made from the eyes and from the ulcerated areas in the mouth, as well as from the gums These showed large numbers of Vincent's organisms (*spirochætæ and fusiform bacilli*)

A mixture of arsenic and ipecac, as recommended in a previous paper, was used three times daily as an application to the gums and lips, and also as a mouth wash Boracic compresses were advised for the eyes In 24 hours the mouth felt "easier," although it was impossible to open the lips After three days from the time that I had first examined him the patient confided in me that he had a peculiar sore on the penis and this on examination was found to be a small red ulcer with a membrane over it surrounding the meatus Smears showed Vincent's organisms present in large numbers For treatment the same solution as that used in the mouth was applied on a small pad of cotton wool, and changed three or four times a day The ulcerated area was completely healed within a week The Wassermann reaction was negative on two occasions During the second week after admission the patient developed a severe pleuritis, with a fairly large amount of fluid present, but this apparently was simply coincident, and had no relation to the other conditions described here, although the chill and cough, which developed early in the disease, were the first signs of pleuritis

When last seen by me the mouth, eyes, and penis were entirely healed, and the marked depression which was present at first had disappeared This was one month after his admission to the hospital

Summary—The case reported here is particularly interesting from the fact that three separate and distinct areas covered by mucous membrane were infected by Vincent's organisms The primary infection was probably in the mouth and had been transferred to the glans penis and conjunctivæ by means of the fingers Treatment with the following prescription as a mouth wash with directions that the mixture should not be swallowed, quickly cleared up the condition —

℞ Vin ipecacuanhæ ℥ ss
Glycerini ʒ j
Liq arsenicalis ad ℥ j

ANOTHER CASE OF MALARIA CONTRACTED IN ENGLAND

BY R LOY WILCOX, M.R C S, L R C P LOND,
SENIOR ASSISTANT MEDICAL OFFICER PARK HOSPITAL, LEWISHAM S.E

G T, aged 20 years, had an abdominal operation at Salonica for wounds received in action on Nov 28th, 1916, but has been in this country for over three months He was admitted to the Park Hospital certified to be suffering from scarlet fever on July 27th, with the history of vomiting and sore throat on the previous day

On admission he had a faint punctate erythema, the tongue was heavily furred, and the fauces were swollen and injected The temperature was 104°F, but there was no rigor The temperature continued irregular and at midnight July 30th–31st was 104°, but again there was no rigor It was normal on the morning of July 31st and remained normal until 7 15 P M on August 1st when the first rigor occurred, the temperature rising to 104° By midnight it was normal again A careful examination of heart and lungs revealed nothing abnormal

On August 3rd, at 2 30 P M, he awoke from his sleep and asked for a hot drink as he thought an attack was coming on A rigor followed immediately, and then malaria was thought to be the cause of the trouble, and the man, who had previously been taking sodium salicylate, was put on quinine sulphate 3 gr every four hours Another rigor occurred on the 5th, and the dose of quinine was increased to 6 gr every four hours Afterwards there were no more rigors and the man rapidly became convalescent On the 9th the dose of quinine was reduced to 3 gr every four hours, and on the 13th it was omitted altogether A blood film taken during the height of an attack was kindly examined by the pathologist of the military hospital from which the man came and he reported that the tertian parasite was present.

The rash present on admission disappeared in a day or two and as neither the tongue showed any trace of peeling at any time nor was any desquamation seen the diagnosis of scarlet fever was abandoned and the man discharged well on August 21st

I am indebted to Dr T F Ricketts, medical superintendent, for permission to publish this case

THE Local Government Board has approved of the appointment by the Bournemouth town council of Mr William Bertram Lawrence as tuberculosis officer for the period of the war subject to his services not being further required by the War Office

MEMORIAL BED TO THE LATE MR JOHN PLATTS—As a memorial to the late Mr John Platts his sister and legatee, Mrs M A Shipley has endowed a bed in the wards of the Leicester Royal Infirmary Mr Platts was a well known representative of the firm of Messrs Southall Brothers and Barclay, manufacturing chemists Birmingham and for many years was closely associated with medical work in the neighbourhood of the hospital This fact is recorded on a memorial plate over the bed

Reviews and Notices of Books.

The Thyroid Gland in Health and Disease By ROBERT McCARRISON M D R.U I D Sc. Belf. F R.C P Lond., Major Indian Medical Service, Lauréat de l Académie de Médecine, Paris With numerous illustrations London Baillière, Tindall and Cox. 1917 Pp 286 Price 12s 6d net.

FROM the time of Hippocrates and Aristotle onwards impure drinking water has been held by the majority of physicians to be the cause of goitre. But it is only within comparatively recent years that we have approached a precise knowledge of the ultimate causes of disease of the thyroid parathyroid glands by the correlation of facts and inferences based upon the results of experiments upon animals, clinico-anatomical observations upon man, and epidemiological investigations It is a great satisfaction to recall the fact that many British physicians and physiologists have acted as pioneers in important contributions to our knowledge of the thyroid gland in health and disease, and we welcome this latest valuable pioneer work of Major McCarrison which sets forth in a lucid, comprehensive and interesting manner a subject which he has studied experimentally epidemiologically, and by clinico-anatomical observations for the past 14 years During this time he has contributed numerous original papers to medical journals and societies including the Proceedings of the Royal Society, bearing upon goitre and allied subjects Major McCarrison speaks authoritatively as a physician of experience, and throughout all three parts into which the work is divided there is exhibited a most extensive knowledge of the literature

The first section deals with the thyroid and parathyroid glands in health, the second with the factors which cause them to depart from health, and the third with the morbid states of goitre and cretinism tetany myxœdema, and exophthalmic goitre In the appendix there are two series of cases showing the effects of intestinal antiseptics on goitre as well as a brief summary of the author s more noteworthy epidemiological and experimental observations

In reviewing this important contribution to medical literature we shall best serve the interest of the profession by briefly referring to Major McCarrison s conclusions regarding the causation prevention and treatment of endemic goitre a subject of great importance seeing that in India at the present time there are not less than five million persons afflicted with goitre while half a million is a low estimate of the number who suffer from its congenital manifestations It was generally believed that permanent hardness of the water was the cause of goitre—e.g Derbyshire neck was attributed to this, while not denying that it may be to some extent a contributory factor Major McCarrison s observations show that it is not an essential cause Within recent years the many theories as to the causation of endemic goitre have been reduced to the following (1) Chemical ingredients of drinking water, (2) geological peculiarities of the soil imparting to the soil a specific colloidal poison, (3) faulty nutrition (4) living micro-organisms The author claims that his experimental and epidemiological observations prove that living organisms are the essential cause of the disease and he puts forward the following premises as proof that fæcal contamination of the water-supply by a living and specific micro-organism is the cause of goitre 1 In villages where goitre prevails this disease shows a steady increase in proportion to those conditions which increase the impurity of the water by fæcal contamination 2 He claims to have produced goitre experimentally in man by ingestion of the residue left on the candle of a Berkefeld filter after filtration of goitrigenous water This residue when boiled does not cause goitre 3 The administration of beta-naphthol and thymol and other intestinal antiseptics may cause the disappearance of the goitre in young subjects 4 The researches on trout by Marine Lenhart and Gaylard demonstrate that fish confined in tanks one above the other on a single water-supply exhibit an increasing thyroid hyperplasia in descending from above down 5 He claims to have produced goitre in rats and goats by feeding them on fæcal material from goitrous and even non-goitrous subjects, also from cultures, aerobic and anaerobic. The anaerobic are the more potent 6 Congenital goitre with cretinism and parathyroid disease can be produced experimentally by feeding the mothers throughout pregnancy with these cultures Photographs of men and animals and photomicrographs of sections of the glands are given Finally, Major McCarrison claims that vaccines prepared from intestinal organisms are capable of causing the disappearance of recent cases of goitre when injected in appropriate doses at weekly intervals We are of opinion, however, that further observations will have to be made before the value of autogenous vaccines in the treatment of goitre can be accepted as proven With regard to the infective organism, Major McCarrison claims that it lives in the soil of infected localities, and particularly in soil which contains a high proportion of organic matter of human or animal origin. It seems that " the great source of the disease is the infected individual, and that he is the producer, the reservoir, and the distributor or carrier of the infecting agents " The author, therefore, implies that there is a specific organism capable of producing goitre, which exists in man living in districts where goitre is endemic This organism has not been isolated and obtained in pure culture, in fact, the observations on trout would seem to point to the fact that normal organisms of the fæces passing through the intestinal canal of this fish acquire an increased toxic influence on the thyroid gland In the author s experiments on rats he states that ingestion of fæcal material from even non goitrous subjects will produce goitre, which rather militates against his experiments, proving that there is a specific goitrigenous infective organism Major McCarrison has shown that in mountain villages where one is situated above another there is a correlation between the increase of fæcal contamination of the water-supply and the prevalence of goitre Might it not be worth while to make plate cultures and counts of the different fæcal organisms in the water supply of a series of such villages? It would also be of interest to ascertain whether there was any modification, morphological or cultural, in the organisms found in the water-supply to the villages where goitre is most prevalent

It is interesting to note that the author does not consider that Graves s disease is the direct outcome of the flooding of the organism with thyroid substance, as it is stated to be by Biedl. According to Major McCarrison it is not the escape of excess of the thyroid secretion which is at fault, but a bacterial toxin which stimulates the gland to increased activity The remedy therefore, is to seek the source of the bacterial toxin and eliminate it He enters a protest against the tendency of some surgeons to operate in all early cases as a routine procedure

We can cordially commend this valuable work, so rich in original thought and observation Naturally all the links of the chain of evidence upon which our present knowledge of thyroid parathyroid disease is founded are not of equal strength and probable durability Some of the links contributed by the author will require strengthening by further investigation and by confirmation of independent observers

The book is interesting in style and lucid in exposition, is well printed and illustrated We congratulate the author on having made a noteworthy contribution to British medicine

LIBRARY TABLE

Daily Drill for the Voice By ROSE I PATRY Published by the author at 3 Lower Seymour street Portman square, London W —In this pamphlet on voice management Miss Patry has done a sound and useful piece of work The want of skilled attention for sufferers from shell shock has been keenly felt by those coming in contact with them There is not only the need for medical help but for help from persons skilled in voice production and voice-correction There are difficulties in the way of supplying the latter kind of assistance to many of the victims who require it most and the possibility of helping themselves as indicated in Daily Drill for the Voice will be most useful information The book contains six groups of exercises for control of breath voice and body graded with obvious pre ercises in regular control of the breath and oice are combined with movements of t ct and with such ordinary movement ng rising from a sea so that the voice is from the first placed i daily life Care, too, has been given to the amount of mental effort required in performing the exercises, the early ones being more mechanical than the late ones One point that might offer some difficulty to the inexperienced reader is the exact meaning of "the initial sound" of a consonant A list of the phonetic sounds as used in the pamphlet might with advantage have been added to the introductory directions and so have removed any doubt on the part of the learner Thus we should have had explained such an exercise as "Make the shape of the mouth of the following consonants W, W, W " To the uninitiated what is the shape of the mouth for "W"? The pamphlet contains no exercises dealing with such sounds as "th," "sh," "ch," "j," or difficult combinations, e g, "pl," "gr," "st," "sk," which leads us to suggest that Miss Patry should produce a sequel in the shape of a series of exercises of a higher standard of difficulty Meanwhile any soldier or sailor whose speech is affected may derive invaluable benefit by using "Daily Drill for the Voice"

A Farmer in Serbia By ELLEN CHIVERS DAVIES London Methuen and Co 1917 Pp 248 Price 6*s* net — This is a very readable book, composed to some extent of articles which have been contributed to the *Manchester Guardian*, the *Morning Post*, and the *Yorkshire Post* enlarged into a diary, bearing dates from the first summer of the war until the time when Bulgarian defection led to the over running of Serbia by the enemy The book tells an interesting and pathetic story simply but quite poetically It is easy to realise the beauty of the scenes in which many of the struggles were enacted, as well as to comprehend what a horrible tragedy it was that the Allies were unable to make good the Serbian resistance The proceeds of the sale of the book will be given to the Serbian Relief Fund

Health Survey of New Haven Yale University Press New Haven Connecticut 1917 Pp 144 Price 75 cents net —This Survey was prepared at the request of the Civic Federation of New Haven and is now published in pamphlet form by Yale University, the cost being defrayed from the Anna M R Lauder Memorial Foundation in the Yale School of Medicine The record of an exhaustive sanitary survey is extremely practical, and each description of existing positions is followed by a definite recommendation where a method of reform has suggested itself to the authors The one essential need made clear by their investigations is that of providing the health department of the city with six efficient and well-qualified divisional directors, who could supervise the work of their subordinates and aid the health officer in the organisation and development of particular lines of energy The expansions of the work of the department of health which appear cardinally essential to the authors include the re arrangement of the work of the Board of Health, the strengthening of the various staffs with a more reasonable division of their labours, the reorganisation of school inspection with the provision of school clinics, and the appointment of an expert on tuberculosis to develop a campaign against the disease The cost of the suggested additions are estimated at about £7000 a year, an increase of per capita expenditure for health work in the city from 26 to 48 cents annually This strikes us as being a remarkably moderate figure The public health authorities of English cities having a comparable population of something between 100,000 and 150 000 might with advantage study this well arranged pamphlet All the modern problems of preventive medicine receive notice, and in many places there are indications for reform which would be as applicable in a British as in an American city

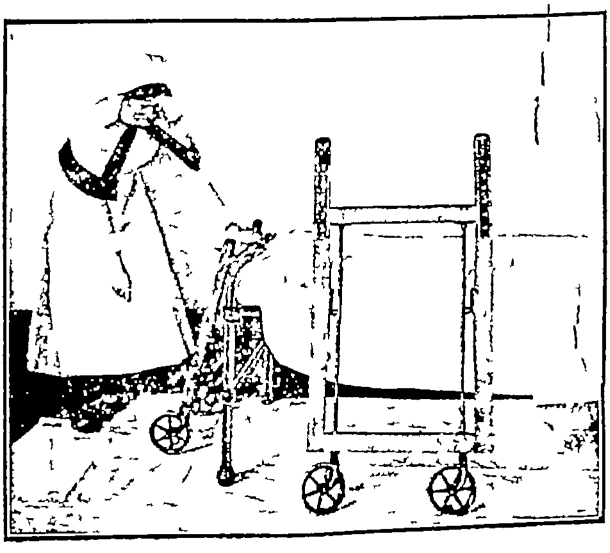
Manual of Chemistry By W SIMON, Ph D, M D and DANIEL BASE, Ph D Eleventh edition thoroughly revised London Baillière Tindall, and Cox. 1917 Pp xvi + 648 Price 18*s* net —In the preparation of this edition the chief change made has been the omission of the chapters on light and electricity of the previous editions, though the articles on the spectroscope and the polariscope have been retained, since their applications in analytical work are indispensable This course has made room for much new matter, particularly in the first subdivision of Section II dealing with the non metals In this section some space is given to an account of reversible reactions and chemical equilibrium In previous notices of this book we have always expressed an appreciation of its clearness of statement, its logical sequence of facts, its remarkable coloured illustrations of tests and its general soundness on both theoretical and practical questions The student in the laboratory will find this book of considerable service, even though he be a beginner

A Laboratory Manual of Organic Chemistry for Medical Students By MATHEW STEEL, Ph D New York John Wiley and Sons, Inc London Chapman and Hall, Limited 1916 Price 6*s* net Pp 193 —A useful series of tests is here given for more or less familiar organic substances, setting forth their properties as well as those reactions which serve for their detection Particular attention has been given to the selection of experiments which are of special interest to medical students The sections on alkaloids proteins, amines and amides are the best examples of this plan In the directions given in making the tests the use of definite quantities of reagents is enjoined, which has the double advantage of obviating waste of material, and of securing a satisfactory response to the test The book presents a sound practical course of laboratory teaching confined to organic substances

New Inventions.

THE "TOWNSEND LOCK" BED LIFT AND TRANSPORTER.

RECENTLY we noticed two devices for moving the sick and their beds We here describe a bed lift and transporter which is the invention of two members of the Inquiry Bureau of the 2nd Southern General and Beaufort War Hospitals, Bristol, and their Auxiliaries The apparatus is simple light, strong, and effective and affords a ready means of wheeling a patient in bed, without any jarring or discomfort, into the open air, even over grass or uneven ground As will be seen from the illustration, the invention consists of two square frames (one for the head and one for the foot of the bed) running on swivelled rubber tyred wheels. The frames are hooked under the top bar of the bed which is levered up by pushing forward the bottom of the frame The frame is then clamped securely in position by hooks sliding on its face No lifting is required, the leverage being equal to any normal load on the bed and the adjustments can be made in about 15 seconds The apparatus is adjustable, and can be fitted to almost any ordinary hospital bed



Any proceeds resulting from the commercial use of this invention, which is priced at £4 10*s*, will be devoted to the funds of the Inquiry Bureau Only one set of frames is required for any number of beds

Further details may be obtained from the Honorary Secretary, Inquiry Bureau 39, Broad street, Bristol

At The Front–

Since the beginning of the war tens of thousands of packages of

Antiphlogistine

have been used in the Hospitals of France alone

Physicians and surgeons in His Majesty's service on duty in France should bear in mind that Antiphlogistine obtained from our Paris Laboratory, No 116 Rue de la Convention, is composed of the same C P ingredients and compounded according to the same formula as the British Antiphlogistine, made at No 41 St Ann's Road, Bow, London, E 3

Recurrent Fever
SYPHILIS

GALYL

Frambœsia
Sleeping Sickness

GALYL is as effective as SALVARSAN or NEOSALVARSAN on Spirochætes and Trypanosomes, more rapid in action, and free from the neurotropic and congestive action of these preparations

FOR INTRAVENOUS INJECTIONS — (Fig 1)

(1) DILUTE.—GALYL is supplied in neutral glass ampoules containing the necessary dose of Sodium Carbonate sterile distilled water only being used for the dissolution.

(2) CONCENTRATED —A special outfit containing one dose GALYL, one ampoule sterilised solution and one small filter is supplied

DOSES.
0 20—0 25—0 30—0·35—0 40

(3) FOR INTRAMUSCULAR INJECTIONS — (Fig 2)

GALYL is supplied in GLUCOSE SOLUTION

DOSES
0 10—0 15—0·20—0 30.

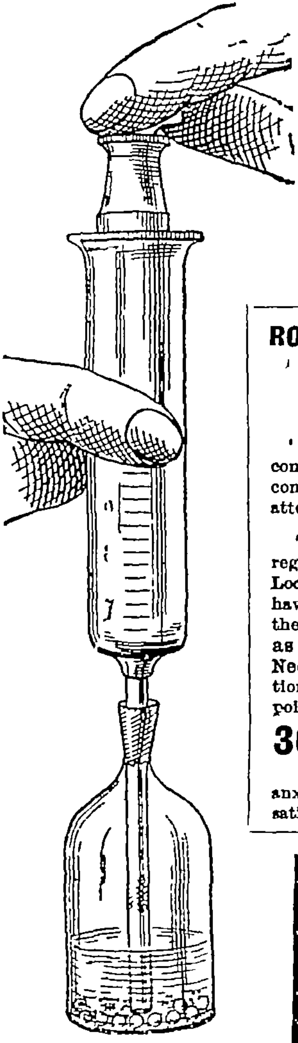

Fig 1.

ROYAL COMMISSION ON VENEREAL DISEASES.

Final Report of the Commissioners

SUBSTITUTES FOR SALVARSAN

" another French substitute **GALYL**, a compound of arsenic and phosphorus has recently come into prominence and its use has been attended with considerable success

' Favourable reports have also been obtained regarding the preparation **GALYL**. At the Male Lock Hospital 1000 injections of this substance have been administered and it is reported that they have been attended with as good results as in the cases treated by Salvarsan and Neosalvarsan in no instance were the injections followed by reactions indicative of arsenic poisoning "

3000 injections (intravenous) were given in one of our Service Hospitals

No case has given the slightest cause for anxiety and the clinical results are very satisfactory *Staff Surgeon's Report*

THE NEW INTRAMUSCULAR GALYL

The GALYL is in the form of a Sodium Salt in a weak solution of glucose. This is much easier to use and more rapidly absorbed than the oily emulsion It is in every way identical with the intravenous—efficacy, dose, price &c, only differing in administration

' The results are excellent both immediate in the clearing up of evident lesions and ultimate, as proved by the Wassermann test. Personally I have used this preparation in over 400 injections with the best results and without the slightest mishap or inconvenience to the patient

Yours faithfully, Dr —— "

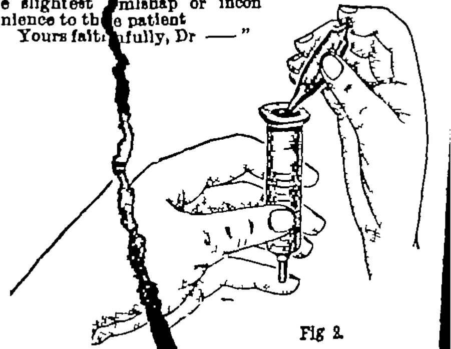

Fig 2.

The technique is simple

Fig 2 shows the ampoule of Galyl being emptied into the syringe barrel—the needle is now fixed on the neck of the syringe and the plunger inserted into the barrel. The injection is then ready for administration.

HECTARGYRE

(Mercurial Salt of Hectine)

ARSENIO-MERCURIAL TREATMENT

Hectine is a soluble Arsenical derivative with an extremely low toxicity and combined with mercury is well tolerated even where prolonged treatment is necessary such as severe cases of intractable Syphilis, in which it has yielded highly

The Treatment of Wounds in War

Professor W W KEEN has not been at the front, but in his eightieth year he is a surgeon of large experience and breadth of view, and his report[1] on the treatment of war wounds, compiled at the request of the National Research Council of America, will be studied with profit by many whose daily work brings them in contact with the wounds of war and with the controversies thereon arising The Atlantic, while reducing magnification, may at the same time improve perspective After three years of fighting the number of different methods of treating wounds is still so great as to prove that there can be no one preferable technique, and this would be expected when we remember the diversity of circumstances and environment in which the injuries are inflicted. General principles may evolve, though a one and only procedure need not be expected But many of the new remedies brought forward during the war have been acclaimed by their inventors as almost a panacea for all sorts and conditions of wounds, and that there is no small amount of truth in many of the claims that are made proves simply that in dealing with an enormous mass of wounded material large groups having similar manifestations have been found. Various new conditions have been met with, and the new lines of treatment have been devised for the most part to deal with these new conditions The sepsis seen in many of the wounds in the present war is of a virulence rarely if ever encountered in civil practice and almost unknown in previous campaigns Gas gangrene and tetanus were rife in the early months of the war The long interval between the infliction of the injury and even the first dressing, which in some sections of the line was bound to occur, led only too often to the penetration of microbes deeply into the wounds, and when close trench war prevailed everywhere great difficulties were experienced in bringing in the wounded But now that the movement on the western front, which we are considering to day, is towards the east always, so that the ground over which the advance is being made remains in our hands, the wounded receive aid much earlier than was formerly the case, and some of the older problems have disappeared

The skill and inventiveness of the army surgeons, their civil colleagues, and the pathologists have been exercised to the utmost, and the results of treatment have steadily improved Tetanus has almost disappeared every wounded man receives one or more doses of antitetanic serum as a matter of routine, and the effect is intensely striking to all workers in military hospitals The treatment of gas gangrene presented what our American allies would term 'a tough proposition Various methods were proposed and tried, but until recently—sad to think'—the safest treatment too often was to perform a flapless amputation, so that the perfect drainage and the exposure of the anaerobic organism to the air led to its elimination. Now the claim has been made for a new serum that it will deal as effectively with gas gangene as the tetanus antitoxin deals with tetanus If this claim should prove well founded, a valuable addition will have been made to our armamentarium, and we hope that further work in this direction may clear up all the doubts For the treatment of wounds infected with the ordinary pyogenic organisms many procedures have been devised One of the most valuable methods of lessening the sepsis, and one which often permits of healing by first intention, is excision of the wound so that a large proportion of the entrant micro organisms is mechanically removed, while the tissues damaged by the toxins are taken away and clean healthy tissues are brought together Even though a true union by first intention may not always be obtained, yet the suppurative process is immensely weakened, and healing is promoted The whole work of Sir ALMROTH WRIGHT in these directions has tended towards simplification and towards a scientific comprehension of the underlying pathology of the conditions met with For the treatment of wounds which have already become infected, but cannot from their extent be excised, Sir ALMROTH WRIGHT'S researches have been invaluable, while two methods have emerged to which the authors names have been properly attached CARREL'S method of using DAKIN'S hypochlorite solution, and RUTHERFORD MORISON'S employment of "B I.P.P," although differing widely in the means employed, are both undoubtedly effective in preventing and reducing sepsis in wounds, and each has proved useful in promoting their healing By the Carrel method it is claimed that in nearly all cases of wounds in which the infection has not progressed too far it is possible by the regular instillation of the hypochlorite solution to render the wound germ free within a week or two, and the asepsis is guaranteed by a bacteriological test, and when this aseptic stage is reached the wound may be sutured and it will heal without suppuration The Carrel method is the only one described in detail by Professor KEEN, as, judging by published statements, he finds the results superior to those of any other method The work of Dr A DEPAGE on compound fractures at La Panne has specially impressed him The "B I P.P' treatment consists in filling the wound with a paste of bismuth subnitrate, iodoform, and paraffin, and when it is closed with sutures in many cases the wound heals rapidly with a minimum of suppuration

In the present issue of THE LANCET appears a paper by Major JAMES PHILLIPS R A M C, who has worked at the Bradford War Hospital, and from a study of the various forms of treatment he has evolved the "Bradford method with which he has

attack but rather has made the circumstances more tolerable, and it is this growing bravery which has become a feature of our psychology, and which accounts for the fact that a short relief from strain is almost invariably followed by a complete recovery of balance.

◆

Training in Citizenship.

THE prophylaxis of responsibility has never been a success in this country, and the adolescent boy or girl exposed to the full brunt of independence without any previous experience often succumbs to attacks of wrongheadedness, with results which may in one social class lead only to distressful family relations and in another to collision with external authority. The recent outbreak of juvenile crime is an example of the latter which cannot be set aside as a matter solely for punitive action. The Bishop of BIRMINGHAM in a recent letter to the *Times* describes with accuracy and restraint the nature of the complaint and goes on to put his finger upon its cause. Reasonable obedience to authority and regard for the demands of the social necessities of the community are, he says, almost dead in the vast mass of the youth of the land, as a natural and inevitable consequence of the fact that the growing girl and boy receive little assistance in any direction towards a training in citizenship. This has been the prime failure in the national education of the present time, and the result is just as inevitable as the exposure to measles of a community which has had no training in protection against it. Dr. WAKEFIELD considers—and all thoughtful people will agree with him—that an effective training in citizenship is an essential part of elementary education. But it is no use now relying upon a future educational system which will come too late to be effective for the upgrowing generation, even if it accomplishes something useful later on. He therefore suggests a combination of existing organisations dealing with young people for the purpose of conference and combined action. The response already made to his letter shows that some at all events of these organisations are keenly alive to the need of action, which is indeed imperative for the satisfactory solution of the myriads of after war problems.

THE Harveian Oration of the Royal College of Physicians of London will be delivered at the College by Dr. Robert Saundby, at 4 o'clock, on Thursday, Oct. 18th.

LITERARY INTELLIGENCE.—Lord Rhondda will contribute an introduction to the new edition of Sir William Crookes's book on "The Wheat Problem," which Messrs. Longmans will shortly publish. An additional chapter on Future Wheat Supplies has been contributed to the book by Sir R. Henry Rew, K.C.B.

WAR EMERGENCY FUND OF THE ROYAL MEDICAL BENEVOLENT FUND.—At a meeting held in London on July 31st last it was decided to hold a general meeting of the medical profession in October in order to nominate a representative general committee and to discuss the best methods of promoting this appeal. This meeting has now been arranged for Wednesday, Oct. 10th, at the Medical Society's, 11, Chandos-street, Cavendish-square, W., at 5 P.M. It is hoped that the meeting will be largely attended in order that the appeal may be well supported and made widely known to the medical profession and the public. Lieutenant-Colonel Sir Alfred Pearce Gould, K.C.V.O., will preside.

INSINCERITY IN CASES OF WAR INJURY.

A RECENT number of the *Paris Médical* contains an essay on insincerity as a feature of certain cases among the wounded which, though its conclusions are admittedly tentative, forms an interesting attempt to clear the air and facilitate further investigation. The authors, M. Laignel-Lavastine and M. Paul Courbon, are in charge of the centre, under the military government of Paris, for the examination of soldiers who, in the absence of evidence of organic disease, are suspected of "ill will." They divide functional states into two groups. In the first the patient is unaware that he is the originator of the troubles of which he complains, and is therefore sincere in making himself out to be ill; here are placed those psychoses characterised by impairment of the critical faculties, notably hysteria. In the second group the abnormal functional manifestations are directly dependent on the conscious "mauvaise volonté" of the patient; to be consciously aware of being the cause of his own complaint is the mark of the simulator. In the latter case the physician, recognising the illegitimate nature of the symptoms complained of, may distinguish three categories: (1) somatic disturbances, comprising mutilation and "pathomimia," or the artificial concoction of a diseased condition; (2) functional disturbances or simulation properly so called; (3) functional disturbances grafted on a genuine organic affection, including exaggeration and perseveration. The diagnosis of malingering is really a psychological problem; in other words, the question is whether the patient has or has not the intention of deceiving. Now to detect an individual's intention is notoriously difficult; it is perhaps more prudent, therefore, merely to say, in a particular case, that there is no reason why the symptoms should not disappear. But this attitude is obviously unsatisfactory when dealing with such cases as M. Laignel-Lavastine and M. Courbon have under their care; their task is to search the reins and the hearts and to face the risk of making mistakes. If to ourselves our inner man is the sport of involuntary or unconscious deceits which render an exact determination of our motives all but impossible, how can we hope to settle analogous questions in others? The answer is that precisely this intimate deception does not impose or has less power of imposing on the outside observer. Experience shows there are constitutional peculiarities in different individuals which determine the variations in their intention to deceive. There is the pure simulator or malingerer without apparent excuse, who does not wish to risk his life or to undergo the fatigues of warfare. Among the numerous types who advance some excuse may be distinguished the emotional simulator, who thinks he could never bear the sights of the battle-field; the hypochondriac, who thinks his physique would not stand campaigning; the man who pretends he would be more useful in less exposed positions or declares he has already "done his bit," or excuses himself by instancing the good fortune of some comrade. Often, too, the patient begins to malinger at the instigation of his family or continues to do so to prove to the physician he has obtained excellent results It is essentially a combination of these two methods, the Rutherford Morison and the Carrel treatment, preference being given to the one or the other according to the lesion, and sometimes the two are employed in turn Success depends not only on the actual method itself, but also on the application, and this is why the inventor of a new method may obtain results superior to those of others If a surgeon is working on lines in which he does not believe, it is unlikely that he will meet with success, he does not carry out instructions with the care and thoroughness that he would use if he believed absolutely Little details vital to success will be omitted or imperfectly carried out, and the method will be dismissed as of little or no value At the first introduction of antiseptic surgery surgeons who did not believe in it condemned it as useless, "for," said they, "we have used carbolic acid in the wound and pus was formed as usual," forgetting or ignoring that the principle of antiseptic surgery is not merely the employment of carbolic acid There is no finality in surgery, and we certainly have not reached any finality in the treatment of wounds in war, but it is certain that in the past three years we have learned much of the treatment of these wounds, we have been able to save life and to prevent much pain and delayed healing

Air-Raid Psychology and Air-Raid Perils

In certain schools of biological thought, as we had occasion to point out when discussing the subject of air raid psychology a few weeks ago, a favourite theme is the adaptation of the organism to repeated sense stimuli of a given type, whereby appropriate reflex action by way of defence or otherwise is installed Now the aerial bombardment of crowded cities is a recent development of "civilised" warfare, our sense organs have not in any general manner become adapted to the stimuli, with the result that, among the population taken in mass, definite defensive behaviour has not been evolved as a normal course But although it would be too much to expect that in so short an experience of aerial bombardment the public conduct should have devised at once the wisest courses of action in circumstances which are not only very trying in themselves but very diverse in their dangers, yet it may be claimed that in London and its environs the inhabitants have already gone a long way towards behaving in bulk with bravery and prudence It is a truism that a crowd is impulsive and mobile, but their common impulse and consequent movement, when properly directed, spread rapidly, grow wiser and stronger as they spread, and tend to shape the behaviour of the unstable members with a force that is augmented by geometrical progression London behaved well at the beginning in face of the new perils, and the beginning is being justified by the sequel

London during last week endured five aerial raids of varying severity, and each of those raids had as furious an intent as any of the others During this week, as we write, London has been the objective during two nights of similar exhibitions of frightfulness, and there is not a doubt that the immense populations involved have learned with speed and uniformity lessons which have saved many lives, which will save more lives, and which—this is of infinite importance—have enabled them to analyse their dangers, estimate the severity of those dangers, and front them therefore with that spirit of comprehension which is the basis of fortitude The experiences of London happen to be our text, but they exemplify, of course, the experiences of all centres of aerial attack At the present moment London is to the enemy the symbol of our national might and its inflexible resolves, and is, therefore, the object of their most determined onslaughts, but lessons learnt from events in London are applicable throughout the zone of war The people of London, including those of the densely populated rings without London proper, now appreciate that their risks can be divided into two—namely, those from the bombs of the enemy and those from the defensive gun fire, and they know, further, that by as much as the hideous din and luridly magnificent atmospheric effects constitute the most terrifying stimuli to their senses, by so much is fear misplaced, because it is the work of our defensive machinery, as the enemy in vain tries to penetrate, which accounts for nearly all which they can hear or see The Home Office has drawn up a leaflet containing a summary of the advice which has been given so far to the public, with the additions and modifications which events appear to justify An intelligent reading of this leaflet proves how small are the risks to which the bulk of the population is submitted from the supreme danger of being bombed by the enemy, but how great are the chances of catastrophe from the avoidable risks accompanying our own defensive activity, while it is this activity which rings us round for long periods and on repeated occasions with the tumult of hell Almost all of what we hear and what we see—and the less we try to see anything the better—amount to sound and fury, and although they are far from signifying nothing, the simple precaution of taking cover leads to probable safety

The evidence of medical men who reside in the attacked centres or who have been present quickly on the scene of an accident, or who have been summoned to attend the victims of shock, all goes to show that the inhabitants of London have steadily improved in courage and calm as they have learnt the measure and the sources of the dangers to which they are subjected, and we are glad to state positively that among those whose natural anxiety has been greatest—and there is not a soul among us who does not feel anxious during an aerial attack for himself as well as for those nearest and dearest to him—the power of recuperation has manifested itself with great rapidity The recurrence of the dangers has tended not to exaggerate those dangers, as the enemy hoped fondly would happen if attack followed often upon attack but rather has made the circumstances more tolerable and it is this growing bravery which has become a feature of our psychology, and which accounts for the fact that a short relief from strain is almost invariably followed by a complete recovery of balance

Training in Citizenship

THE prophylaxis of responsibility has never been a success in this country and the adolescent boy or girl exposed to the full brunt of independence without any previous experience often succumbs to attacks of wrongheadedness, with results which may in one social class lead only to distressful family relations and in another to collision with external authority The recent outbreak of juvenile crime is an example of the latter which cannot be set aside as a matter solely for punitive action The Bishop of BIRMINGHAM in a recent letter to the *Times* describes with accuracy and restraint the nature of the complaint and goes on to put his finger upon its cause Reasonable obedience to authority and regard for the demands of the social necessities of the community are, he says, almost dead in the vast mass of the youth of the land, as a natural and inevitable consequence of the fact that the growing girl and boy receive little assistance in any direction towards a training in citizenship This has been the prime failure in the national education of the present time, and the result is just as inevitable as the exposure to measles of a community which has had no training in protection against it Dr WAKEFIELD considers —and all thoughtful people will agree with him—that an effective training in citizenship is an essential part of elementary education But it is no use now relying upon a future educational system which will come too late to be effective for the upgrowing generation, even if it accomplishes something useful later on He therefore suggests a combination of existing organisations dealing with young people for the purpose of conference and combined action The response already made to his letter shows that some at all events of these organisations are keenly alive to the need of action, which is indeed imperative for the satisfactory solution of the myriads of after war problems

INSINCERITY IN CASES OF WAR INJURY

A RECENT number of the *Paris Médical* contains an essay on insincerity as a feature of certain cases among the wounded which, though its conclusions are admittedly tentative forms an interesting attempt to clear the air and facilitate further investigation The authors, M Laignel-Lavastine and M Paul Courbon, are in charge of the centre, under the military government of Paris, for the examination of soldiers who, in the absence of evidence of organic disease, are suspected of 'ill will" They divide functional states into two groups in the first the patient is unaware that he is the originator of the troubles of which he complains, and is therefore sincere in making himself out to be ill, here are placed those psychoses characterised by impairment of the critical faculties, notably hysteria In the second group the abnormal functional manifestations are directly dependent on the conscious "mauvaise volonte" of the patient, to be consciously aware of being the cause of his own complaint is the mark of the simulator In the latter case the physician, recognising the illegitimate nature of the symptoms complained of, may distinguish three categories (1) somatic disturbances, comprising mutilation and "pathomimia,' or the artificial concoction of a diseased condition, (2) functional disturbances or simulation properly so called, (3) functional disturbances grafted on a genuine organic affection, including exaggeration and perseveration The diagnosis of malingering is really a psychological problem, in other words, the question is whether the patient has or has not the intention of deceiving Now to detect an individual s intention is notoriously difficult, it is perhaps more prudent, therefore, merely to say, in a particular case, that there is no reason why the symptoms should not disappear But this attitude is obviously unsatisfactory when dealing with such cases as M Laignel Lavastine and M. Courbon have under their care, their task is to search the reins and the hearts and to face the risk of making mistakes If to ourselves our inner man is the sport of involuntary or unconscious deceits which render an exact determination of our motives all but impossible, how can we hope to settle analogous questions in others? The answer is that precisely this intimate deception does not impose or has less power of imposing on the outside observer Experience shows there are constitutional peculiarities in different individuals which determine the variations in their intention to deceive There is the pure simulator or malingerer without apparent excuse, who does not wish to risk his life or to undergo the fatigues of warfare Among the numerous types who advance some excuse may be distinguished the emotional simulator, who thinks he could never bear the sights of the battle field, the hypochondriac, who thinks his physique would not stand campaigning the man who pretends he would be more useful in less exposed positions or declares he has already done his bit,' or excuses himself by instancing the good fortune of some comrade Often too the patient begins to malinger at the instigation of his family or continues to do so to prove to the physician he has been wrongly accused of simulating It must be admitted that occasionally therapeutic mal adroitness suggests to the patient the idea of perpetuating his troubles, of the nature of which he was at first unaware Exaggeration is very frequently observed, perhaps the commonest is that where the exaggeration is scarcely conscious That symptoms may vary with the attention paid to them is not necessarily an indication of conscious deceit The authors discuss with some minuteness the forms that simulation actually takes once the idea has occupied the patient's mind They describe the active malingerer, who usually defeats his own purpose by challenging the observer's diagnostic power, the apathetic, who with oriental fatalism makes no reaction against the idea that he is ill, and who perseveres till the physician is exhausted, the sensitive, who eagerly falls in with the suggestions of the doctor and agrees readily enough that there is nothing the matter, yet persistently fails to throw off the influence of some trifling emotional factor With this sensitiveness is associated a sort of mental dilettantism, which is especially noticeable in those who have already been at the front, arriving home again it may be for some genuine though temporary condition The authors give a picturesque, yet none the less accurate, account of the devices to which the simulator has resort, and of the assumed attitudes of injured innocence, or of suspicious politeness, or of spurious anxiety to help in the unravelling of their case

A COLOUR WARD

Mr H Kemp Prosser holds the opinion that the colour of the surroundings has an enormous effect on the recovery of the sick, especially those who are depressed for one reason or another or are suffering from shell shock. An opportunity has been afforded him for carrying out his ideas by Miss McCaul, who has placed at his disposal a small ward in the McCaul Hospital in Welbeck street This ward he has had decorated according to his theories and the result is certainly very pleasing He claims that it is of the first importance to remove from the patient the idea of being shut in, an idea which is truly often a cause of great worry to some sufferers Therefore he paints the ceiling a bluish colour, so as to resemble so far as possible the blue of the sky, and the tint he employs he calls 'firmament blue" This blue is also used for a wide frieze The walls are painted a greenish yellow to represent the colour of foliage in spring, and the tint is called "Sunlight Primrose" A narrow slip of darker green separates the blue of the frieze from the walls The floor is painted with a yellowish green, containing certainly more green than the walls The window curtains are double, the inner curtains are mauve, and the outer curtains are pale yellow The furniture is tinted yellow, and the bedspreads are a warmer yellow The object of having the furniture of the same colour as the walls is that it may not be obtrusive, but, as it were, fade into the walls The fireplace is painted the colour of silver, and even the tea sets are chosen of a pale yellowish tint There is no pattern anywhere in the room, except that the upper edge of the bedspreads has a simple design, and over the fireplace a small painting hangs, representing a scene near Maidstone in early spring Mr Prosser maintains that it is essential that no browns or reds should be used, for these colours are saddening There is no doubt that this ward has a very cheerful effect, and we can well believe that the eyes of a man greatly depressed from shell shock or from some other cause would find in such a room as this no little relief from his depression, and this merely from the general aspect of the room Mr Prosser has devoted much trouble to carrying out his ideas, and though we do not endorse them fully, we feel that there is something to be said in their favour, anyhow we agree that the colouring of wards for the sick and wounded has been too little considered in the design of many hospitals The work of Mr Prosser will not have been in vain if it leads to more care being devoted to this aspect of hospital furnishing

PRIMARY TUBERCULOSIS OF THE TONSIL

IN an investigation made by Dr A Philp Mitchell for the Medical Research Committee, and published in the *Journal of Pathology and Bacteriology* (vol xxi), the author concludes that tuberculosis of the upper deep cervical glands develops from a primary focus in the faucial tonsils much more often than commonly supposed Primary tuberculosis of the tonsil cannot be recognised by the naked eye, but requires the aid of the microscope or of inoculation experiments Lesions tend to appear in certain sites, commonly just subjacent to the surface epithelium near the mouth of the lacunæ, less often in relation to the deeper portions of crypts, or deep in the tonsil close to the capsule 100 cases of cervical adenitis in children and 6 in adults were examined, and in 41 of them tuberculous lesions were demonstrated in the tonsil. With regard to the type of infection, the results indicate that in Scotland, at any rate, tonsillar tuberculosis is bovine in origin In a small percentage of children Dr Mitchell found both bovine and human types in the tonsillar crypts without demonstrable lesions either in the tonsils or elsewhere He concludes that, on the curative side, tonsillectomy is essential in all cases of tuberculous cervical adenitis in children, and, on the preventive side, that the only immediate safeguard is the sterilisation of all cows' milk supplied to infants and children The article contains a careful survey of previous work on the same subject, with an adequate bibliography The author has succeeded in throwing fresh light on a very important problem.

THE SURGERY OF THE NOSE FROM AN ÆSTHETIC POINT OF VIEW

THERE are few things of less real importance in itself than an ill shaped nose, yet though such a nose serves olfactory purposes, if it be of a very unusual shape it may cause its possessor real anguish All owners of an eccentric proboscis have not the qualities of Cyrano When the sufferer seeks the aid of his own medical adviser he is usually told not to worry about a matter which is not of the least importance, and if the patient has the right temperament sounder advice cannot be given But in other cases, where there is something definite that might be done, and where the patient's mental distress is very real, we think his complaint should be met in a different spirit In a recent issue of THE LANCET we printed a paper by Dr Julien Bourguet, of Toulouse, in which he described briefly the methods which he employs to remedy certain nasal deformities, and he gives illustrations of some of the patients on whom he has operated, showing the original conditions and those left after operation He thus proves how much may indeed be done by care and skill in many cases Most of the results have been very good, for one important point in the method employed by Dr Bourguet is that all the operative procedure is done from within the nose, the incisions being made through the mucous membrane, so that there is no external incision and no external scar It is hardly necessary to say that in this country also there are surgeons who practise these cosmetic operations with success and the numerous cases of nasal deformity which may be found among the wounded in the war offer a fine field for much good work, which should not be invariably closed by the suggestion to the patient that he had better put up with a trouble which does not affect his general health. Of course, a more difficult problem faces the surgeon who has to deal with cases where the nose is completely destroyed than where he has only to remedy an ugly shape Here there can be no question of a slight operation, any operation that is done must be extensive and thorough, if the result is to be anything more than a travesty of a nose The result cannot be called satisfactory unless it satisfies the patient, for the operation is only undertaken for the purpose of giving the sufferer relief from the annoyance of being without a nose Since the days of Tagliacozzi the operation of rhinoplasty has had many exponents, and in favourable cases the results have been excellent, satisfying even the most exigeant of patients, while the operation devised and first practised in India may give results leaving little to be desired There are, however, many cases of destroyed nose where the conditions of the tissue in the vicinity render thorough operation impossible Some time ago[1] we published an illustrated account of nasal prosthetic feats Lieutenant Derwent Wood, A.R.A., there showed, with the aid of some striking illustrations, the marvellous improvement which may be effected in the appearance of patients by the aid of masks of greater or less extent, according to the individual cases Mr Wood s knowledge as a sculptor enables him to imitate as perfectly as possible the former condition of the face so that the patient may look as he looked before The war has provided no small number of cases for the exercise of skill in these cases, and in many cases a marvellous alteration for the better can be accomplished

IRITIS AND OPTIC NEURITIS FROM TONSILLITIS

THAT tonsillitis may be the starting point of many forms of systemic infection and of inflammation in other organs such as endocarditis, pneumonia meningitis and nephritis, has been recognised in recent years Though the relation between iritis and other forms of ocular inflammation and septic foci in other parts has been emphasised in the same period the importance of the tonsil as a source of infection is not sufficiently recognised In the *Boston Medical and Surgical Journal* Dr I Sobotky has reported a case of iritis and optic neuritis following tonsillitis in which tonsillectomy was curative thus confirming the connexion A woman aged 21 years convalescing from acute follicular tonsillitis was seen on Oct 19th 1915 She showed enlarged and tender cervical glands and extreme congestion around the right cornea She gave a history of attacks of tonsillitis, usually at yearly intervals and followed after a week by inflammation of the eyes In the present attack the right eye was very painful and sensitive to light She was sent to the Massachusetts Eye and Ear Infirmary, where the following record was made "Oct 20th Iritis of right eye Optic neuritis of both eyes Pupil well dilated and regular Upper lid slightly swollen No evidence of syphilis Oct 25th Less pain in right eye Left eye, slight ciliary congestion Oct 29th Nasal examination shows rhinitis and diseased tonsils X ray report Teeth and accessory sinuses negative Dr Quackenboos agreed with Dr Sobotky that the tonsils should be removed On Nov 4th this was done They showed chronic inflammation and the crypts were filled with caseous material The Wassermann reaction was negative On Dec 14th both optic discs were swollen to at least two diopters with some dilatation of the vessels On Jan 11th, 1916, the swelling had diminished On March 1st, but for slight blurring, the discs were normal. On Jan 25th, 1917, the patient resumed work as a stenographer and has remained quite well since that date

NOTIFIED VENEREAL DISEASE IN CHRISTIANIA

IN his annual report for 1916 on venereal disease, reprinted from *Tidsskrift for den Norske Laegeforening*, P Schou, medical officer of health of Christiania, gives an account of the system of notification adopted in that city Though the report contains much interesting statistical information, it omits many details which, to readers unacquainted with legislation on venereal disease in Norway, would have given a more comprehensive survey of the subject 3240 new casse of venereal disease were notified, of which 1930 were gonorrhœa, 405 soft sore 860 acquired syphilis, and 45 congenital syphilis Of cases of extragenital infection there were 12 of primary syphilis of the lip, 8 of the tonsils, 1 of the abdomen, and 1 of the second finger of the right hand In 70 cases the notifications contained information which led to investigation of the source of infection, and of these the search resulted in disclosure of the sources of infection in 43 cases According to information received the medical officer of health and the assistant woman doctor examined 21 men and 25 women, of whom 1 man and 1 woman were "found" by the police Five men and 4 women, instead of attending on the medical officer of health, let themselves be examined by other doctors and produced certificates, of these patients 3 men and 4 women proved to be infected None refused to be examined Of the notified patients, 140 men and 1 woman declared they had been infected outside the town, and of these a large proportion were sailors whose infection had occurred in foreign ports The number of those infected outside the town was evidently greater but some doctors did not specify the place of infection on notification With the best of intentions the notifying doctors must probably often have found it impossible to provide this information As regards marital infection, 22 women and 14 men notified their consorts as the source of infection On account of intimate association with patients suffering from venereal disease (relations adopted children, &c) 6 men and 7 women were examined, with the result that 1 woman was found suffering from syphilis and 1 from gonorrhœa The report does not, however, state how the disease was contracted in these two cases Further, 460 men and 138 women were examined by the medical officer of health and the assistant woman doctor after having voluntarily reported themselves to the medical officer of health in order to receive treatment or to be sent to hospital. Of the total number of patients examined, 28 men and 60 women were admitted to hospital The Board of Health defrayed the expenses of special treatment for 209 men, of whom 69 suffered from syphilis The woman doctor treated 49 women and 2 children at the Board of Health Of these, 32 women and the 2 children suffered from syphilis Certain cases of venereal disease which were given ambulatory treatment by the Board of Health were also given free medicine, this raised the cost during the year to kroner 3862, as compared with kroner 2782 in 1915 One notification dealt with a case of infection with syphilis after treatment with salvarsan The medical officer of health approached the police 22 times with a view to securing their help for revealing sources of infection One woman was admitted to hospital by the help of the police The police notified 19 women and secured one conviction of offence against the law that any person who knows that he or she suffers from venereal disease and yet indulges in sexual intercourse or exposes another person to infection is liable to punishment up to three years' imprisonment Dr Schou does not state what penalty followed this isolated conviction, nor does he say why convictions were not secured in the other cases notified by the police That they secured only one conviction out of 19 cases is, however, in itself an eloquent testimony to the difficulties encountered in legislative attempts to penalise the spread of venereal disease

THE ORGANISM OF TYPHUS

IN the third number of *The New East*, a monthly review of "thought and achievement in the Eastern and Western worlds," published in English and Japanese at Tokyo, appears a short summary by Professor Futaki and his colleagues of the present position of the search for the causal agent of typhus Typhus was introduced into Japan from Russia in 1914, and the epidemic since occurring has afforded ample opportunity for etiological study So far various competing agents have held the field bacilli described by Ricketts and Wilder, intra leucocytic bodies by Nicolle, both in 1910, a diplobacillus noted by Rabinowitsch and a diplococcus by Furth in 1912, other intra corpuscular bodies seen by Prowazek, and recently cocci again by Plotz and his co workers After carefully examining these rival claims Futaki reported to the Japanese Congress of Internal Medicine in April, 1916, his inability to confirm any of them from his own observation, adding his conclusion that the virus was either a free, non visible corpuscle or a minute spirochæte After finishing an investigation into rat bite fever with the isolation of a spirochæte the Japanese observers have now done the same for typhus In April of this year a spirochæte was found in the lumen of a kidney tubule in a patient dead of typhus, and similar organisms in the next seven cases examined except one at a very late stage of the disease Later spirochætes were found in the urine of patients in an early stage, and injections of blood from one such made into a *rhesus* monkey gave rise after nine days' incubation to an illness in which similar spirochætes were found in kidneys and urine The organism is described as resembling in form the *S pallida*, 6 8 μ in length, with 5 7 windings, and a short cilium at each extremity It stains with silver and Giemsa. Dr Futaki and his colleagues at the Imperial Institute for Infectious Diseases, Tokyo, believe the organism they describe to be the causal agent of typhus, and propose for it the name of *S exanthematotyphi* The name is correct but cumbrous in Western characters, and if the Japanese organism, as seems probable, retains its place, we might prefer to call it *S japonica*

ANNUAL REPORT OF THE CHIEF VETERINARY OFFICER FOR THE YEAR 1916

THE report for 1916 of the Chief Veterinary Officer of the Board of Agriculture and Fisheries (published by H M Stationery Office) shows that the problem of combating the diseases of animals at home must not be neglected, even though the thoughts of everybody are concentrated on war and war areas England, from its insular position, is especially fortunate in regard to its ability to prevent the entry of suspect animals from abroad, as it is enabled to enforce quarantine precautions, and for this reason there are some maladies which continental veterinary authorities are called in to deal with which do not exist with us However, some of these contagious diseases still gain an entrance, and this in a manner at present not satisfactorily explained, but the necessity of careful attention to home matters as well as those outside the island of Great Britain itself is thus demonstrated Foot and mouth disease of cattle is an instance of this, an outbreak of which occurred on Feb 10th at a place as far away from a port of cattle debarkation as Shepton Mallet in Somerset By the skill of the veterinary inspector it was diagnosed and reported, and the Board of Agriculture confirmed and dealt satisfactorily with it Careful inquiries, however, failed to detect the origin of the outbreak In the report the other scheduled diseases are dealt with, particularly swine fever, swine erysipelas, tuberculosis, glanders, anthrax, and sheep scab 4331 outbreaks of swine fever were confirmed, an increase of 337 on the previous year Serum treatment was accepted by the owners in 83 per cent of suitable cases, the results showing a benefit of 17 per cent in favour of pigs on premises where such treatment was applied Serum treatment being preventive and not curative successful results depend largely on getting early in touch with outbreaks Greater finality is hoped from treatment with sero vaccine, which is still on its trial, since the mortality from the treatment itself has been considerable About 9000 specimens were examined and reported upon in the Veterinary Laboratory—altogether a busy year s work when many of the staff are away on active service

AN exhibition of war specimens, collected by members of the Royal Army Medical Corps and prepared by members of the museum staff of the Royal College of Surgeons, will be opened in the museum of the College, Lincoln's Inn fields, W C, on Thursday, Oct 11th, at 3 P M, by Sir Alfred Keogh, G C B, Director General of the Army Medical Service At the same time the Council of the College will present its honorary Fellowship to Sir Alfred Keogh

THE CONTROL OF VENEREAL DISEASES

National Council for Combating Venereal Diseases

THE question of the artificial prophylaxis of venereal disease has been discussed at a recent conference of the National Council and at two meetings of its Executive Committee A special meeting of the Council is to be held on Monday, Oct 15th at 8 30 P M., at 1, Wimpole-street W., to consider the following resolution submitted by the Executive Committee —

> In view of the public attention now directed to the whole subject of prophylaxis the Executive Committee, after careful consideration, is not prepared to depart from its original position, in which, in accordance with the spirit of the Royal Commission's Report it refrained from recommending the adoption of prophylaxis—i.e. the provision of outfits to men before sexual indulgence The committee strongly urge the importance of the making of arrangements for the early treatment of venereal disease even before the outset of symptoms.

An informal discussion on the progress of the movement between members of the executive and other committees and the members of the National Council will take place at a reception to be held at the Grafton Galleries at 8 30 P M on Tuesday Oct. 16th, when delegates from the various branches will be present.

Measures Taken in New South Wales

Speaking at the recent annual general meeting of the Royal Prince Alfred Hospital at Sydney Sir Thomas A. Stuart, chairman of the board of directors spoke of the work of the evening venereal clinics instituted in 1915 at the request of the State Government Before the establishment of these clinics a large number of cases were not treated at all or were treated by quacks The Royal Prince Alfred Hospital was the only institution responding to the Government's appeal with the result that patients came in crowds and overwhelmed the resources of the hospital. In 1915 more than 2000 cases were on the books during the year, while in 1916 the number was 2643 On one occasion it was necessary to call in the police to assist in maintaining order and the board was reluctantly compelled to reduce the numbers admitted to the clinics The hospital has 30 beds for women and children suffering from venereal diseases and has served as a model for the establishment of similar clinics in three other States and in New Zealand

Sir Thomas Stuart referred to a report made to him by the medical superintendent of the hospital, who had just returned from Egypt where he had been instrumental in carrying through certain preventive measures A prophylactic or preventive tent was established at the entrance of each camp for men returning to their quarters after having exposed themselves to infection. Of a certain series of 2000 cases only three developed disease while in another series in the first month after the system had been established of 432 men who were attended to in the tent not one became infected, while of 35 men who developed the disease not one had visited the tent Acting on this report the Commonwealth Defence Department has established similar arrangements at each military camp in the several States

Enlightenment Campaign in Victoria

The Public Health Department of the State of Victoria has issued a 16 page pamphlet dealing in popular manner with venereal diseases (1) the causes symptoms and results of venereal diseases, (2) the provisions of the Venereal Diseases Act (3) directions to parents and guardians regarding children suffering from venereal disease, and (4) the provisions relating to advertisements

The provisions of the Venereal Diseases Act 1916 may be briefly summarised as follows 1 Any person suffering from a venereal disease shall forthwith, on becoming aware of his condition consult a medical practitioner either privately or at a hospital or clinic and shall also supply his correct name and address Failure to do so renders him reliable to a penalty of £20 It is illegal for any person other than a medical practitioner to treat venereal disease Chemists are not allowed by law to treat any person suffering from venereal disease 2 Every patient who is under medical treatment shall continue under treatment until he has received a certificate of cure 3 A patient may change his medical adviser but if he does so must inform his new adviser of the name and address of his last adviser 4 A person suffering from venereal disease and not being treated by a medical practitioner may be apprehended, after due warning and detained until cured 5 No one shall knowingly infect any other person with a venereal disease, or knowingly do or permit or suffer any act likely to lead to the infection of any other person with such a disease Penalty, £100 or 12 months' imprisonment or both. 6 No one suffering from venereal disease shall prepare or handle food intended for consumption. 7 Anyone suffering from venereal disease shall take all reasonable precautions to prevent spread of infection and shall carry out the directions and instructions of the medical attendant

The provisions relating to advertisement prohibit under penalty of fine or imprisonment anything in the nature of a public advertisement relating to venereal diseases, nervous debility, or to the treatment of complaints peculiar to women. The offender is liable to summary arrest Any person printing or distributing such advertisement is also liable to severe penalty And any newspaper or any printed or written matter is prohibited from entering Victoria if it contains reference in the nature of an advertisement to the conditions mentioned. A protective clause runs as follows "No offence, however will be committed by any person who prints publishes distributes delivers or posts any *boná-fide* medical or pharmaceutical book, pamphlet, magazine, or periodical or any work of recognised literary merit relating to the conditions referred to"

Bombay League for Combating Venereal Diseases

The Bombay Sanitary Association, which was founded in 1903 with a view of coöperating with the Health Department in educating the public on matters of hygiene and sanitation, held a conference on March 6th and 20th 1917 to discuss the incidence and control of venereal diseases in Bombay, at which the following resolutions were passed —

> 1. That in view of the great prevalence of venereal diseases in Bombay and of their grave consequences, this conference of medical men assembled is of opinion that the time has come when the public and the State should be roused to the gravity of the situation, and induced to take measures to prevent them.
>
> 2. That a league for combating venereal diseases and consisting of medical and lay men, be formed to educate public opinion and to devise and assist in carrying out all such measures as are calculated to prevent the spread of these diseases.

A provisional committee was appointed to take the necessary steps for the formation of the League, with the Hon Mr G S Curtis C.S.I., I.C.S., as president, Surgeon-General R. W. S Lyons M.D., I.M.S and Sir Fazulbhoy Currimbhoy as vice presidents, and Dr John A. Turner C.I.E., and Dr Lemuel L Joshi as joint honorary secretaries At a later meeting of this committee the aims and objects of the League were defined as follows (1) To provide accurate and enlightened information as to the prevalence of these diseases and as to the necessity for early treatment, (2) to promote the provision of greater facilities for their treatment, (3) to increase the opportunities of medical students and practitioners for the study of these diseases, (4) to encourage and assist the dissemination of a sound knowledge of the physiological laws of life in order to raise the standard both of health and conduct, (5) to coöperate with existing associations to seek their approval and support and to give advice when desired, (6) to arrange in connexion with such organisations, for courses of lectures and to supervise the preparation of suitable literature, (7) to promote such legislative social, and administrative reforms as are relevant to the foregoing aims and objects

Dr J A Turner read a paper at the conference summarising the work being done in England and suggesting measures of control in Bombay The scheme he outlined involved an initial outlay on dispensary and clinic of R.5000 with an annual cost of R.20 000 for maintenance. Dr A Powell described the course of syphilis among the Indian community summarising the distinctive characters as follows Syphilis does not by any means run exactly the same course in Indians as it does in Europeans Hence European practitioners fresh from European schools look out for—and miss—the signs common in Europe They find but do not correctly interpret those common in the indigenous people of this country 1. Sore throats are much less common in India. 2. Rashes are less common. In a country where prickly heat and ringworm abound rashes are easily overlooked especially by the patient. 3

---

[1] The address of the National Council [illegible] is [illegible] Avenue Chambers, [illegible] London, W.C. Tel.: Museum [illegible]

Tabes and G P I are infinitely less common in India 4 Obscure "rheumatic" pains in the joints, bones, and muscles are infinitely more common, more severe, and more persistent in Indians, in fact, they are often almost the only secondary and tertiary symptoms Genuine "acute rheumatism," "rheumatic fever" with its cardiac complications, is very rare among Indians 5 Disease of the arteries is much more common in India It is especially common in the ascending arch of the aorta and in the coronary arteries 6 Disease of the aortic valves is more common than disease of the mitral valves in India

REPORT FOR 1916 OF THE COUNTY MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER OF LONDON[1]

Dr W H Hamer's fifth annual report in each of these capacities has just been issued Not farther back than last November his report for the preceding year was noticed in these columns[2] The appearance of the present volume after this brief interval indicates commendable promptitude Readers of the last two reports will miss the instructive series of diagrams which illustrate the volume for 1914 That their actual publication has been discontinued since that year is due to economic considerations But from the present context it is evident that their compilation is still in progress, and we may therefore hope that on the return of peace conditions this impressive method of graphic representation will be resumed in the published reports

PART I—PUBLIC HEALTH

The health of London in 1916 compares favourably with that of the preceding year The medical officer warns us, however, that the estimates of population available are still less trustworthy than were those of 1915, a fact that must be remembered in comparing the statistics of successive years When the National Register was compiled two years ago the marked local changes caused by war were only then beginning Consequently that register, which had never been quite reliable, could not be regarded as even approximately forecasting the subsequent movements of population The weather conditions of last year were phenomenal, and doubtless accounted in some measure for the substantial saving of life among infants, as well as for the unusual freedom at other ages from the ravages of infectious diseases In the year 1916 the flow of water under London Bridge was greater than in any previous year on record The floods of the early part of 1915 had been the highest since 1894, and there followed in the year under review a flow of water in the Thames of 875 thousand million gallons Apart from abnormal weather conditions, the study of sickness and death rates is complicated by disturbances incidental to war

Vital Statistics

The marriages in London during 1916 were fewer by about one third than those of the previous year, the decrease being greatest in the second half of the year The abnormally high number of marriages during the progress of hostilities probably corresponds fairly with the movements of enlistment Difficulties arise in calculating a marriage rate for comparison with pre-war figures, owing to the circumstance that the data include men on active service, while the published estimate of population relates to civilians only The Registrar General calculates a rate of 19 per 1000 for 1916 In the previous year it probably amounted to about 26 For analogous reasons the computation of a reliable birth rate is beset with difficulty The birth rate of the year under notice is officially estimated at 21 5 per 1000, against 22 5 in 1915, these rates may be generally compared with 25 the average in the quinquennium before the war—viz per 1000

Effect of war conditions on mortality—The Registrar General calculates the death rate of 1916 at 14 7 per 1000 of the civil population The rate of 1914 had been 14 6 calculated on the total population in the middle of the year Thus, with fewer deaths in 1916 the mortality is stated to have been higher This, however is an anomaly depending solely on the use of a civil population, without correction for changes among the living resulting from the withdrawal of males of military age—a period of relatively low mortality In the absence of hostilities the death rate of last year would have been below that of 1914, and probably would have barely exceeded 13 6 the low rate of 1912. At most ages the mortality in 1916 shows a decided improvement upon that of 1914 The decrease in the deaths under one year is partly due to the still falling birth rate, but not more than 10 per cent thereof can be thus accounted for The rate of infant mortality last year was 89 per 1000 births, and was 2 per 1000 above the lowest rate hitherto experienced in London The favourable condition of moderate summer temperature has doubtless contributed to this result, but it is probable that the recent restrictions on the sale of intoxicants has had a large share in reducing the deaths from suffocation, and perhaps also from prematurity It is worthy of mention that the decline in mortality has not taken place among infants *pari passu* with the decline at the higher ages, on the contrary, it has only become conspicuous during the current century, and particularly within the last seven years

Infectious diseases—The behaviour of infectious sickness last year was essentially similar to that in 1915 London suffered no disaster from the spread of typhus fever, and in spite of the importation of a few cases of small pox that disease never obtained a foothold. The civilian notified cases of scarlet fever numbered 8746, or about half the total reported in the preceding year, and about one-third the total in 1914 There were fewer attacks in 1916 than in any year since 1891, when notification first became compulsory The cases of diphtheria notified among civilians numbered 8743, differing little from the totals in each of the two preceding years Enteric or typhoid fever still continues to decline The notified attacks in 1914 had numbered 789, and in the following year 607, whilst there were only 461 in the year under review Among many possible sources of infection fish or shell fish were inculpated in 85 instances The year 1916 was the fifth in succession in which there was marked smoothing out of the autumnal rise in London The experience of last year confirms that of 1915 respecting the complete failure of evidence of increased spread of infection by human agency For, after making due allowance for the absence abroad of susceptible persons, the prevalence of typhoid in London in the last two years has been actually lower than ever before known despite the addition to the community of an appreciable number of typhoid convalescents from abroad On the other hand, recent phenomena tally well with the theory of food causation It is noteworthy that, as the late Dr H T Bulstrode asserted in his reports of 1896 and 1911 a steady improvement has been brought about in the last 20 years by the elimination of dangerous shell fish As regards further reduction of typhoid fever, there is reason to believe that more benefit is likely to result from pursuing the older epidemiological methods than from giving effect to the new principles advocated by Koch and his followers In particular, further care for the purity of shell fish layings and entire prohibition of the sale of ungutted flat fish are to be looked upon as the main lines upon which further advance can be made

Phthisis—The civilian deaths from phthisis in the year 1916 numbered 6491, as compared with 6875 in 1915 and 6476 in 1914 At military ages there was a decrease last year on the deaths registered in 1914 The calculation of a mortality rate for the civil population from the above figures would give a result in no respect comparable with pre war rates, for not only has the war left on the civil population practically all the pronounced phthisis, but a portion of the fatal cases among persons accepted for service, and among those subsequently discharged for tuberculous disease, are recorded as civilian deaths

Cerebro-spinal fever—In the course of last year 425 cases of this disease were notified among the civil residents of London, or fewer by 202 than in 1915 These figures do not include posterior basal meningitis The Registrar General tells us that in London cases of the last-named disease are notifiable under the head of cerebro-spinal fever, whilst elsewhere there is no uniformity of classification In view of this and other difficulties computation of fatality rates has not been attempted it being evident that records of death from cerebro-spinal fever for London bears no consistent relation either to the notified cases of that disease or to the actual number of deaths from this cause.

---

[1] King and Son, Westminster pp 42 Price 1s

[2] THE LANCET Nov 11th 1916 p 837 and Nov 25th 1916, p 913

Poliomyelitis—There was an increase last year in the attacks by this disease reported throughout the country generally In London 197 cases of poliomyelitis were notified the highest number previously reported having been 145 in the year 1913

PART II—EDUCATION

A large share of the energy of the County Council s medical staff continues to be devoted to matters connected with education Of the administrative difficulties encountered in the preceding year as the result of war conditions no abatement was experienced in 1916 Thanks to the special efforts made by the older men and by the women already employed as school doctors, the work of medical inspection has been prosecuted with considerable success Moreover the difficulty of securing the services of a sufficiency of qualified persons for the hospital treatment of school children has been satisfactorily met The further difficulty of retaining an adequate supply of nurses has been overcome by the Council, who have adopted financial measures against the further depletion of the nursing staff whose full efficiency is essential in this department of the public service The work of "following up has been rendered particularly onerous by reason of the serious defection of volunteers To meet this emergency the care committees of several adjacent schools have coöperated with the view of economising the work of home visitation, and thus carrying out the duty of following up in urgent cases albeit with a reduced number of visitors

Medical inspection and treatment—Of the children primarily examined by the doctors last year in elementary schools 88 415 or nearly one third, were found to require treatment for defects Reinspections were made of the children who at the first examination had been found ailing with the result that 41 7 per cent. had been brought under treatment within six months, as compared with 49 6 per cent in 1914 Between the authorities of maternity centres and the school medical service satisfactory cöoperation has been established. In two instances the premises of the school treatment centres are also used by the maternity centre for the treatment of mothers and of childern under school age Similar cöoperative schemes are in prospect at four other centres The open-air schools at Birley House and Shooter's Hill were kept open throughout the year Kensall House school for tuberculous children has also been continued and some of the playground classes have been held in the public parks Altogether 5422 children were examined during the year with a view of admission to special schools and of these rather more than half were certified as suitable for admission The remainder were either returned to elementary schools or were declared unsuitable for any of the Council s institutions.

Personal hygiene—There are now 24 cleansing stations in London at 20 of which scabies is admitted for treatment more than 3000 children suffering from scabies were given not fewer than 17 000 baths in the course of the year Examination was made of 988 000 children, 25 000 of whom were found to be verminous Of these, 13 000 were were cleansed by the authorities and 11 000 by the parents Verminous children attending schools in outlying districts are now brought under the scheme and are conveyed to the cleansing stations in ambulances Moreover in certain instances borough councils are now giving special facilities for hot baths to be obtained by school children and members of their families

Malnutrition and emaciation—At the present time children suffering from that degree of malnutrition which is known as wasting are rare in our schools Conditions leading to emaciation are now detected at an early stage the sufferers being promptly referred to appropriate agencies for relief In the course of last year only 0 4 per cent of the children inspected were placed in this class against 0 51 in 1915 From figures relating to the last four years it appears that the general state of the children has been better during the war than in the period immediately preceding The yearly improvement of previous years in clothing and footgear as well as in general cleanliness has been fully maintained during 1916 This fact is presumably attributable in some measure to better economic conditions but it is doubtless largely due to the maintenance of medical and cleansing work carried on for some years past in connexion with the schools The continued improvement of the children which is revealed at the medical inspections testifies to the success of the arduous work of the school nurses "These splendid results, writes Dr Hamer, "which show that none of the horrors of war have been allowed to affect the general condition of the children or to interfere with the growth of that solicitous care for their welfare which has distinguished recent years are a matter for profound joy and satisfaction. They may well encourage us to face the future with complete confidence, for a community that can thus protect its children while putting forth the most prodigious martial efforts the world has ever seen, must be sound to the core" The dominant influence of social condition is manifest in the returns of the various parts of the metropolis A map showing the nutritional state of the children would correspond generally to one showing their social condition That this is so is abundantly evident from the report In the year 1913 a special study was made of the health of children of school age In a report respecting nearly 1000 of these children the close connexion of tuberculous disease with malnutrition was emphasised tuberculosis being definitely recognised in 19 per cent. of the cases examined, and its presence being suspected in a large additional proportion

Infectious diseases—The year under review was remarkable for exceptional freedom from infectious disease among school children In the case of scarlet fever the returns are particularly satisfactory In certain weeks of August and December the scarlet fever notifications throughout the metropolis were fewer than 100, being only about one-third the average in the corresponding weeks of the previous four years As causes producing this result the effect of altered nomenclature of climatic influence, and of flea prevalence are here reviewed, and the important question of the relationship of scarlet fever is considered. As regards flea prevalence, we note that examination of the flea and scarlet fever curves in the last eight years reveals a striking correspondence in their annual variations Among measures for limiting the spread of scarlet fever the importance of hospital isolation is taken for granted and the fact is referred to that the low level reached by that disease in 1916 has fortunately liberated for other uses many additional beds in the hospitals of the Metropolitan Asylums Board In respect of epidemic throat illness the record of the year under notice was unique, inasmuch as the notifications of diphtheria actually exceeded those of scarlet fever for the whole year whilst from Septembar onwards the excess was marked The strange comment was made in some quarters that the position was a serious one, inasmuch as diphtheria was more widely prevalent in London than scarlet fever, the real explanation being, of course, that the figures for scarlet fever were so exceptionally low as to render those for diphtheria unsatisfactory by contrast As long ago as the eighteenth century much confusion prevailed with reference to epidemic throat disease. It was not until 1831 that the term 'diphtheria was employed, up to 1855 the two diseases in question were classed together by the Registrar General, and in German statistical returns the heading Scharlach diphtherie" has continued in use till now The discovery of the diphtheria bacillus by Klebs and Loeffler in 1883 and 1884 led to the adoption of bacteriological methods for confirmation of the diagnosis of diphtheria and probably as a result there has been an increasing use of that term during the last 30 years The relationship between dry years and one or both of these conditions has been exhaustively analysed by Dr J B Longstaff and Sir Arthur Newsholme Dr Longstaff found the correspondence close in the sixties' and early seventies but less marked in later years Whilst Sir Arthur Newsholme dealing with diphtheria alone concludes that the essential factor in the production of epidemic and still more of pandemic diphtheria is the occurrence of a succession of years of deficient rainfall, associated as they must be with abnormally dry conditions of the soil and subsoil

DONATIONS AND BEQUESTS—The committee who are distributing the residuary estate of the late Mr Leopold Salomons have allocated a further £50 000 to hospitals.

PARIS

(FROM OUR OWN CORRESPONDENT)

The Importation of Malaria into France

I HAVE several times mentioned the existing fear that subjects of malaria, who are returning to France in great numbers from the Salonika Forces, should prove sources whence malarial disease may develop in their native country Against this apprehension it has always been urged that the intervention of particular kinds of anopheles is required, and that the culices and anopheles met with in France are inoffensive For prudence sake however, it has been recommended that hospitals reserved for the subjects of malaria should be placed in localities where there is not much stagnant water or many breeding places for gnats Definite proof now comes that fears on the subject were not exaggerated and that the hæmatozoa of oriental malaria can be transmitted by our indigenous anopheles, which seem to be capable of this new and regrettable adaptation M Victor Raymond and M Grysez proved the possible occurrence last spring of cases of malaria among soldiers coming direct from regions in France where the disease is unknown, but who had occupied trenches where the soldiers preceding them had returned from Salonika, having contracted malaria, the *terrain* was flooded and mosquitoes abounded there, among them several kinds of anopheles A confirmation of the possibility of outbursts of malaria, derived from the East, and one having great weight, has now been furnished by M Laveran, who has presented to the Académie des Sciences a research carried out at the Pasteur Institute by M Rouband M Rouband has submitted to bites from indigenous anopheles malarious subjects who have returned from Salonika with the disease upon them He has found in the proboscis of these anopheles living hæmatozoa, and having submitted himself to bites succeeded in contracting malaria of a characteristic form, with periodic febrile accessions and the presence of hæmatozoa in his blood M Laveran concludes from this that it is necessary to keep the victims of malaria away from regions where the mosquito abounds, and to instal on elevated plateaux, where the nights are cold, hospitals reserved for them, the beds being furnished with nets Otherwise there is, he says, a risk that after the war malaria may invade France and render it, or at any rate our warmer regions, as unhealthy as the oriental plains

Breastplates for Soldiers

Inspector General Delorme has called the attention of the Académie de Médecine to the frequency and immediate gravity of penetrating wounds of the thorax and abdomen These represent an enormous proportion of deaths on the field of battle while the adoption of steel helmets has considerably diminished the total of grave wounds of the skull Wounds of the heart, big vessels lungs, and abdominal viscera account for the chief part of the mortality among those of the wounded who die before there is time to render them proper care These wounds in a trench war are due, not for the most part to rifles or machine guns, against which there is no possible protection, but to the bursting of explosive projectiles, hand grenades or shrapnel all of which inflict wounds with a relatively feeble initial velocity, so that a method of protection, which would be powerless against bullets, would meet the case In view of the excellent results given in head wounds against the same sort of projectiles by the steel helmet now used by all the soldiers, M Delorme proposes that the troops should be provided with a breast-plate of the same metal and thickness suspended round the neck and covering entirely the front of the trunk from the root of the neck to the pubis the weight not being greater than that of the helmet, this breast-plate could be placed over the back when kneeling in the trenches or when lying flat on the stomach The Académie de Médecine has unanimously decided to invite the Minister of War to submit the idea to practical experiment

The Disappearance of Small-pox from Paris

At the last meeting of the Seine Board of Health Dr Roux, of the Pasteur Institute reported on the results of small pox vaccination in Paris during 1916 The 800,000 vaccinations performed in Paris at the outbreak of the war and during the year 1915 resulted in the disappearance of small pox from the city, and in spite of the fluctuation in population due to mobilisation, and of the fact that Paris had given shelter to a number of refugees from the invaded districts, the capital remained immune from small pox. This had occurred although all the conditions favourable to the breeding of the disease were notably present, among immigrants both morally and physically reduced, of whom the greater number had not been revaccinated and some not vaccinated at all Small pox infection was repeatedly introduced from outside sources without spreading in the city Dr Roux considers that a prolonged war without small pox is a remarkable fact, proving the efficacy of the prophylactic measures taken The honour of the achievement is due to the vaccination service as well as to the public, which has eagerly responded to the appeals addressed to it by the Government in placards and newspaper advertisements During the year 1916 only a single case of small pox was notified in Paris, and one case was imported from Algiers The latter was an Arab who had not been vaccinated in infancy, and who arrived in Paris during the period of incubation, he was admitted to the hospital Claude Bernard, where he died This Arab worked in a factory where 1000 men were employed, living with his brother The workmen and the brother were vaccinated on the day the disease was recognised and not one of them contracted it

Antirabic Inoculation at the Pasteur Institute in 1916

During the year 1916 1391 persons underwent preventive inoculation at the Pasteur Institute in Paris, six died of hydrophobia, giving a gross percentage of 0 43 But two of the patients developed the disease while still under treatment, and one died less than a fortnight after its conclusion Deducting these three, the revised statistics stand Persons treated 1388, deaths from hydrophobia, 3, mortality, 0 21 per cent

Improved War Bread

The war bread used in France, made from 85 per cent flour, has given rise to much complaint The grey black colour and unpleasant taste have disgusted a number of consumers, with the result that a large amount has been wasted, and the question has arisen whether economy would not be better served by providing bread made with normal flour and limiting its consumption by a special bread card It is not disputed that the present bread keeps badly and quickly undergoes acid fermentation, leading to gastric and intestinal disorders in persons predisposed to dyspepsia. The researches undertaken by MM Lapicque and Legendre at the Ministry of Inventions have now made it possible to grind the flour to the 85 per cent standard and still avoid the greater part of the objectionable qualities They have shown that the constituent of war flour eliminated from 70 per cent (white), known by millers as *recoupettes*, is the part which deteriorates by fermentation and gives rise to acid products By alkalising the flour when it is mixed this injurious fermentation is held in check. M Lapicque bases his conclusions on a simple experiment which can be readily confirmed A piece of slaked lime wrapped in a piece of cloth and held by a string is placed in the bowl from which the baker takes his water for making the dough The quantity of lime which dissolves under these conditions is 1 1000 and exactly the proportion required for checking fermentation, it is therefore only necessary to see that the lime is renewed when exhausted The manufacture involves practically no extra trouble to the baker, while the increase in cost is trifling less than 5 cts for 3000 kilos, 1 gramme of lime being sufficient for 3 kilos of bread The quantity of hydrated lime introduced into the daily diet of the consumer does not exceed 10-20 centigrammes, of which the greater part becomes carbonate during the leavening This amount is harmless, being indeed not greater than that contained in a glass of milk The new war bread is much superior to the old, the dough is well risen, whiter and not viscous, the smell is pleasant and not acid, the crust is excellent The bread keeps well and its digestion does not lead to any disorder The public has been quick to appreciate these advantages, and bakers who have begun to make the bread according to official instructions based on a communication by Dr Lapicque to the Academies of Medicine and Sciences have soon been obliged to increase their bakings It is a curious fact that even animals have noticed the difference between this bread and the other, and having once tasted the new refuse the old.

Joy riding for Whooping-cough

It has long been known that convalescence after whooping cough is accelerated by change of air, by movement from one locality to another, whether from town to country, or from one part to another of the same country From these observations Dr Challamel claims to have deduced an original therapeutic method He assumes that intense oxygenation of the lung is the cause of improvement and therefore utilises the effects of motor driving in the fresh air Under the influence of rapid transit through the air intrapulmonary pressure is probably augmented, with increased ventilation of the air cells The effect is in fact, the same as in the compressed air chamber, but the joy-ride affords a practical method within the reach of all The author has brought to the notice of the Therapeutical Society several cures effected by this treatment, which he has begun to practise at early stages of the disease, as soon as the temperature has fallen A beginning is made with a ride of ½-1 hour at a slow speed in an open motor, the child s face being protected from dust, little by little the length and speed of the ride are increased The treatment can be carried out in all kinds of weather except actual rain, the presence of bright sunlight is not essential Cures have resulted after two rides and as a rule a few prove sufficient The only contra indications are fever and extreme youth The treatment should not be employed for children under the age of three months

Obituary.

DAVID CHARLES REES M R C S ENG L R C P LOND

Mr D C Rees whose death from typhus fever in Port Elizabeth South Africa was recently announced in the *Medical Journal of South Africa*, was educated at Charing Cross Hospital Medical School and after obtaining the Diploma of the Conjoint Board went out to Nigeria with General Lugard s Frontier Force He went up the Niger, saw service there and gained considerable experience in the diseases of the country On his return the London School of Tropical Medicine was just being opened, and Sir Patrick Manson immediately secured his services as the superintendent or as it was then called medical tutor of the school The first session opened on Oct. 1st 1899, and Mr Rees was responsible for organising the lectures and other details of the course So well did he do this that the general scheme adopted by him has held till the present day He was himself an able teacher and had a happy knack of interesting the early students in the laboratory work most of which was usually quite new to them In the summer of 1901 during the vacation he visited the experimental house set up by the School in the Roman Campagna for malarial experiments and he stayed there for several days with Dr L. Sambon and Dr G C Low, the experimenters He then returned to the school for the fourth session and worked in London till the end of the year finally, to the sorrow of all his fellow teachers giving up his appointment to take up the very important one of district surgeon and port health officer at Port Elizabeth Here the opportunity of combating plague and small pox presented itself and ably dealing with these Mr Rees made a name for himself in this line, that he should have died from typhus the disease he was trying to stamp out at the moment is very sad After taking up his residence in South Africa he did not have the time or opportunity to come much to London but he visited the capital on the occasion of his marriage and again three or four years ago when he renewed his old associations with the School of Tropical Medicine

There is little doubt if Mr Rees had stuck to tropical medicine that he would have become famous in that section of medicine Before leaving for Africa he wrote on tropical subjects to the journals and these contributions were always well written and carefully thought out, but work in Port Elizabeth did not allow him to keep up his literary activity At the time of his death Mr Rees was in his fiftieth year and he has left a widow and two children to mourn their loss To them we offer sincere sympathy and the London School of Tropical Medicine and all its teachers who knew and were associated with the deceased will offer them the same

The War.

THE CASUALTY LIST

THE following names of medical officers appear among the casualties announced since our last issue —

Killed

Capt B A Bull R.A M C attached London Regiment was educated at Oxford and at St Bartholomew's Hospital London, and qualified in 1915 Shortly afterwards he joined up

Died of Wounds

Capt F Hardie, R A.M C, qualified at Edinburgh in 1900, and was in practice at Southampton prior to joining up

Died

Lieut D Anderson, R.A M C

Wounded

Capt A. C Ransford, R A M C
Capt R G Abercrombie R A M C
Capt G A Macfarlane R.A M C
Lieut C B Simpson, R.A M C
Capt D L Tate R A M C
Capt F G Flood, R.A M C
Capt F A L'Estrange, R A M C, attached Rifle Brigade
Capt M McNiff, R.A M C attached Durham Light Infantry
Lieut G H Adam, R A.M C, attached Lancs Fusiliers
Capt F Black, R.A M C, attached Royal Engineers
Lieut C O Bodman R A.M C
Lieut Col G H L Hammerton, M C R A M C
Lieut J C Pearce R.A.M C, attached Yorks Light Infantry
Capt D O Riddel, D S O, R A M C, attached W Yorks Regiment
Capt W Turner, R.A M C

Slightly Injured

Surgeon A E Panter, R.N

CASUALTIES AMONG THE SONS OF MEDICAL MEN

The following additional casualties among the sons of medical men are reported —

Second Lieut J B Bailey, East Yorks Regiment, killed in action, only child of Dr J E Bailey of Beverley, Yorkshire
Second Lieut F J Chown Royal Flying Corps, killed in action, only son of Dr F Chown, of Townshend near Hayle, Cornwall
Capt R A. Eakin, King s Shropshire Light Infantry died of wounds only son of Dr J W Eakin of South Mimms, Barnet, and late of Trinidad
C M Richards killed in action only son of Dr M Richards, of Fremantle Western Australia
Second Lieut G D Rose Gordon Highlanders killed in action, second son of Dr G Rose of Aberdeen
Second Lieut E C G Hull Royal Field Artillery killed in action, elder son of Dr E G Hull of Streatham Common London
Flight Sub-Lieut N S Wright, R N, killed son of Dr W S Wright, of Wool, Dorset

FOREIGN DECORATIONS

French

Croix de Guerre —Major (temporary Lieut Col) L J M Deas I M S Temp Capt A L George, R.A.M C

THE HONOURS LIST

The following awards to medical officers are announced The acts of gallantry for which the awards were made are not yet announced All are members of the R A.M C unless otherwise stated The dates in parentheses in those cases where bars have been awarded refer to the number of THE LANCET in which a record of the original decoration will be found —

OBITUARY OF THE WAR

WILLIAM DUNCAN KIRKLAND, M B , Ch M Syd ,

MILITARY CROSS,

MAJOR, AUSTRALIAN ARMY MEDICAL CORPS

Major W D Kirkland who was recently killed on active service at the age of 26 years, was elder son of the late Lieutenant-Colonel Hugh Kirkland M B , Ch.M Glasg , A A M C Born at Bathurst, N S W , he was educated at Coerwell Academy, Bowenfells, matriculating in 1908 Entering St Andrew's College Sydney, he graduated in medicine, with honours, in March, 1913, and became resident medical officer at the Royal Prince Alfred Hospital and later radiographer After a brief but successful period of private practice at Lithgow, N S W , he enlisted in the Australian Imperial Force in May, 1916, and went to France in November He had already held a commission in the Scottish Rifles, C M F , and was soon transferred to the Australian Army Medical Corps He won the Military Cross by attention to wounded close to an ammunition dump in which shells were constantly exploding, and by his disregard of personal danger was instrumental in saving many lives

Major Kirkland was a keen sportsman at school and college which he represented in athletics His friends feel the loss of one who was universally recognised as a pleasant companion and a capable and conscientious officer He was unmarried

JAMES ERNEST STUDHOLME WILSON, M R C S Eng ,

MILITARY CROSS

CAPTAIN ROYAL ARMY MEDICAL CORPS

Captain J E S Wilson, who died of wounds on August 23rd at the age of 31 years, was elder son of the late Rev Studholme Wilson, for many years rector of Millbrook, Southampton, and Mrs Wilson, of Stoneleigh, Newport, Salop He was educated at Summerfields, near Oxford, and at Radley, took his medical course at the London Hospital, obtaining the Conjoint qualifications in 1911, and starting at once in general practice at Iver, Bucks

In December, 1915, he obtained a commission in the Royal Army Medical Corps, attached to a Bucks regiment, and left with his battalion in the following May Two months later he was awarded the Military Cross 'for conspicuous gallantry and devotion to duty during operations," after having gone through a very heavy barrage to assist the wounded His colonel writes of Captain Wilson's courage "He was himself hit early in the evening but insisted on going on with his work for six hours His name" he adds, 'will be a lasting and inspiring memory to the officers and men of his battalion "

Captain Wilson married in 1912 Marjory, daughter of the late Thomas Ireland, of Mossley Hill, Liverpool, who survives him with an only child

RONALD LENNOX HENDERSON, M B , Ch.B Edin ,

MILITARY CROSS

CAPTAIN AUSTRALIAN ARMY MEDICAL CORPS

Captain R L Henderson, who died of wounds received in action at Bullecourt in May this year, graduated at Edinburgh University in 1903 before emigrating to New South Wales, where he practised for several years at Lismore In July, 1915, he joined the Australian Army Medical Corps and was sent to Egypt afterwards being attached for several months to No 2 Stationary Hospital at Lemnos When the Australian troops left for France he went with them and remained, except for a few months' illness, until the time of his fatal injury He was hit in the leg in June, 1916, but refused to be evacuated, and tended the wounded of his unit with no thought of personal safety A few days before being wounded himself he was awarded the Military Cross His superior officer writes of him "Always a splendid companion in times of stress, his kindly humour and steadfast devotion to duty made him a favourite with his fellow officers and his men We have lost in him a man of exceptional courage and high character "

ANTHONY TRAILL, M B , Ch B Oxon ,

CAPTAIN ROYAL ARMY MEDICAL CORPS

Captain A. Traill, who died at a casualty clearing station in France on August 25th, after a few days' illness, was 27 years of age and second son of Edmund B Traill, of Pebmarsh, Essex, and Chirú Traill Argentina He was born near Dublin, and educated at Charterhouse and New College, Oxford While at Oxford he became president of the O U L T C and. won the challenge cup From Oxford he went to Guy's Hospital, obtaining his medical degrees in 1915 In February, 1916 he received a commission in the Royal Army Medical Corps, and went to the front in the early part of this year While still at Oxford he had a severe attack of hæmorrhage from a duodenal ulcer and it was a recurrence of this trouble while attached to a regiment which was the cause of his untimely death. A promising career has been thus cut short

EDMUND FITZGERALD BANNATYNE WILSON,

M D Dub ,

MAJOR SOUTH AFRICAN MEDICAL CORPS

Major E F B Wilson, who died as the result of an accident on August 17th, was educated at Trinity College, Dublin, taking the M B , B Ch in 1881 and the M D in 1890 After practising for a few years in Ireland he went to South Africa, settling in Harrismith, Orange Free State At the outbreak of the Boer War he was still in practice in this town, but managed to escape, and eventually was given a commission as a combatant in one of the Irregular Corps which were formed This he held for a short time, when the need for doctors becoming acute he was utilised as a medical officer He received the Queen's and King's medals for the campaign, and after the war returned to Harrismith when he was appointed district surgeon and railway medical officer under the British régime In this capacity he did much useful work, and was greatly esteemed in the town and district

At the outbreak of the present world war Major Wilson joined up for service with the Union Forces, and after suppression of the rebellion he was sent to German South West Africa At the conclusion of the campaign he joined the South African Overseas Expeditionary Force with the rank of major in the 1st South African General Hospital and after some service with that unit in England proceeded with it to France Although nearly 60 years of age, Major Wilson was of too energetic a temperament to remain with a general hospital, and after serving with the unit for a short period he effected an exchange so as to be attached to the South African Heavy Artillery, and he also did short spells of duty with the cavalry and South African Field Ambulance He died as a result of a fall from his horse Major Wilson leaves a widow and several children, one of whom is serving overseas in the Royal Flying Corps

W R ASPINALL, M B, CH.M. SYD,

MILITARY CROSS

CAPTAIN AUSTRALIAN ARMY MEDICAL CORPS

Captain W R Aspinall who was killed on active service last July at the age of 25 years, was youngest son of the Rev A. Aspinall, M A., of Sydney, N S W He was educated at the Scots College, and from there passed to Sydney University Here he showed a keen interest in all branches of athletics, and won his football 'Blue" in his second year He was captain of the team when war broke out and the same year played for New South Wales He also took a leading position in the social life of the University, and was elected Vice President of the Union Graduating M B Ch M with honours in September, 1915, he was appointed house surgeon at Sydney Hospital

Early in 1916 he joined up and served some time in Egypt before being invalided to England with pneumonia He went to France later in the year, and after serving some months with a field ambulance on the Somme, was attached to a field artillery brigade After several months of consistently fine work he was awarded the Military Cross for conspicuous gallantry under most trying circumstances During a serious attack he worked all day under heavy machine gun and shell fire without cover, tending friend and foe alike with absolute disregard for his own safety He was killed at his guns In the trenches as in other walks of life he set a standard of personal courage and cheerfulness under all conditions that gained him universal respect

---

ARMY MEDICAL TRAINING IN AMERICA —A correspondent writes from the Medical Officers' Training Camp, Fort Benjamin Harrison Indiana "We are getting a great amount of thorough instruction The ground is gone over rapidly possibly because of the shortness of time allowable before our services are needed The men are buckling down, and almost without exception are earnest and patriotic in their work It is a remarkable thing to see popular and successful physicians and surgeons giving up fine incomes and living in this great army training camp and putting up cheerfully with its lack of conveniences There are some 1200 M D s here now besides line officers all getting ready to go out to care for and train the hundred thousands of our new draft army "

THE NATIONAL WAR AIMS COMMITTEE S LEAFLETS —The National War Aims Committee has issued a series of leaflets of a very opportune sort The first 15 are (1) Prime Minister s Speech, (2) Interview with General Sir W Robertson, (3) What Are We Fighting For' (4) There Must Be No Next Time', (5) Winning the War, (6) The Nation Made War and the Nation Must Make the Peace, (7) The Truth About the War, (8) Labour and the War (9) President Wilson on Peace Terms and War Aims (10) The Kaiser Manner, (11) The Greatest and the Last Crusade' (12) Gentlemen' of Germany, (13) Peace at Germany s Price (14) Right and Might a Lesson which Germany Must be Made to Unlearn (15) A Kalendar of Kultur Of these No 10 The Kaiser Manner consisting of only one leaf is perhaps the one which will attract most attention as most of the other speeches have been read in the daily newspapers more than once The reverse of this leaf contains a reproduction by the special permission of the proprietors of *Punch* of a drawing by Bernard Partridge entitled the Knightly Manner and depicts the Kaiser in armour standing over the prostrate body of the female personification of Belgium who says 'As long as there is motion in my body and life to give me words I'll cry for Justice to which the Kaiser replies 'Justice shall never hear you I am Justice This is explained parenthetically by a reminder as follows (There is no longer any international law —The Kaiser to Mr Gerard) This powerful picture will entice the observer into a reverie of right and wrong, and truth and fiction It is founded on a passage in Beaumont and Fletcher

Correspondence.

"Audi alteram partem "

A STATE-AIDED MIDWIFERY SERVICE

To the Editor of THE LANCET

SIR,—The time has arrived when the question of the midwifery service of the country merits consideration The Act of 1902 was mainly the work of 'those who claim that they are generally considered to be most competent to advise on such a subject"—namely the Fellows of the Royal College of Physicians of London The very large majority of the medical profession were, and are, only too well aware that the subject is in the main one of economics, and can never be settled by the establishment of a State controlled body of nurses

The result of legislation has been that districts which cannot support a midwife have remained unprovided for, although a bulky tome is annually issued which contains the names of thousands of women who are licensed to practise Improvement can only be obtained by a process of decentralisation The money which is now spent upon the operations of the Midwives Board should be devoted to work carried on by sanitary authorities and that Board should be abolished Sanitary authorities have now organisations for carrying on the work and are quite competent to decide upon the fitness of the women they employ, and they should be subsidised out of the money saved by the extinction of the Midwives Board.

The attempt to make a new class of midwifery practitioners has failed, and if the establishment of such a class is desired a sufficiently equipped class must be made and the subject of midwifery removed from the compulsory subjects of medical students At the present time midwives do not occupy a position which is quite fair to them They are not considered to be competent to carry out their work without the aid of stringent rules and regulations They consequently have no responsibility so long as these rules are obeyed Some are incompetent and others competent and no rules will make those competent who are incompetent If a sufficient class must be obtained it must be a class who are so competent that their work can be carried on without rules and regulations The repeal of the Act of 1902 is urgently required

I am, Sir, yours faithfully,

LOVELL DRAGE.

Hatfield Oct 1st 1917

*** Dr Lovell Drage attributes much to Fellows of the Royal College of Physicians of London The General Medical Council, after deliberations in which the representatives of all the medical faculties and corporations took part suggested many changes in legislation in the Bill which later became law The question to which he alludes has already become urgent and we publish this week notes on the course taken in St Pancras and at Chelmsford —ED L

SACRO-ILIAC STRAIN

To the Editor of THE LANCET

SIR —I beg permission to contribute a few observations on the annotation in your issue of Sept. 29th on the above named condition It is true indeed "a lesion which the general practitioner often sees but fails to recognise but whether this is 'because it has been described only in recent years mainly by American orthopædic surgeons' is open to question A much more potent reason is that it has not been accepted as a clinical entity by English surgeons at all When I read a paper[1] on the subject with numerous references to the literature and notes of nine cases before the Orthopædic Section of the Royal Society of Medicine in 1913 it was greeted with buckets of cold water the President cynically remarking that in all his experience he had never been fortunate enough to meet with a single case and when I have tried to interest others in this condition I have been received with looks of blank incredulity The condition of course undoubtedly exists and the medical profession should be most grateful to you for making it known Its dominant feature, however is not pain over the sacro-iliac point in front, but pain over the sacro iliac joint behind I have seen many cases now, but never one in which this sign was absent

---

[1] See Transactions of the Royal Society of Medicine vol

As regards treatment, does not your annotation present altogether too rosy a view? "Treatment is simple and gives most satisfactory results" I have found treatment most difficult and disappointing, having only been able to cure completely two cases The keynote of the treatment is to compress the two halves of the pelvis together, but in actual practice this is not easy Encircling strips of plaster applied tightly cause sores at their edges after one or two days, and have to be left off while the sores heal, belts have all proved unsatisfactory while manipulation under an anæsthetic relieves for a time, only to be followed by a recurrence of the trouble The best apparatus has proved to be an ordinary corset with reinforcing webbing bands around the pelvis

Finally, as to nomenclature For reasons I do not propose to enter into here, there are many objections to the term "sacro iliac *strain*" These are all got over by describing the condition as "*painful* sacro iliac joint"

I am, Sir, yours faithfully,
PAUL BERNARD ROTH
Harley street, W, Sept 29th 1917

A WAR MEMORIAL TO OLD EPSOMIANS

To the Editor of THE LANCET

SIR,—Two informal meetings of old Epsomians have been held regarding the question of raising a memorial to old Epsom boys who have fought and fallen in this war It was decided that a meeting should be held at the offices of the College, 37, Soho-square, London, W, at 4 P M, on Friday Oct 12th It is hoped to get an expression of opinion at that meeting as to whether such a memorial should be raised, how it should be raised, and what form such a memorial should take A treasurer and secretaries for this memorial fund will be appointed The Rev W Barton, the headmaster of the school, and myself are acting as secretaries until the regular appointments are made As addresses are so uncertain it has seemed desirable to notify old Epsom boys of this meeting through the newspapers Will all who can come to the meeting and will those who cannot come express their views in a letter addressed to me?

I am, Sir, yours faithfully,
EDRED M CORNER
7 Harley-street, London, W 1 Sept. 28th 1917

A CASE OF PERIODIC ATTACKS OF PYREXIA

To the Editor of THE LANCET

SIR,—The case recorded by Dr R V Solly under the above heading in your issue of Sept 8th (p 386) has considerable resemblance to one of rat-bite fever The regular pyrexial attacks with high temperature and "well" intervals, the erythematous eruption, the cessation of the disease after the administration of galyl, and the seven weeks' duration before the pyrexial attacks began to become irregular, all coincide closely with the course of a case of rat-bite fever

I am, Sir yours faithfully
R TANNER HEWLETT, M D Lond
Chandos-street, W C Sept 24th 1917

"RECONSTRUCTION"

To the Editor of THE LANCET

SIR,—I have read with great pleasure the leading article entitled "Reconstruction" in your issue of Sept. 15th and warmly welcome the suggestion of the formation of a board such as you put forward to consider and interpret facts relating to professional reconstruction after the war Since the outbreak of war there has been a tendency on the part of certain of those remaining at home to try to create a new Heaven and new earth, in the absence of their betters with themselves as archangels This tendency has resulted in a complete revolution of our political electorate, and now threatens an equally drastic change in our professional status Apart from the impertinence, which surely is sometimes evident, it is also an injustice During the last two years I have been in many parts of the world and I can only say that amongst the hundreds of medical officers that I have met there exists a real mistrust as to our future status—a general feeling that our interests are being neglected and that our future is being decided overmuch by the "indispensables" and the "embusquers," who suffer from glib tongues and lately from overweighted pockets I hope that others will give you their views on the matter, especially those connected with medical units serving abroad

I am, Sir, yours faithfully,
A HURRELL STYLE, M A M D Cantab,
Temporary Captain R A M C
Royal Societies Club St James's street, S W Sept 28th 1917

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL. —The two Goldsmid Entrance Exhibitions, offered annually for competition in September were awarded this year to Mr H L Heimann and Mr V R Khanolkar, both of University College, London

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY —A course of lectures on Tropical Hygiene will be given by Mr H. G Plimmer, F R S, professor of comparative pathology, in the lecture room of the Botany Department of the College, Prince Consort road, South Kensington, London, S.W, on Tuesdays from 4–5 P M, during the first half of the session 1917–18, beginning on Oct 9th The course is intended for officers in H M Forces who are likely to be sent to hot countries, and will deal with infectious diseases, their causation and prevention, advice as to the maintenance of health in tropics, and the treatment of minor complaints and injuries. The fee for the course is £1 Application to the Registrar of the Imperial College

Notes, Short Comments, and Answers to Correspondents.

GILBERT AND ELLICE ISLANDS

A REPORT recently presented to Parliament on these two groups of islands in the Pacific—formerly constituting a Protectorate, but formally annexed to the Empire in 1915 —contains some interesting references to the health and medical administration of the territory The Gilbert group, situated between 4° N and 3° S latitude and 172° and 177° W longitude, consists of 16 islands, with several smaller islands or islets depending upon them, and the Ellice group between 5° S and 10½° S latitude and 176° E and 179 58° W longitude, consists of nine islands (in which Ocean Island, or Paanopa, is included) The total area of the two groups is only 180 square miles, and the population, according to the Census of 1911, comprised 30 523 natives, 301 Asiatics, and 297 Europeans The births recorded in 1915–16 totalled 959 and the deaths 726

In the Gilbert Islands a serious epidemic of influenza carried off many old people and weaklings in 1914–15 but the figures for 1913–14 and 1915–16 were most satisfactory in view of the fact that for many years previously the population of the islands was decreasing to such an extent that it was predicted that the race would soon be exterminated owing to contact with civilisation It is true that the white man introduced syphilis and was probably responsible for the scourge of tuberculosis but medical science is using every effort to restore the balance and to bring relief and improved health to these simple and kindly folk During the past three years the expenditure on the medical department has been very largely increased There was a time when sickness was hidden and when medical inspection visits were feared In 1913–14 a determined effort was first made to put the medical department on a sound footing It was realised that this result could not be achieved by the importation of medical skill only; it was essential to catch and to hold the interest and confidence of their own people to demonstrate that the power to alleviate and to heal could be learnt by their kith and kin and that operations were *not* hazardous miracles to be performed in secret under the white man s spell It is already evident from statistics that some measure of success is being attained In spite of the difficulty of transport due to the need of a Government vessel and to the curtailment of the trading steamer service in war-time the number of cases admitted into the hospitals and the operations performed are proof that these people have realised what medical attention can do for them

The results of the treatment of yaws by salvarsan or by its equivalent galyl or kharsivan confirm the reports from the West Indies and elsewhere The native name given to this drug is Te Iti" or lightning from the marvellous rapidity of the cure Satisfactory results have also been obtained by the use of this drug in cases of syphilis which is prevalent still in the groups this however is naturally a slower process especially in its advanced stages It is, unfortunately still difficult to get the patient to realise the gravity of this disease in the early stages The need for a plentiful supply of galyl or kharsivan cannot be too earnestly insisted on In cases of elephantiasis prevalent in several of the islands kharsivan has also been used with good results

The treatment of tuberculosis the greatest scourge of the colony is a matter which calls for the patience and perseverance of those on the spot Tuberculin may be used in surgical cases but the various precautionary measures do not appeal to the careless easy going native Tuberculosis is believed to have been originated amongst these people by the wearing of European dress which led to the discontinuance of the practice of oiling the bodies which was formerly done as soon as the cold westerly winds set in with heavy rains Though efforts have been made to persuade the natives to revert to their native dress and to the lubrication of the body it is feared that the attempt has been made too late It is natural that the traders are averse to this since probably 50 per cent of the money which they pay out for produce comes back to them from the sale of tropical clothing to natives The missions al o have shown no wish to help this movement Shirts and trousers for men and the long sweeping garment for women are the outward signs of Christianity It is practically only among pagans and in the Government gaols that the sensible native dress may now be seen

The headquarters of the medical staff are at Tarawa with branch European run hospitals at Tabiteauea in the Central Gilberts and at Funafuti in the Ellice group The institution of a training school for native medical students at Tarawa has proved a great boon to the colony The natives have come forward readily for instruction and every island is now in charge of a medical dresser of fair experience As opportunities of relief offer these dressers return to the Central Hospital for a further period of instruction and the standard of efficiency is gradually raised throughout the native hospital During the year 1175 cases were admitted to the Tarawa Central Hospital and 619 operations were performed At the Funafuti hospital 535 cases were admitted and 180 operations performed Since November 1915 the European medical staff has again been reduced to one this officer is however ably assisted by two native medical practitioners to one of whom (Sowani) the colony is indebted for many years of most faithful and efficient service The services of a white matron have now been acquired for the Tarawa hospital and a scheme for the training of half-caste girls as maternity nurses has been started During the year a white ward for the treatment of European patients has been opened and has already proved useful

The erection and equipment of a leper asylum upon an isolated islet awaits acquisition of a Government vessel for the collection of cases Each island is at present equipped with its own asylum but there is always danger of contact or intercourse and this scourge cannot be wiped out until a central isolated asylum can be constructed and maintained with the assistance of a Government vessel

THE SUPER HEN

To the Editor of THE LANCET

SIR,—Amongst some eggs which I bought last week there was one which was rather large, and which I voted was the progeny of a goose and included in my purchase by mistake On cracking it it yielded two fine yelks I used to look after a number of hens for several years and collect their eggs and cook a good many, but although I have seen some curious specimens of twisted and fantastic shaped shells, and of shell less eggs, I have not met with one before having two yelks

I have had the curiosity since to look for information in your columns In THE LANCET of Sept 26th, 1885 there is an account of a hen's egg with two shells one inside the other, and in the issue of Dec 5th, 1885, a letter describes an egg with two shells, each shell when broken yielding yelk and white, and in that of Oct 17th, 1885, a correspondent wrote that his medical partner had a similar egg and requested Professor Huxley's opinion on it "It is very simple," said Huxley, "reversed peristaltic action takes place in the oviduct after the shell is formed, the egg is driven back, and when again descending gets a coating of yelk, albumen, and shell" But I do not see any record of a double yelk mentioned —I am, Sir, yours faithfully,

Oct 3rd 1917 A READER

A CORRECTION

To the Editor of THE LANCET

SIR,—May I correct a statement in your reviewer's extremely considerate remarks upon the last edition of my little book on anæsthetics? Anoci-association is not omitted, as he states, but is briefly described in the pages headed "Nitrous Oxide and Oxygen in Major Surgery" But the word does not occur in the index

I am, Sir, yours faithfully

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention should be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, *and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification*

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor"

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager"

We cannot undertake to return MSS not used.

Offices 423, STRAND, LONDON, W C 2

MANAGER'S NOTICES.

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W C 2, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do *not* reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c, should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

THE COLONIAL AND FOREIGN EDITION is published in time to catch the weekly Friday mails to all parts of the world

TO COLONIAL AND FOREIGN SUBSCRIBERS.

Subscribers abroad are particularly requested to note the rates of subscriptions given on page 4

The Manager will be pleased to forward copies direct from the Offices to places abroad at the rates shown, whatever be the weight of any of the copies so supplied

Valentine's Meat-Juice

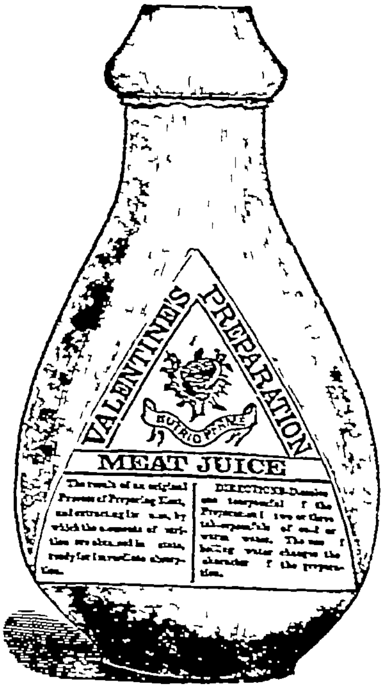
In **Typhoid, Gastric** and **Other Fevers** where it is **Essential** to **Sustain** the **Patient** without Irritating the **Weakened Digestive Organs, Valentine's Meat-Juice** demonstrates its **Ease** of **Assimilation** and **Power** of **Sustaining** and **Strengthening** when **Other Food Fails.**

Fever Cases

S. R Nissley, M.D., *Elizabethtown, Pa, U S A*
"In the recent epidemic of Typhoid Fever that prevailed in this locality, I had an excellent opportunity of testing the nutritious elements of Valentine's Meat-Juice In one particular case where there was stiffness in the jaws rendering deglutition difficult, from the onslaught of the malady, I sustained life by the administration of Valentine's Meat Juice beyond a fortnight In all cases where I used the Meat-Juice, it surpassed my most sanguine expectations, and I may add that the elegance of the preparation is vastly enhanced by the retention of the original bovine flavor of the beef It is the best preparation of meat that I have used in my practice, and I have no hesitation in saying that it is borne with impunity by the most delicate stomach and will be found to be an invaluable adjunct to the list of our therapeutic agents"

Dr. Gervasio de Gobeo, *Physician to the Asylum, Bilbao, Spain* "I have tried Valentine's Meat-Juice on two patients convalescing from Typhoid Fever They were in a most exhausted condition, owing to the fact that their digestive organs would admit no other class of nourishment excepting milk. I ordered and gave them Valentine's Meat-Juice, which their stomachs retained perfectly, and they immediately commenced regaining their strength."

J. R. Wood, M.D, *Physician, Sheltering Arms Hospital, Paint Creek, W Va, U S A* "I have been using Valentine's Meat-Juice in the treatment of Typhoid Fever cases in the Sheltering Arms Hospital, for the last two or three weeks, with the most gratifying results both to the patient and physician. I consider it the best preparation of animal food I have ever seen, in fact, the only one I have ever had any success with"



For Sale by European and American Chemists and Druggists.

Report
UPON
AN INVESTIGATION INTO THE EFFECTS OF COLD UPON THE BODY *

BY NORMAN C LAKE, M D M S, D Sc LOND, F R C S ENG,
ASSISTANT SURGEON QUEEN'S HOSPITAL FOR CHILDREN
TEMPORARY CAPTAIN R.A.M.C

DURING investigations into the growth of tissues *in vitro* upon the lines of Carrel's[1] well known work it became necessary to investigate the effects of temperature changes In particular the effect of cold upon the tissues was studied, and, as will be seen from the experiments detailed, led to the conclusion that cold down to – 6° C, brought about a state of suspended animation in which for considerable periods the tissue could be preserved intact and its potential vitality maintained at the normal standard This rather heterodox conclusion necessitated a re investigation of frost-bite,' for if the effect of chilling" of the tissues is to produce a state of suspended animation, then it will be illogical to accept theories which assume a direct effect of a degenerative and destructive nature. The term "frost-bite" is here used in its widest sense, and includes such conditions as "trench foot." Later on we shall attempt to separate these into two entities having as their basis different pathological processes

In the more recent of the writings upon the subject the pathology of the condition has been explained in various ways Lorrain Smith Ritchie and Dawson,[2] after a series of very excellent investigations both from the clinical and experimental points of view, came to the conclusion that the pathology of "trench foot' was the same as that of true frost-bite, although of much less intensity and that both are primarily due to the direct effect of cold upon the tissues, although other factors, such as pressure, had a determining effect Many other writers agree with them In several recent articles, written chiefly from the clinical standpoint it has been suggested that vaso-motor disturbances play an important part, these, again, may be divided up into many smaller groups Some explain the effects by assuming a lack of oxygen to the part, others by lack of nutritive plasma, and others again by special effects upon the endothelium of the vessel walls That other factors than cold play a part in the production of ' trench foot" is undoubted but in all probability these factors must be considered as secondary and entirely subsidiary to the temperature variation Rideal and Waller[3] have, for instance, investigated the effects of water and saline solutions upon the feet, but failed in any of their experiments to produce conditions which resembled trench foot' and it is doubtful whether the slight disturbances of sensibility which they produced in any way correspond to the paresthesiæ which occur when the additional factor of cold is brought into play These questions will be dealt with, however, more fully later on

In considering the pathology of frost bite, it is logical at least to say that the effects are either purely local or are reflex with the possible combination of both, and an endeavour has been made to bear this constantly in mind

The details of the work which follow are divided up into five groups of experiments —

1. Investigation into the effects of cold upon the individual tissues when detached from all extraneous influences, whether of the circulatory or nervous system, such tissues may conveniently be called isolated tissues
2. Investigation into the effects of cold upon the blood.
3 Investigation into the effects of cold upon the tissues in normal relationship to the circulatory and nervous systems
4 Investigation into the effects of cold upon the tissues in abnormal relationship to the circulatory and nervous systems
5 Finally the conclusions drawn from these investigations both with regard to pathology and treatment

(1) *Investigation into the Effects of Cold upon the Individual Tissues when Isolated*

The method of growing tissues *in vitro* devised by Burrows[4] and improved by Carrel[5] lends itself very excellently to this work It consists, in brief, of explanting small portions of tissue into media, the chief basis of which is plasma. The portion of tissue used is small and, having been placed on a coverslip, is surrounded by the medium, and when this is coagulated or set the whole is inverted on to a celled slide, sealed with paraffin, and incubated to 37 5° C After a varying number of days the tissue can, if necessary, be transplanted into fresh medium, after washing in Ringer solution, and in this way kept alive and actively growing for an indefinite period If these growths are not transplanted they sooner or later die from the accumulation of products of metabolism in the media The effects of cold may be investigated either by exposing the tissue *en masse* before explantation or by placing the slide with the explanted growing tissue into the required temperature

In all between 500 and 600 experiments have been made in which the tissue has been exposed for some period to a greater or less degree of cold, and the individual experiments quoted here have been repeated several times, in some cases over 100 times, with practically constant results The tissues used were obtained from rabbits, mice, frogs, and in many cases from human beings during operations

Practically every tissue in the body has been explanted, including heart, endothelium, connective tissue, skin, thymus, thyroid, kidney, liver spleen, testicle, ovary, brain, nerve pituitary, bone, mucosa, pancreas, &c The media used included Ringer's solution, Ringer's solution and agar, serum and serum agar, plasma, hypotonic plasma, and plasma with the addition of various glandular and other extracts As far as the effects of cold go, however, the medium appears to make very little difference, and so for the most part hypotonic plasma was used in order to make the growths uniform Homologous plasma was generally used, but occasionally heterologous plasma (e g, rabbit tissue on human plasma, &c)

The criteria of activity in these explants may be divided into two main divisions—namely, growth and function Growth is very easily observed and often exceedingly vigorous, function is much more difficult to test, in the case of the embryo and young adult heart, however, pulsation of the small explanted piece occurs with a fair degree of regularity and forms a delicate and easily observed test of functional activity For this reason the great majority of the growths used for this research were young or embryo heart tissues The staining of the surrounding medium by the excreted bile may be used as a test of activity in the liver growths although this is rather crude, and hence has only been used occasionally The functional activity of other tissues, and particularly of nerve tissues, it is almost impossible to test in these growths, and in this case the exact morphological reproduction of the tissue cells may be fairly logically taken to imply that such tissues are functionally active It may be argued that this jump from vegetative to functional activity is not justified and that the two are quite separate entities Against this is the fact that among hundreds of heart growths it has been observed that there is a close relationship between the two, the more vigorous the growth the more active the pulsation A heart growth pulsating but not growing (functionally but not vegetatively active) was not observed among the whole series

The experiments in this group may be divided up as follows —

(*a*) In which the tissue *en masse* was stored in Ringer's solution at low temperatures Portions of the tissue were then explanted and incubated

(1) Stored at temperature of + 2° C (in ice chest) for 48 hours and then cultured In practically all these cases growth rather more vigorous than that in the controls which were immediately explanted took place

Typical example —March 2nd 1916 Rabbit embryo (14 days) placed in Ringer and stored at + 2° C March 4th Portion of heart explanted into medium of rabbit plasma (No 445) March 6th Vigorous pulsation and extensive growth—transplanted March 7th: Pulsation continues fresh growth actively occurring

(2) Stored at temperature of + 2° C for 7 days and then cultured May 31st Rabbit embryo (10 days) placed in Ringer and stored at + 2° C June 6th Skin explanted into medium of hypotonic rabbit plasma (No 974) June 8th Extensive growth of fibroblastic and epithelial cells

(3) Stored at temperature of –10° C for 30 minutes and then cultured (May 13th) in hypotonic plasma (859) May 17th: No growth observed

From this series of experiments the conclusion may be drawn that tissues may be stored at a temperature of – 2° C for periods up to at least 7 days without losing any of their vitality either functional or vegetative and, indeed in some cases appear to have increased in vitality over the controls which were explanted immediately At the same time, temperatures as low as −10° C kill the tissues within 30 minutes

---

* Research conducted under a grant from the Medical Research Committee at the Pathological Laboratories, Charing Cross Hospital Medical School Thesis accepted for the degree of D Sc Lond

(*b*) Actively growing tissue in explants exposed to varying degree of cold for certain periods of time and then incubated again

(1) Stored at temperature of +2° C

March 9th: Small portion of fresh human thyroid (removed at operation) explanted into human plasma. March 10th: Some liquefaction of medium had occurred placed in ice chest for 24 hours and again incubated March 13th Fairly extensive growth of epithelial cells

(Liquefaction is common in human growths and there is usually over 24 hours latent period before growth starts)

(2) Stored at temperature of +2° C for 16 days

April 24th Rabbit embryo heart stored at +2° C in Ringer for 24 hours then explanted in hypotonic plasma. April 26th Active growth and pulsation Placed in ice chest for 16 days incubated again within 2 hours vigorous pulsation was occurring and later active new growth was noted which continued for several transplants

(3) Stored at temperature of −5° C for 30 minutes

April 24th: Rabbit embryo heart stored at +2° C in Ringer for 24 hours then explanted into hypotonic rabbit plasma April 26th: Vigorous pulsation and extensive growth kept on ice and salt at −5° C for 30 minutes Incubated again As soon as temperature reached +30° C pulsation started and growth went on in further *transplants for several generations.*

(4) Stored at temperature of −7° C for 30 minutes

May 5th Rabbit embryo heart stored at +2° C in Ringer for 24 hours then explanted into hypotonic plasma May 7th: Vigorous pulsation and active growth. Placed on ice and salt at −7° C for *30 minutes the plasma froze into an opaque solid material at this temperature* On incubating the fibrin net-work was completely broken up and the medium liquefied the new grown cells were expanded into circular form much vacuolated and rapidly broke up altogether Pulsation stopped and although the tissue was transplanted several times no further growth or pulsation occurred

This experiment repeated with temperatures down to −18° C gave the same result.

It is necessary here to interpose some further observations upon this last series of experiments We have already drawn attention to the fact that these growths, *if not transplanted*, eventually die of toxæmia from accumulation of metabolic products The onset of this condition can be readily observed In the first place, the growth becomes much slower and pulsation less active, in the second place, the newly grown cells become circular and much vacuolated In these particular experiments the controls began to exhibit this condition in about five days and transplantation became necessary It will be noted that in the chilled specimens growth had already been occurring for two days *before they* were placed in the ice chest, and upon re incubating special care was taken to look for the onset of vacuolation in the cells Contrary to expectation, this did not occur on the third day, but on the fifth or sixth day The explanation is probably that the metabolic products had diffused during the condition of suspended animation from the immediate proximity of the growth and so had become diluted The further significance of this observation will be noted later

FIG 1

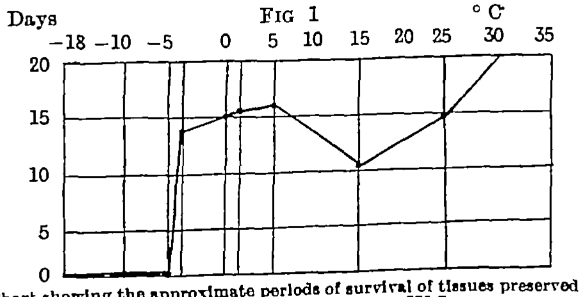

Chart showing the approximate periods of survival of tissues preserved at temperatures between −18° C and +37° C

FIG 2

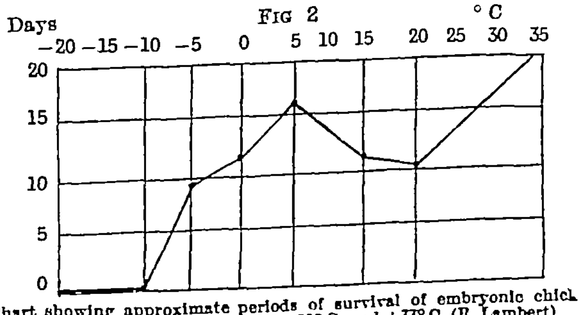

Chart showing approximate periods of survival of embryonic chick tissues at temperatures between −20° C and +33° C (R Lambert)

In this first series of experiments upon isolated tissues results were obtained which may be represented graphically (Fig 1) The curve has been charted from the general results obtained upon rabbit tissues and does not pretend to any very great accuracy Its general form is, however correct, and it agrees so closely to the curve given by R Lambert[9] for chick and rat tissues that it may be taken as approximating to accuracy (Fig 2) The main characteristics of both these curves are the sudden drop in the region of − 6° C and the dip in the curve at +14°–16° C The deductions to be drawn from these curves will appear in the last section

(2) *Effects of Cold upon the Blood*

In Da Costa's "Surgery," in the section on Frost-bite, appears the statement that definite changes occur in the blood in the nature of cellular degenerations, &c

It remains to be seen whether the changes occurring in isolated blood *in vitro* corresponded to those occurring in the other tissues of the body If the cellular contents of the blood became injured by the cold we should expect two results (1) The breaking up of the white cells would liberate tissue ferment and so bring about coagulation, (2) the red blood cells would hæmolyse

For the most part human blood was used for these experiments, as it was found to be difficult to keep rabbit's blood longer than 12 hours without coagulation occurring As far as rabbit's blood was investigated, however, it agreed entirely with the results given below for human blood It was aseptically drawn off from the superficial veins of the arm through a very large (⅛ in bore) needle evenly coated with paraffin From this it flowed into paraffined test-tubes contained in a special ice chest, the temperature of which averaged +2° C These tubes were sealed with paraffined corks

(1) Blood collected quickly in this manner and stored at +2° C can be kept between three and four days without coagulating If at the end of three days the plasma and corpuscles be mixed by shaking, and the whole centrifuged the supernatant plasma is practically unchanged in colour, a few specimens showing the slightest darkening of the straw tint which probably indicated hæmolysis Even at the end of four days coagulation at this temperature is slow and imperfect, for if the exuded fluid, which is apparently serum, be warmed to +30° C and a little tissue extract added coagulation again occurs and a fairly firm clot is formed.

(2) Three specimens of the same blood were collected in three well paraffined tubes—A, B, and C

A. Immersed in melting ice at temperature 0° C for 30 minutes then kept at +10° C for 5 minutes At the end of this time the blood was quite fluid and slight separation of plasma had occurred. Centrifuged 3½ minutes Excellent separation of perfectly clear plasma Plasma and corpuscles were again mixed and centrifuged Again there was excellent separation of clear plasma.

B Immersed in ice and salt at temperature −5° C for 30 minutes then kept at +10° C for 5 minutes. The blood remained uncoagulated and was centrifuged 3½ minutes Excellent separation of clear straw plasma Plasma and corpuscles mixed and centrifuged The supernatant plasma still remained absolutely clear

C Immersed in ice and salt temperature −9° C for 30 minutes The blood became thick and gelatinous. Upon warming to +10° C for 5 minutes the blood coagulated and on centrifuging no separation occurred The clot was well broken up and the whole again centrifuged The supernatant serum was stained very dark red so that it was difficult to distinguish any line of separation

(3) Three specimens of the same blood in three tubes D, E F, were kept at +2° C for 1½ hours At the end of this time all were uncoagulated and the blood freely mobile

D Immersed in melting ice at 0° C for 1½ hours. Partial separation of plasma occurred Centrifuged 3½ minutes Good separation of clear plasma Mixed and centrifuged again for 2 minutes Plasma again clear Warmed to coagulate and kept at room temperature 17° C for 1 hour Clot broken up and the whole again centrifuged supernatant serum absolutely clear

E Immersed in ice and salt for 1½ hours The temperature at start was −5° C and slowly rose during the immersion to −1° C Partial separation of plasma by gravity Centrifuged 3½ minutes Good separation of absolutely clear plasma. Mixed and centrifuged again plasma still clear Warmed to coagulate and kept at room temperature for 1 hour Clot broken up and the whole again centrifuged serum absolutely clear

F Immersed in ice and salt temperature −12° C rising to −7° C during course of experiments (1½ hours) Whole solid no separation of plasma by gravity Centrifuged 3½ minutes no separation the whole having clotted Clot broken up centrifuged again. Serum dark red difficult to see line of separation. Warmed and kept at room temperature for 1 hour Mixed and again centrifuged Serum so red as to be almost opaque to transmitted light

The conclusions to be drawn from this second group of experiments may be represented by the curves plotted in Figs 3 and 4 The first point of importance to be noted in regarding these curves is the close similarity between Fig 3 and Fig 1, and from it the conclusion may be drawn that the effect of cold upon the actual blood cells, both white and red, is precisely the same as its effect upon isolated tissue cells The explanation of the curve in Fig 4 is not quite so obvious It must be remembered, however, that, among other things, the presence of tissue extracts containing thrombokinase is essential for the coagulation of the blood In the case of blood kept at the body temperature the leucocytes, and perhaps the platelets are in a state of normal activity, and during their metabolism throw off products containing the necessary thrombokinase As we have already shown, the tissue and blood cells at temperatures in the region of zero are in a state of suspended animation All metabolic processes are therefore inhibited hence coagulation only occurs after prolonged periods and then very imperfectly On the other hand, as soon as temperatures below −6° C are reached there is actual physical destruction of the cells liberating the necessary thrombokinase The blood at this temperature is already frozen (solid) but as soon as the temperature rises clotting must occur This we consider is a logical explanation of the phenomena recorded in the above paragraphs and it agrees entirely with the deductions drawn from the first paragraph As a result we must regard temperatures in the region of −6° C (the exact temperature varies a little with different tissues) as being critical in nature as far as the function and activity of both tissues and blood cells go

FIG 3

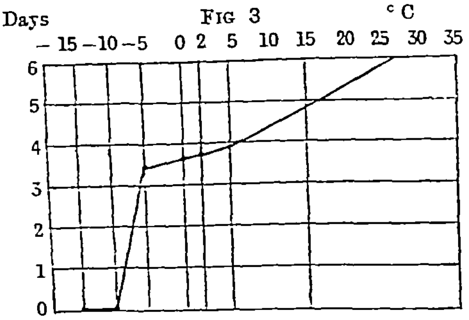

Chart showing the degree of cellular destruction in the blood at varying temperatures The dotted portion of the chart is not the result of actual experiment but is the suggested form derived by analogy from Fig 1

FIG 4

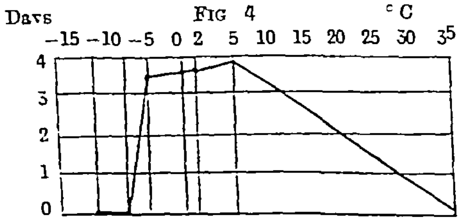

Chart showing roughly the coagulation time in relationship to varying degrees of temperature.

(3) *Investigation of the Effects of Cold upon the Tissues in Normal Relationship to the Circulatory and Nervous Systems*

In this branch a considerable amount of work has already been published. In perusing the literature the first thing that strikes one is the difficulty that all experimenters have experienced in producing any signs of frost-bite unless temperatures below the freezing point of the tissues (that is −6° C) were used In the recent experiments, already quoted by Lorrain Smith Ritchie, and Dawson after exposure of rabbit s feet to temperatures just below zero for three days on end, only the slightest reactionary swelling was produced and in order to produce anything like marked swelling it was usually necessary for these observers to apply constricting bands to the legs

In our own case the experiments were carried out upon rabbits and human skin For the latter series I have to express my deep thanks to the numerous students at Charing Cross Hospital who so readily offered themselves for these investigations

Experiments upon Rabbits

A.—Rabbit anæsthetised left ear immersed in melting ice for 10 minutes and allowed to warm at room temperature Ear slightly blue no swelling 24 hours both ears normal 48 hours both ears normal

B —Rabbit anæsthetised left ear immersed in ice and salt, temperature −3° C for 10 minutes and immediately transferred to water at + 40° C for 15 minutes Ear slightly more congested than control no swelling

C —Rabbit anæsthetised left ear immersed in ice and salt, temperature − 5° C for 3 minutes then transferred to water at + 45° C for 2 minutes This process was repeated four times in succession 1 hour slight increased vascularity of ear no swelling 24 hours, ears perfectly normal

D —Rabbit anæsthetised ear immersed in ice and salt, temperature −10° C for five minutes and then exposed to room temperature 1 hour slight swelling present 12 hours very extensive swelling some blistering

E —Rabbit anæsthetised ear immersed in ice and salt temperature − 4° C for 20 minutes then transferred to water at +39° C

Special attention was paid to the state of the vessels While chilled certain medium sized vessels apparently from their bright red colour arteries stood out very well and the whole appearance of the ear by transmitted light was a healthy pink Upon warming these vessels rapidly diminished in size and practically disappeared only to be replaced by a very large series of vessels, dark blue in colour which were obviously veins By transmitted light the ear became very blue and congested 2 hours slight congestion remained no swelling 12 hours ear absolutely normal

This series of experiments was repeated upon rabbit s feet and gave precisely similar results

Experiments upon Human Skin

F —N C L May 15th Two areas on skin of forearm were used One a small area ½ in in diameter was exposed to CO_2 snow for 35 seconds The second larger area was exposed to ice and salt temperature −5° C to −3° C in a larger container for 20 minutes In both cases the arm was transferred immediately to water at + 40° C Within 10 minutes the first area was blistered showing that the exudation had been enormous The second area was rather red but otherwise normal 12 hours blister has increased in size The second area now normal Under cover of the blister a slough formed which separated after 14 days leaving behind a well marked depressed scar

G —W J C June 5th Two areas on forearm The freezing mixture was applied in a tall glass cylinder and had to be considerably lower than the actual temperature required owing to the enormous amount of heat conveyed to the area from the underlying tissues First area Temperature of mixture −12° C to −10° C Time 12 minutes Then immersed in water at + 40° C The skin did not solidify Second area temperature of mixture −18° C to −16° C Time 12 minutes Then immersed in water at +40° C The skin solidified

In the first area, other than slight temporary hyperæmia no effects were produced In the second area there was immediate swelling of the skin and subcutaneous tissues the effects of which lasted for several days, and although the actual destruction was not enough to cause sloughing yet the overlying skin underwent atrophy and has left behind a slightly depressed smooth area

This experiment was repeated several times upon different students and always produced the same result—namely that unless the skin solidified (that is reached −6° C) no effect other than transient hyperæmia was produced but the slightest degree of solidification produced swelling

As a result then, of this third series of experiments we draw the conclusion that − 6° C is not only critical in regard to isolated tissues, but also with regard to tissues in normal relationship to the body At the same time the transient hyperæmia which invariably occurs in temperatures above −6° C must not be overlooked, for, as will be seen later, it is of the utmost importance in the elucidation of the effects of "chilling" as opposed to true frost-bite

(4) *Investigation into the Effects of Cold upon the Tissues in Abnormal Relationship to the Circulatory and Nervous Systems*

In the last three groups of experiments we have indicated that below − 6° C there is actual destruction of tissue, and so in tissues in normal relationship with the body, swelling and other signs of frost-bite were easily produced when this temperature was exceeded On the other hand, lesser degrees of cold have very little local effect upon the tissues, and correspondingly signs are very difficult to produce experimentally Smith, Ritchie, and Dawson[8] have produced swelling of the feet by standing rabbits for several days in cold mud and immersing them in hot water In other cases, however the animal was placed on dry mud at temperatures of +1° C to −1° C for over a week with only the slightest signs of swelling, especially when the warming was slow In yet other cases the temperature was kept at 0° C to − 5° C for as long as five days, and even although a constricting band was used there was no swelling when the legs were slowly warmed The greater number of their experiments were conducted with constricting bands which brings in an additional factor On the whole the impression derived from their article agrees with the writer's experience—namely, that it is difficult to produce any pathological change at temperatures above −6° C This being so it will be difficult to estimate the effect of placing the part in abnormal relationship to blood and nerves In the following series of experiments special attention was therefore paid to the condition of the vessels in those cases where temperatures above − 6° C were used, while in those below this temperature the swelling and blistering of the parts formed obvious indications As in the last group, the experiments were conducted upon rabbits' ears and legs and upon human skin

Experiments upon Rabbits

A.—All the nerves going to the left ear were blocked at the base with ½ per cent. cocaine Around the base of the opposite ear (control) a corresponding amount of Ringer's solution was injected Under general anæsthesia both ears were exposed to *freezing solution* at −20° C for 10 minutes and then immersed in water at + 40° C for a further 10 minutes The vascular changes during this experiment were exactly the same as those given in the corresponding experiment in the last group No swelling or other signs of frost-bite occurred the general congestion of both ears having passed off in 12 hours

B —The internal and external popliteal nerves (left) were blocked with 1 per cent cocaine in the popliteal space Control injection of Ringer into the right popliteal space Both immersed in freezing solution temperature − 6° C for 10 minutes The legs did not solidify transferred *to water at + 40° C* Slight transient congestion of both feet, no other swelling or other signs of frost-bite occurred

C —Injections similar to those in B Immersed in freezing solution temperature −16° C *for 10 minutes and then in water at* +40° C 2 hours later right foot slightly swollen left not swollen 12 hours later there was extensive swelling of the right foot and slight swelling of the left

D —Three minims of stovaine and glucose solution injected probably extrathecally, into the spinal column between the second and third sacral vertebræ. Right leg immersed in ice and salt at −15° C for 12 minutes and then in water at + 40° C Upon recovery from the general anæsthetic the animal was paralysed in both hind legs This passed off in the course of two to three hours 12 hours later there was extensive swelling of the right foot which lasted several days

Note —Spinal injections are difficult in rabbits owing to anatomical arrangements of the dura and cord In two other cases this experiment was attempted, but in each case a permanent paralysis of one leg occurred The animals were killed and at post-mortem examination a small area of œdematous tissue was found surrounding the cord in the region of the injection These experiments are of interest, however, in view of the fact that in *one case* despite the exposure of the feet to freezing mixture at −12° C for 10 minutes, followed by water at +40 C, no signs of frost-bite occurred. In the third case slight swelling of one foot occurred after 12 hours

E —The perivascular tissues around the femoral vessels on the left side were infiltrated at two points with 1 per cent cocaine. Both legs immersed in freezing mixture at −15° C for 10 minutes and then in water at + 40° C One hour later there was slight swelling of the right foot. In 12 hours both legs were extensively swollen the right rather more than the left.

F —Dorsum of left foot infiltrated with 1 per cent cocaine ½ c c Dorsum of right foot infiltrated with adrenalin 1 in 10 000 ½ c.c Both immersed in freezing mixture at − 15° C for 8 minutes and then in water at 40° C 1 *hour left foot slightly swollen and hot; right foot* no swelling cold 12 hours left foot extensive swelling right foot no swelling 36 hours, left foot less swollen right foot now swollen. 72 hours left foot normal again right foot extensive swelling

G —Both feet immersed in freezing mixture at − 3° C for 20 minutes, and then in water at +40° C The left leg had an elastic constricting band above the ankle While chilled the right was bright pink in colour the left cyanotic Upon warming the right foot became blue and the left very congested and cyanotic 2 hours very slight swelling of the left foot right apparently normal. 24 hours both feet normal

Human Experiments

H.—N C L. May 15th Three areas on the forearm were exposed to CO_2 snow for 30 seconds The highest was used as a control the centre was completely surrounded by a ring of novocaine and adrenalin with deeper injections into the fascia to complete the blocking" The lower area was rendered anæmic by a piece of plate glass strapped tightly on to the arm In all cases the arm was immersed in water at +40° C at the end of the experiment The control area blistered within 10 minutes and eventually left behind a depressed scar The middle area showed slight signs of congestion *After two or three days there* was slight scaling of the cornified layer There was absolutely no swelling no blistering and no scar remained The lowest area blistered even more quickly than the control and a slough having separated has left behind a depressed scar

The experiment when repeated did not give absolutely constant results This depends in all probability upon the time of exposure and the type of skin For instance, in two cases (W E P and *N S*) the upper and lower areas blistered quickly as in Experiment H The centre area raised a small and imperfect blister after two to three days delay

I —M. A. O June 10th. Two areas the first injected with 1 per cent cocaine the second with Ringer's solution. Exposed to ice and salt at *−16° C for 12 minutes Within 10 minutes* the second area showed marked swelling the first although reddened was not swollen

J —W J C June 10th. Two areas one infiltrated with adrenalin 1 in 10 000 the second with 1 per cent. cocaine in Ringer CO_2 snow then applied to each for 15 seconds. After 15 minutes there was swelling of the second area, the first although reddened was not swollen. 12 hours second area covered by a large blister first area, except for discolouration was normal 30 hours the first area had started to blister 1 week both areas showed sloughing of equal extent

The conclusions drawn from this group of experiments are that in true frost-bite produced by temperatures below −6° C there is actual tissue destruction, due directly to the cold, the effects of which *it is therefore* impossible to prevent entirely by modifying either the blood or nerve *supply to the part* In the case of chilling alone produced by temperatures above −6° C, the normal congestion of the parts is not prevented by nerve blocking, although it may be less severe, it is, however prevented *by the local injection* of adrenalin, and to some extent also by local injection of cocaine The results obtained in the case of human skin agree very closely with those obtained in the limbs of rabbits

(5) *Conclusions Drawn from these Experiments with Regard to the Pathology and Treatment of the Effects of Cold*

In the short conclusions given at the end of each group of experiments we have drawn attention to the fact that cold below − 6° C has a very different effect from cold above that temperature and have suggested that this temperature must be considered as being decidedly critical in nature Constant results were obtained in all varieties of experiments and upon all tissues Many writers would appear to suggest that the effects of cold are slowly progressive and vary concurrently with the extent of drop in the temperature The curves given above show that this theory cannot be held The sudden drop at −6° C implies that at this temperature some additional *factor* occurs, probably in the nature of a physical change which destroys absolutely the protoplasmic content of the cell The changes occurring at temperatures above this point are changes of degree and of a chemical nature, once the freezing point of the protoplasm is reached, however, fundamental changes occur in the cells of a gross physical character The gradual depression in the curve which occurs in the region of +15° C fits in entirely with the above suggestion of chemical changes, and is probably explained in the following manner

The essential vital process of any cell is summed up in the word metabolism, and this consists of a delicate balance between anabolism and catabolism In the living cells the protoplasmic molecule by means of side chains attaches to itself certain anabolic products of food assimilation This chemical (query physico-chemical) union will require the absorption of a certain amount of energy At the same time the protoplasm is *being continually broken up* (*by* the total function of the cell) and metabolic products thrown off During this process a certain amount of energy will, of course, be liberated in various forms (heat, motion, &c.). Of these two processes anabolism being of the nature of a synthesis, and *requiring external energy in the form of heat* is the more easily affected by external agencies and may be considered to be the more delicate of the two During the process of chilling of the tissues, therefore, although both will be affected, we shall expect *a priori* that anabolism will stop before catabolism At *temperatures in the region* of +15° C anabolism may be assumed to have stopped entirely, while catabolism continues slowly When temperatures in the region of zero are reached catabolism also stops, and so it follows that tissues at the temperature of 0° C can be preserved for longer periods than *those at* +15° C The question of the effect of autolytic enzymes has been purposely ignored, for their function is so bound up with the metabolism of the cell protoplasm as to be included in the above suggestions The analogy to *some of the* high explosive compounds is fairly accurate *These* compounds are notoriously unstable, if raised to the explosive temperature rapid combination with oxygen occurs and the explosion results, this corresponds to normal cell metabolism If stored at rather lower temperatures they fairly rapidly degenerate into simpler and more stable compounds When stored at low temperatures, however, they retain their potential explosive properties over considerable periods being meanwhile quite stable At the risk of repetition we again state that the effects of cold below and above − 6° C respectively can in no way *be compared*—the one is chemical, the other physical, and the difference between them is as great as that between a mixture of hydrogen and oxygen gases in a tube and the water which results from their chemical combinations From this point onwards therefore, we shall divide these considerations into the effects of true "frost-bite" and the effects of chilling of the tissues

Effects of True Frost bite

Frost-bite produces actual destruction of tissue and, as a result, the pathological effects are numerous In the minor cases the destruction of the endothelial walls of capillaries allows of a rapid exudation of the fluids and also in some cases of the cells of the blood into the surrounding tissues In some cases the endothelial and other cells, by their destruction will set free tissue *extracts and so* intravascular clotting will occur This process may extend until the larger vessels are affected and lead to complete cutting off of the blood supply followed by gangrene In other cases the actual pressure of the exuded fluids will bring about the same result In the minor cases the destroyed tissues will be absorbed slowly by a process of aseptic inflammation and leave as a result a certain amount of fibrosis and scarring In the worst cases the whole thickness of the part is affected (this takes a considerable exposure, as the deeper tissues freeze slowly) and necrosis or sloughing occurs In addition to these results, in many cases there will be microbic infection with its concurrent effects Clinically the results of frost-bite are rarely seen in our temperate climate, but in other countries they are not at all uncommon. In Canada, for instance, a large number of cases occur every year and are often of the utmost severity It is interesting to note in this connexion that in the *Journal of the Royal Naval Medical Service*[*] a case of true frost-bite is recorded as occurring during an aeroplane flight at a height of 15 000 feet, the calculated temperature at this height being 34° below zero

It now remains to be seen whether we can prevent or in any way diminish these effects. Bearing in mind the pathology of the condition as given above, we should *a priori* expect that very little could be hoped for in the way of treatment The experiments detailed in Group 4 absolutely confirm this prognostication Whether the nerves to the part were blocked with cocaine or the blood supply was temporarily cut off the results were invariably the same If the vaso-motor nerves accompanying the blood vessels were blocked by perivascular infiltration with cocaine the results were no better There is however one exceedingly important observation which must not be overlooked—namely that the local injection of cocaine or, better, of adrenalin in one or two cases entirely prevented the exudation, and in all cases caused considerable delay and probably lessened the amount This delay in some of the cases amounted to three or four days The explanation of this phenomenon rests with the vaso-motor system With regard to the effects of temperature changes upon the calibre of the vessels, too much emphasis has been laid upon the nervous reflex. The above experiments would tend to show that the central mechanism in this case is quite subsidiary to the local one. It is a well known fact that involuntary muscle fibres react to temperature changes by contracting during falls and relaxing when the temperature is raised. The involuntary muscle of the arterial walls may be expected to form no exception. It must be remembered that the circulatory system may be divided up into four main types of vessels—namely, the larger arteries, containing very little musculature, the arterioles, which are exceedingly muscular, and which, in the normal condition of arterial tone, act as a dam protecting the capillaries through which alone exudation occurs, from the arterial blood pressure, and finally the veins with little or no musculature, but capable of great distension. The first effect of cold will be to contract the musculature of the arterioles This, as proved by some of the experiments in Group 3, occurs in the presence of nerve blocking and so must be due to the direct effect of cold upon the muscle The contraction of the arterioles occurs to such an extent as completely to obliterate the vessels The capillaries and veins will therefore be comparatively empty, while the larger arteries will be distended at full pressure, hence the red appearance of the parts by transmitted light When the part becomes frost-bitten, the muscles of the arterioles are destroyed As a result upon thawing the damming effect of the arterioles upon the blood pressure is lost and the capillaries become subject to sufficiently high pressure to cause exudation If the endothelial wall is also destroyed by the cold then the exudation will be all the more rapid and extensive. Both cocaine and adrenalin cause a local contraction of the vessels by direct effect upon their walls and so the vessels just beyond the frost-bitten area will remain contracted even when thawing occurs This will prevent the blood pressure in capillaries from rising and so no exudation occurs As the effects of the local injection begin to wear off, however the capillary pressure will rise and, should the wall have been seriously damaged by the frost bite delayed exudation will now occur If on the other hand the capillary wall is now normal no exudation will occur This appears to afford a simple and logical explanation of the phenomena of late exudation and of those cases where no exudation occurs the injury in these latter cases being submaximal and the capillary walls rapidly restored to the normal condition In the severe cases therefore nothing can be done In the milder cases, however it has been pointed out that, in addition to the actual direct destruction, there are the effects produced by the exudation itself. Indeed, a vicious circle is set up, for the greater the exudation the greater the venous obstruction, and the greater the venous obstruction the greater the rise in the capillary pressure, and hence the greater the exudation Although, therefore, it will be impossible to prevent or remedy the destructive effects of the cold, it would seem reasonable to attempt to limit the exudation and so to prevent additional damage This can be accomplished by preventing any considerable rise in capillary pressure, both by damming back the arterial blood and by ensuring quick venous return The former method has been carried out in this work by the local injection of vaso-constrictors, and although this method is impracticable in the majority of human cases, treatment by the use of intravenous injections of vaso constrictors is worthy of trial The disadvantage of all the vaso constrictors is that it is difficult, and in some cases impossible, to localise their action to the desired area, and, again, in some cases the effect is very transitory and followed by a reactionary dilation which renders the condition worse By the judicious use of injections of strychnine and ergot it should be possible to keep up a fair degree of vaso constriction over the first two or three days, and particularly is this necessary during thawing In discussing this suggested treatment with colleagues, it has frequently been objected that the use of vaso-constrictors in any condition approximating to gangrene is surely not indicated This objection undoubtedly holds in the case of severe frost-bite, causing necrosis of the part, for all that can be hoped for in such cases is the formation of a line of demarcation and the separation of the dead tissue In the minor cases of true frost-bite however, we believe that many of the evil effects are due to the excessive exudation and that therefore the use of vaso-constrictors to limit the exudation is indicated We have unfortunately, not been in a position to give this treatment a trial

The Effects of Degrees of Cold Above −6° C upon the Tissues

We now pass to a consideration of the effects of cold above the critical temperature upon the tissues, this will include one of the essential factors in the production of "trench foot"

S Delépine[11] has suggested the use of the term "frigorism" to denote this condition This English equivalent of the French "froidure" although not very euphemistic is certainly an improvement upon "water-bite"

In the condition of suspended animation brought about by such temperatures it should theoretically be possible to preserve tissues indefinitely, practically this is not the case It is certain, however, that tissues may maintain their vitality for periods of from six to eight weeks in this condition At the end of the first series of experiments we drew attention to the fact that in growths which had been stored for 16 days at +2° C the onset of the signs of diminished vitality did not occur any sooner than in the controls which were kept at +37 5° C In both cases the periods averaged five to six days of incubation It would appear, therefore that during the 16 days at +2° C no degenerative change in the tissues worthy of consideration could have occurred As we should expect also no oxygen is used up in this condition, for the slides are sealed and the supply of oxygen strictly limited and equal in the chilled specimens and in the controls The bright pink colour of the chilled parts in the third and fourth groups of experiments also indicates that the absorption of oxygen at these temperatures is reduced to a minimum Theories which assume that the changes are due to ischæmia cannot be accepted for the chilled tissues need neither nutriment nor oxygen Clinically it is found that the actual time of exposure rarely exceeds three or four days and in this time, in view of the above experiments we can scarcely assume any change in the actual cells of the tissue (from cold alone) likely to bring about the extensive swelling and sometimes gangrene which occur The essential process would appear to be exudation, the other changes—gangrene paræsthesiæ &c—can be easily explained as being secondary to the exudation and dependent upon it

The paræsthesiæ appear to have attracted the attention of many authors Fearnsides divides the cases up into those showing objective changes and those with subjective changes only (paræsthesiæ) and explains the latter as a neurosis or psychical anæsthesia Most observers (Fearnsides,[12] Watson and Myers [13] Swan[14]) agree that in the cases with most swelling the hyperæsthesia was least marked The clinical experiences of the writer agree with this It is possible to account for all these phenomena by assuming an interneural or even intra neural exudation into the larger nerves Obviously a slight degree of intraneural exudation will produce more subjective symptoms than a large degree of interneural exudation The exudation rarely occurs either experimentally or clinically before the part is warmed Failing a satis factory explanation from any direct effect of cold let us examine the vaso motor conditions during the warming process At the start the arterioles are contracted practically to obliteration, and pressure in capillaries and veins is at a minimum As the temperature rises the involuntary muscle fibres, having been in a state of tonic contraction for a considerable period, become relaxed and for the time paralysed An enormous dilatation of the arterioles, therefore, occurs and the full arterial pressure is transmitted to the capillaries Whether the endothelial walls of these be damaged or no, the rise of pressure is so great as to cause the fluid contents of the blood to filter through the walls in exactly the same manner as serum passes through a porcelain filter when the pressure is sufficiently raised This exudation will contain fibrinogen, and hence the deposit of fibrin in the tissues The exudation will now press upon the veins and so the vicious circle starts In the same way any artificial obstruction to the venous return will increase the capillary pressure, and therefore the exudation This probably explains the very marked increase in swelling which the presence of a constricting band produces, either experimentally or clinically, and indicates an important line of prophylaxis This great vaso-dilation is, we believe, more local than reflex in origin, since experimentally it occurs when all the nerves going to the part are blocked with cocaine

We should expect this condition to be much more difficult to produce experimentally in animals than in man, for in animals the musculature of the arterioles is normally subject to greater changes than in man, and so is less likely to be rendered paralytic by temperature variations The difference then, between the pathology of true frost-bite and of chilling lies essentially in the nature of the local damage In the first instance the cells are killed by cold, and therefore only in mild cases can any treatment be of much avail In the second instance the damage is secondary to the excessive exudation, and this to the great rise in the capillary pressure If, therefore, the capillary pressure can be kept low while the arterioles regain their tone, then the conditions will be amenable to treatment

Although, therefore the pathology of the two conditions is different, the treatment of both rests in preventing too great rise of capillary pressure The suggestions given therefore, for the treatment of frost-bite will apply equally well to the treatment of chilling Better than treatment however, is prophylaxis Any condition likely to bring about venous congestion (constricting bands puttees, tight boots, standing too long in one position &c) must be avoided Variations in the temperature will bring about more rapid paralysis of the arterioles than constant cold, and so should as far as possible, be avoided This is difficult to accomplish in a limb the blood supply of which is considerably diminished A thin layer of dry air surrounding the limb will help immediately

S Delépine[11] has suggested the use of imperishable oiled silk bags to be worn outside the socks as a practical means of attaining this end Indeed, we believe that the bad effects of water are chiefly brought about by its acting as a good conductor of the varying degrees of cold

It should be noted here that McNeil[10] calls the condition "water bite" and considers that it is due entirely to osmosis the tissue being distended with dilute plasma It is difficult to believe that any degree of osmotic action could occur through the thick protective skin of the feet, and, indeed, the experiments of Rideal and Waller[3] already quoted show that, experimentally swelling except of the superficial layers of the skin itself, is not produced even when the exposure is prolonged "Water bite" would therefore appear to be an unsatisfactory term, as it fails to indicate the primary factor

Once the limb has become definitely "chilled" treatment should be immediately started It would appear better to keep the limb cold by the application of wet cloths until efficient treatment can be given than to allow partial warming to occur The actual treatment will consist in using any and every means of preventing too great a rise in the capillary pressure As to whether the use of vaso-constrictors as suggested above, will be of any avail remains to be seen They should obviously be given before the part is warmed and once they are acting the parts should be warmed not too slowly If, on the other hand, vaso-constrictors cannot be given, then the part must be very slowly raised to the normal temperature, for this tends to diminish the degree of vasomotor paralysis Elevation of the limb and gentle massage, by aiding the return of blood and diminishing the capillary pressure, will be of value in after treatment They will also be of great use as a means of prophylaxis

During rest periods the legs should be elevated and not allowed to dangle over the edge of the dug out The legs should meanwhile be well massaged, for during the rest period partial thawing is very apt to occur and to start off the train of events The more powerful of the vaso-constrictors should be given immediately, if at all, and followed by those having gentler and more prolonged action These must be continued for the first three or four days

Treatment on these lines has not yet been applied to actual cases of "trench foot," as the opportunity has not arisen It may well be impracticable to bring about the desired vaso-constriction We feel sure, however, that it is along these lines that a satisfactory treatment should be sought

In conclusion, it should be mentioned that at one period it was hoped that blocking of the large nerve trunks or preferably of the cord itself by spinal injections of novocaine would give good results by stopping the reflex nervous dilatation of the vessels We have shown, however, that for the rabbit at least the dilatation is mainly the result of the local mechanism, whether it be directly muscular or through a local nerve reflex matters not. In transferring the results to man, however, caution must be used, for in this case the local mechanism may play a smaller part in the production of the condition If this be so, then we may still hope for some success by spinal injection, combined with the action of vaso constrictors and certainly in at least one case (exp 4 D) in which a spinal injection was given, no swelling occurred, although the leg was rendered solid by immersion at −12° C for 10 minutes

Summary

(1) The temperature −6° C must be considered critical in relationship to the effects of cold upon the tissues

(2) Degrees of cold below this temperature produce true frost-bite and actual damage to tissues

(3) Degrees of cold above this temperature only produce effects secondarily by causing vasomotor paralysis

(4) Nerve blocking does not prevent either the effects of frost bite or of chilling

(5) The use of vaso constrictors delays the swelling in cases of true frost-bite while in cases of chilling the exudation may be entirely prevented

(6) Satisfactory treatment of trench foot must be directed towards preventing any appreciable rise in capillary pressure

(7) In the production of trench *foot cold* must be considered the essential factor, other factors being either secondary or subsidiary

(8) Treatment by the use of vaso-constrictors, either intravenously or otherwise would appear logical and worthy of trial

(9) Treatment by nerve blocking, either regional or central, is also suggested, although in all probability it cannot be expected to give good results unless used in conjunction with vaso constrictors

(10) Prophylaxis consists in using any and every means of preventing congestion of the legs, and in avoiding, as far as possible variations in the temperature

(11) The question as to whether any surgical procedure such as temporary occlusion of the arteries, would bring about the desired reduction in capillary pressure is being investigated.

THE CHEMICAL AFFINITIES OF *VIBRIO CHOLERÆ*

BY LUCIUS NICHOLLS M D, B C, B A. CAMB,
DIRECTOR OF THE BACTERIOLOGICAL INSTITUTE, CEYLON LECTURER ON TROPICAL DISEASES TO THE CEYLON MEDICAL COLLEGE

A KNOWLEDGE of the susceptibilities and resistances of micro-organisms to various chemical bodies is of great importance For by the application of this knowledge we may obtain selective media for the isolation of bacteria and specific disinfectants or even substances of curative value in disease

In an investigation of the chemical affinities of an organism two end points may be determined—namely the greatest dilution of the substance which is being tested which will destroy the organism in a definite time, and the minimum amount in a culture medium which will prevent the growth of the organism I use a special apparatus consisting of a series of clamped multiple pipettes which enables the determination of these factors to be carried out rapidly

The *Vibrio choleræ* is an excellent example of an organism which possesses peculiar chemical affinities The first substances which were tested with this organism were various acids and alkalies and the dilutions of these were prepared from standard normal solutions All the dilutions in these experiments were made with 1 per cent. peptone water

Alkaline Media

Chart I shows the relative resistance of the *Vibrio choleræ* to caustic soda It is seen that the vibrios remain alive in peptone water containing 3 5 c c of N NaOH to every 100 c c whereas the other organisms such as *B typhosus* and *B coli communis* are far less resistant

In Chart I the last columns represent the results when a quantity of normal stool is mixed with peptone water and tested in the same manner as the cultures In this particular test the cholera vibrio was slightly more resistant than any organisms present in the sample of fæces, this hardly represents the usual results which have since been obtained in other experiments because certain fæcal bacteria such as *Bacillus acidi lactici* (Huppe) have the same resistance to alkalies and spore-bearing organisms have a much greater resistance than the cholera vibrio

Chart IA. demonstrates the amount of growth which takes place in alkaline media of various strength in 48 hours Thus the vibrio is capable of flourishing in a relatively strong alkaline medium Even when 3 5 per cent of N.NaOH was present in the media the vibrios grew on the surface with pellicle formation

Charts II, III, and IV represent the actions of sodium carbonate, sodium bicarbonate, and potassium bicarbonate respectively on the *Vibrio choleræ* and other organisms

The *Vibrio choleræ* grew abundantly in 48 hours in media containing 7 5 per cent and 10 per cent of normal sodium bicarbonate No growth of *B coli* took place in these strengths

Calcium hydrate was the next alkaline substance which was tested the dilutions were made by saturating with calcium oxide 1 per cent peptone water which had been thoroughly boiled to expel any carbonic acid gas which might be present The strength of this saturated solution was estimated by titrating with N/10 HCl and the various

Acid Media

The resistance of the vibrio to the action of alkalies has its counterpart in its susceptibility to the action of acids

The organism is killed in half an hour in a solution of peptone water which contains 1 5 per cent of normal hydrochloric acid It is not so readily destroyed in a broth solution of this strength of acidity, and the explanation of this may be that the acid has formed acid salts to which the organism is more resistant Numerous organic acids, such as lactic, butyric, caproic, valeric, and propionic were tested and gave very similar results Charts VI and VII show the results with lactic and butyric respectively

Chart VIII shows the results when phosphoric acid (H_3PO_4) was used

Most organisms are very resistant to the acid salts *B coli communis* will flourish in a medium containing 2 per cent of the acid phosphate of soda, and it is not destroyed in 24 hours in 7 5 per cent solution of this salt The cholera vibrio is relatively as susceptible to the action of acid salts as it is to the action of acids, the results of an experiment are shown in Chart IX

A large number of salts were tested next, and as a general rule it may be stated that the vibrio is killed more rapidly by the action of salts than any organisms of the typho-colon group The action of calcium chloride was an exception to this, for the vibrio exhibited almost as much resistance to this body as *B coli communis* Chart X and XI show the results with sodium chloride and calcium chloride respectively

These experiments demonstrate that the cholera vibrio is more resistant to alkalies than most organisms, and that it is particularly susceptible to the action of acids and many aniline dyes. The results obtained with brilliant green are the most extraordinary of all the chemicals which I have tested up to the present date.

Isolation of the Organism.

Many alkaline media have been used for the isolation of the vibrio, and the best known of these is Dieudonné's alkaline serum agar. These media possess disadvantages, for when vibrios are scantily present in the inoculated material their growth is inhibited, and there is a tendency for the characteristic curve of the vibrio to be lost. Recently I have used media prepared with calcium oxide, and this eliminates these disadvantages.

An excellent medium for subcultures of the vibrio is prepared by saturating nutrient agar with lime, filtering, and then carbon dioxide is bubbled through the medium and most of the lime is precipitated as calcium carbonate. When this medium is filtered again it will be found alkaline to litmus, even after carbon dioxide has been passed through it for one hour. The vibrio grows very luxuriantly upon this medium.

The following, selected from a number of similar experiments, is a method of isolating this organism when it is present in high dilution.

Three litres of unboiled tap-water were placed in a flask and about 50 gm. of a normal stool and five broth cultures of certain fæcal organisms, including *B. coli communis* and *B. acidi lactici*, were added to this. Of a 24-hour-old culture of *Vibrio choleræ* 1 c.c. was diluted with 999 c.c. of tap-water and thoroughly shaken, 1 c.c. of this dilution of 1 in 1000 was diluted with 99 c.c. of tap-water; this gave a final dilution of 1 in 100,000, of which 1 c.c. was added to the flask. Calcium oxide 1·2 gm. and 30 gm. of Witte's peptone were placed in the flask. A pellicle formation appeared on the surface of the fluid in two days and this was found to consist principally of cholera vibrios from which a pure culture was obtained.

Another method of isolating the vibrio from the excreta of patients consists in placing 5 c.c. of the excreta into three test-tubes and titrating with a soda solution of known strength until these tubes contain 3·2, 3·5, and 3·75 per cent. of normal caustic soda. At the expiration of an hour, when the alkali will have destroyed many of the normal fæcal organisms, the contents of these tubes are poured into separate flasks of peptone water and in this a culture of vibrios rapidly develops.

Several points of practical significance depend upon the susceptibility to acids of the cholera vibrio.

The stools from patients suffering with cholera rapidly undergo acid fermentation, and this is due purely to the presence of a quantity of undigested food material. A favourite method of submitting a specimen for examination from a post-mortem is to allow the intestinal contents to flow into a loop of intestine which is then ligatured, removed from the body, and forwarded to the laboratory; an acid fermentation takes place in this loop of intestine even more rapidly than in a rice-water stool.

I have received specimens for examination which have possessed an acidity up to 0·395 per cent. lactic acid equivalent. In several cases these have been tested by sterilising and then inoculating with the *Vibrio choleræ*, and the organism has died out in a short time. Specimens having an acidity above 0·25 per cent. lactic acid equivalent have proved to be valueless for examination. But the organism has been isolated from intestinal and fæcal particles in a pabulum of 0·2 per cent. lactic acid equivalent by first neutralising the acidity and then breaking up all solid particles with a glass rod.

The relative amounts of acidity produced in lactose or glucose media by the cholera vibrio and the commoner fæcal organisms are shown in Chart XIX.

CHART XIX.

Acidity reckoned as lactic acid produced—	*V. choleræ*	*B. coli communis*	*B.* [illegible]	*B. acidi lactici* organisms
In 48 hours in 37° lactose media	0·090%	0·207%	0·200%	0·163%
In 10 days in 37° glucose media	0·104%	0·251%	0·207%	0·217%

Much of this acidity certainly is not due to free acids, such as lactic acid.

A number of fæcal organisms were grown for 24 hours in tubes of glucose broth. These cultures were sterilised at 70° C., and each was divided into two portions, one of which was rendered neutral to litmus, these portions were inoculated with *Vibrio choleræ*, in every case the result was the same, the tubes which were not neutralised were sterile when tested after 24 hours, whereas in those which had been neutralised there was a growth of *Vibrio choleræ* Thus the acidity produced by fæcal organisms destroys the vibrio, but the other products of these bacteria do not prevent the rapid growth of this organism

Calcium carbonate is the best antacid to prevent the destruction of the *Vibrio choleræ* in excreta, and one or two drachms of this substance should be added to stools which are forwarded for bacteriological examination

Treatment

It would appear that the administration of acids was indicated in the treatment of cholera And theoretically the administration of the lactic acid or the products of fermented milk should give excellent results

Substances which usually are taken in with the food or are produced in the intestinal tract are easily dealt with by the animal or human economy A large number of experiments were carried out on rabbits and guinea pigs in an attempt to render acid the contents of the duodenum, jejunum, and higher parts of the ileum

Quantities of diluted lactic or butyric acid or soured milk were passed into the stomachs of these animals, and they were killed at variable times, ranging from five minutes to six hours after the administration of the acid, and in every case the contents were alkaline Only in those cases in which such large quantities of acids were administered as to excoriate the mucosa were the contents of the duodenum acid, and even then this acidity did not extend to the contents of the jejunum

These experiments were repeated with dogs and it was found that the contents of the small intestine of the common pariah dog are frequently faintly acid, and this degree of acidity cannot be increased by the administration of acids

It would seem impossible for this organism to survive in the acid contents of the stomach and reach the alkaline media of the small intestines unless it were very intimately mixed with solid particles of food, such as fats, which are not penetrated by the acid of the stomach

There is circumstantial evidence that the primary intracorporeal development of the organism takes place in the alkaline pabulum of the mouth and œsophagus, this is supported by the fact that in many patients suffering with cholera a large number of the vibrios can be found in the pharynx and in the œsophagus This may explain many of the vagaries of the disease

In considering the action of brilliant green and crystal violet upon the vibrio the question at once suggests itself Is it feasible to administer these substances to patients for the purpose of destroying or inhibiting the growth of vibrio in the intestine? I have carried out many experiments to test the action of these chemicals

Brilliant green 4 c c of a 1 per cent solution, was injected subcutaneously into the abdominal wall of a guinea pig which weighed 390 gm The animal showed no signs of general ill health and was killed after 24 hours An incision was made over the site of injection and the subcutaneous tissue was stained green and was very œdematous

Two other guinea pigs were injected with 3 c c of a 1 per cent solution of brilliant green, and large sloughs formed and separated at the site of injection, and the process of healing was very tedious, but both animals were alive and well four months after the injection

Rabbits may be inoculated intravenously with 0 25 c c of 1 per cent brilliant green for each 1000 gm weight, larger doses than this usually kill the rabbits

When the drug is administered to guinea pigs by the mouth it produces inflammation of the gastric and duodenal mucosa and intense congestion of the liver It is not readily destroyed by the acid of the gastric juice, and a large portion of the dye administered passes to the small intestine

Doses of 1/5 grain can be administered to dogs without producing poisonous symptoms, and when it is administered in a bolus of suet coated with keratin, and the animal is killed two hours after the administration, the presence of the green dye can be demonstrated in the intestinal contents by neutralising them with an acid

Further animal experiments are proceeding before testing this chemical upon patients suffering from cholera

NORMAL GUN-DEAFNESS

BY T B JOBSON, M D DUB

IT is well known that exposure to gun fire may cause deafness Oft-repeated loud noises will produce lessened acuity of hearing In previous wars it has been noticed that a small proportion of those exposed to gun fire showed signs of deafness so it occurred to me that it would be of some interest and use to find out what proportion of soldiers exposed to gun fire go deaf, to measure, as far as possible, the amount such deafness produced in a *previously healthy ear*, to ascertain whether this deafness is temporary or permanent, and to investigate the type of deafness so produced

With these objects in view I examined a large number of soldiers who were in hospital for various wounds All who did not show an interval of at least four months from date of exposure were excluded Seventy three showing this interval were examined Of these all giving a history of previous ear trouble were ruled out and also all those who showed severe nerve symptoms, fractured skull, abnormalities of nose or throat that would cause deafness or whose membranes showed signs of old otitis media or other abnormality The patients examined were Germans, and I must say they proved very intelligent subjects

To get anything like correct results with tuning fork tests the patient must concentrate on the subject and help the investigator all he can A few remarks on tuning fork testing may not be amiss here After trying forks of different wave lengths I decided to use C 2, which gives 512 double vibrations The lower forks take much longer before the sound ceases and although the lengthened period gives increased accuracy in judging the moment at which the fork is no longer heard the patient gets tired of concentrating for so long, and as the inquiry proceeds his answers get less accurate The higher forks are heard for such short periods that no accurate results could be obtained in an investigation of this kind No particular alteration of the tone limit was found, so the comparative tests were all done with the C 2 fork The men were tested by conversation as well, but the comparative results are difficult to obtain in small amounts of deafness The large majority—over 80 per cent—were quite unaware of being deaf at all This I have noticed over and over again in English soldiers, but on examination never failed to find some definite amount of deafness

The following are the details of the cases examined —Total examined, 73 Thirteen cases were excluded for the following reasons For old suppurative otitis media, 8, nasal obstruction, 1, enlarged tonsils, 2, head injury, 1, otorrhœa, 1

The conditions of the membranes in the 60 accepted cases were as follows Normal, 37, dull, 16, retracted, 3, increased mobility, 2, cerumen removed, 2

The average age was 28 Length of exposure to gun fire a few hours to several months Intervals since exposed four to six months

The type of deafness is a fairly definite one—mixed obstructive and nerve deafness In some cases hearing was normal in one ear, but in no case was hearing perfect in both The right ear was deafer than the left in the majority of cases The time of audibility of the C 2 fork at the meatus as compared with normal controls showed a reduction varying from 2 to 27 seconds the average being − 11 4 seconds for right and − 8 4 seconds for left Bone conduction showed a very similar reduction—viz, − 3 7 seconds for right and − 3 4 seconds for left.

A good many of the cases gave a history of severe or complete deafness for one or more days after exposure in a big "strafe" but almost invariably said they could now hear quite well The cases were all infantry men who would not be so close to big gun fire as the artillery On some future occasion I hope to examine some gunners and ascertain if their acquired deafness is more severe

From this investigation I fear it may be concluded that exposure to gun fire in the present war often produces rapidly a permanent deafness This normal—if I may so call it—gun deafness is of a very definite type—a mixed obstructive and nerve deafness The amount of deafness as shown by a C 2 fork is about − 10 seconds aerial conduction and − 4 seconds of bone conduction

A CASE OF TRAUMATIC RUPTURE OF THE HEART

BY G R. TURNER C B , F R C S ENG ,
TEMPORARY SURGEON-GENERAL, R.N
AND
LESLIE PEARCE GOULD D M , M CH. OXON
F R C S ENG
TEMPORARY SURGEON R.N

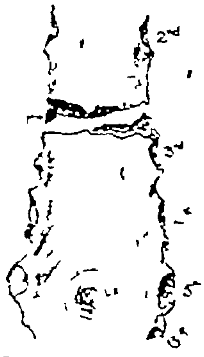
THE following case of traumatic rupture of the heart—an injury which has been reported in medical literature on only 95 occasions—appears worthy of record.

Mr G F , chief boatswain, aged 47, was leaning over the rail of his ship directing mooring operations when the rail carried away and he fell a distance of some 20 feet on to a buoy, and from there into a cutter lying alongside When picked up he was unconscious, but beyond small lacerated wounds of the chin and tongue no external injury was found He was transferred at once to the Royal Naval Hospital at Plymouth When seen on admission, an hour and a half after the accident, he was unconscious and was in a state of cerebral irritation, shouting out loudly, moving his limbs convulsively, and resenting all interference The pupils were dilated and did not react to light. There was no bleeding from nose or ears and no paralysis The extremities were pale and cold and the radial pulse was impalpable, while the heart sounds were noted to be distant and feeble There was no bruising of the chest wall, and examination revealed no sign of injury other than the small wounds of the face and mouth, and an abrasion of the scalp over the vertex, and bruising round both hips

During the next few hours his condition steadily improved, and when seen at 7 P M , five hours after admission he was conscious and rational He lay quietly in bed, and answered questions intelligently he complained of some abdominal pain, but made no other complaint His colour had improved and the extremities were now warm but the radial pulse was still impalpable, and the heart s action rapid and feeble

A few minutes later the sister on returning to the patient's room found him lying on his side, unconscious livid and breathing stertorously and within three minutes he was dead Immediately before death his eyes protruded abnormally, and his head and neck were intensely engorged and cyanosed A post-mortem examination was made the following day

FIG 1.



Posterior surface of the fractured sternum showing jagged edge A

The cranium was undamaged There was excess of cerebrospinal fluid at the base of the brain, the cerebral veins were congested and there was œdema of the brain but there was no gross injury There was a fracture of the first segment of the gladiolus of the sternum running obliquely downwards from right to left The periosteum over the anterior surface was not torn and there was no superficial ecchymosis, but the periosteum of the deeper surface was torn—evidently by the jagged edge of the fracture—and there was a small extravasation of blood into the anterior mediastinum The pericardial cavity was distended and appeared blue and on incising it 15 oz. of dark blood were evacuated After mopping this away a small tear was found in the anterior wall of the right ventricle close to the semilunar valves large enough to admit a lead pencil into the cavity of the ventricle There was a small bruise but no tear of the parietal pericardium immediately in front of this and the position of the rupture closely corresponded with the position of the left edge of the fracture of the sternum The right side of the heart was collapsed and empty The cardiac wall appeared to be healthy and of normal thickness and there was no fatty infiltration There was no other gross lesion of the thoracic or abdominal viscera and no other fracture

The diagrams (Figs 1 and 2) kindly drawn by Mr H S Holden temporary bacteriologist to the R N Hospital Plymouth show the position of the fracture and of the rupture of the heart muscle

The following facts about the case call for comment.

1 The injury was probably due to indirect violence as there was no bruise of the chest wall [illegible] that the man fell on his head, and that the fracture was caused by sudden acute flexion of the dorsal spine a mechanism which is known frequently to cause a fracture at the junction of the manubrium and gladiolus

2 It is noteworthy that the parietal pericardium was untorn permitting the sudden distension of the pericardium and death from compression of the right side of the heart.

3 The length of time that the patient lived after the accident can be explained by assuming, either that the rupture occurred at the time of the accident, and became temporarily obliterated by a clot or that the rupture did not occur until immediately before death, when a movement of the patient in bed displaced the upper fragment of the sternum backwards into the heart The first of these hypotheses seems more likely to be correct The fragments would be naturally kept in place owing to the anterior periosteum being intact and it is improbable that any voluntary movement of the patient in bed would be sufficient to drive the sternum backwards with sufficient force to rupture the heart Moreover the absence of the radial pulse and the extreme weakness and rapidity of the heart's action throughout suggest that there was an initial small hæmopericardium which became later increased by the dislodgment of a clot Corin [1] records a similar case which survived six days O'Neill [2] records the case of a boy who fell down and was stamped on He was kept in bed for two days and was then allowed up in the absence of severe symptoms remained apparently well for four days and died suddenly in bed on the following day The necropsy revealed a hæmopericardium and a slit 3 mm long at the auriculo ventricular valve In this case there was no fracture but it was indubitable that the rupture occurred at the moment of injury and became temporarily occluded.

4 In the absence of any local bruising or obvious crepitus the fracture was entirely overlooked, and the correct diagnosis was not entertained before death

FIG 2

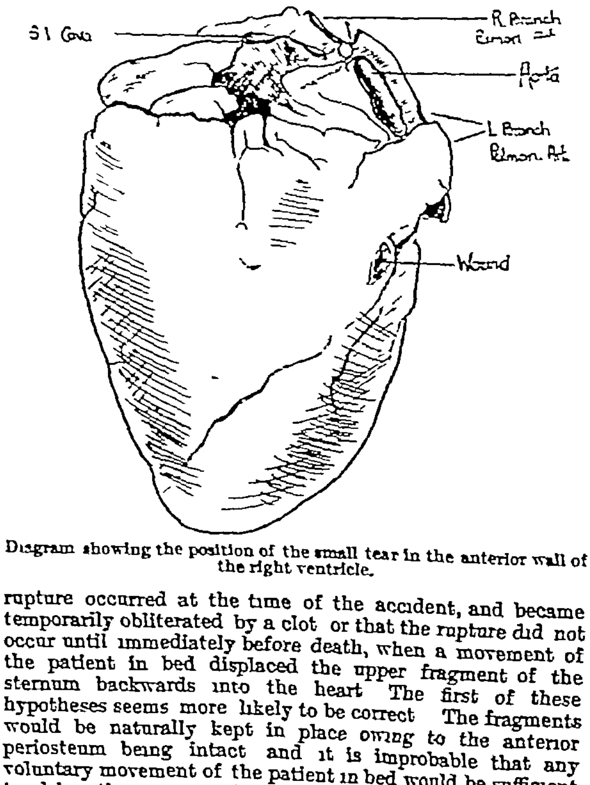


Diagram showing the position of the small tear in the anterior wall of the right ventricle.

BRISTOL HOSPITALS AND THEIR FINANCE —The medical report read at the half yearly meeting of the governors of the Bristol General Hospital showed an increase in the number of in patients while 50 beds had been placed at the disposal of the military authorities The financial report for the past six months was satisfactory —At the meeting of the governors of the Bristol Royal Infirmary the daily average number of in patients was reported to be 457 and the out patients 30,694 The financial statement showed a deficit on the six months of £4958 making a total adverse balance of indebtedness against the institution of nearly £20 000

GASTRIC DIGESTION OF VARIOUS FOODSTUFFS AFTER GASTRO-ENTEROSTOMY

BY A. A. WOLKOFF,
AND
E E KLOPFER

A Preliminary Note from the Pathological Laboratory of the Institute of Experimental Medicine, Petrograd
(*Director*, E S LONDON)

THIS paper is but a link in the chain of investigations which are being carried out in Dr E London's laboratories, an account of which will be found in his book "The Physiology and Pathology of Digestion" (Petrograd, 1916) In the course of time more detailed statements will be made concerning the experiments which we have performed

Gastric Evacuation after Gastro enterostomy

Under ordinary circumstances the movements of the stomach are directed towards pushing the gastric contents, the chyme, through the pylorus When an artificial opening is made between the stomach and intestine the manner of evacuation is altered in accordance with circumstances In such cases the state of the pylorus is of paramount importance If it is quite closed, then the evacuation of the chyme must be effected through the anastomotic opening If, on the other hand, the pylorus is quite passable the function of the anastomosis is more doubtful, though as yet no absolutely conclusive experiments have been made on this point Existing experiments incline us to the view that when the pylorus is narrowed but is still passable the gastro-entero-anastomotic opening does not function.

No doubt the position of the anastomosis is of some importance in this connexion, doubtless its size, direction, &c play a part also When employed on such investigations the research workers of the clinic usually use the Roentgen rays and opaque meal as the means of experiment But this method cannot compare for scientific accuracy with the making of fistulæ and direct observation on the outflow The shadows of the skiagram are often indistinct, and this method can give us no information as to the chemical composition of the evacuated food. Only the fistulæ method can give an answer to all the questions which arise The following points are in need of elucidation (1) Is a joint working of both outlets—i e, pylorus and gastro entero anastomosis—possible? and, if so, (2) is the emptying of the stomach accomplished through both outlets simultaneously or at different times? (3) if the evacuation takes place at different times, does it conform to some definite law? (4) does the chyme which comes from one outlet differ from that which comes from the other when different foods, such as milk, meat, &c., are administered?

Besides the purely practical importance of such an investigation—practical in view of the increasing application of the operation of gastro-enterostomy—this research has considerable theoretical interest, for by such experiments as these we can best determine the mode of gastric evacuation The best procedure is this Various dogs with identical gastro-intestinal anastomoses are taken and their pyloruses are narrowed in various degrees With the help of a fistula distal to the pylorus and another distal to the gastro entero-anastomotic opening we are able to study the passage of foodstuffs by both parts It must be admitted that such a set of protocols are difficult to obtain, because it is very difficult to cause a certain and constant narrowing or even obliteration of the pylorus Of late the fascial ligature has been much employed [1]

Our experiments on dogs with experimental fistulæ have convinced us that the fascial ligature of the pylorus however tightly it may be applied has no power to close the outlet of the stomach entirely The ligature does not answer the purpose, even when a strong silk ligature is put over the fascial one In fact, we have no mechanical contrivance by means of which a complete and definite closure of the pylorus can be effected The activity of the emptying stomach is so strong and is effected so directly against the pylorus that a very small opening will be made use of by the stomach Clinicians often hold other views based on skiagrams, for there are cases where a year or so after the application of the fascial ligature the X ray shows evacuation of the stomach only by way of anastomosis However roentgenographical shadows may easily give inexact information In one of our dogs, which had a narrowed pylorus and a wide gastro-enterostomy, minced meat passed both ways, whilst the more compact undigested parts found their way through the anastomosis Now bismuth, which produces the skiagraphic shadows is evacuated through the gastro-enterostomy as an indissoluble part of the gastric contents It does not pass at all through the pylorus, and if it does then in a greatly diluted state so that the shadows of the food which has gone through the pylorus are either invisible or very indistinct Under such conditions the X ray fails to give an accurate rendering of the manner of gastric evacuation

Results of Experimental Investigation.

The following remarks concern a dog which had been subjected to three successive operations —

A duodenal fistula was made on Oct 23rd 1913 When this wound was healed the pylorus was closed with a thick ligature, over which a piece of fascia taken from the dog's own thigh was tied and sewn This fascial band was peritonealised and an anastomosis was made between the pyloric portion of the stomach and the first loop of the jejunum (gastro-enterostomy antecolica) Below this a Braun's anastomosis was made between duodenum and jejunum to prevent a vicious circle Onwards from the fourth day after the operation the dog was put into a stand and there received either milk (100 150, 200 c c) or meat (200 gm) or bread (200, 150 gm) At first only duodenal juices, a brownish yellow transparent fluid of alkaline reaction, escaped from the duodenal fistula No food came away, the pyloric ligature evidently was successful But on the seventeenth day after operation acid drops and streamlets of gastric origin appeared mingled with the duodenal secretion On switching on the light in the vault of the cannula these acid secretions could plainly be seen coming from the oral side The secretions were collected and analysed After the seventeenth day the analysis proved that when milk was given to the dog the fluid collected from the duodenum contained sugar The sugar estimation was performed by Bertrand's method of analysis We came to the conclusion that the sugar was probably lactose When meat was fed to the dog the duodenal juice showed very clearly the biuret reaction As the pylorus was certainly now open again in spite of our ligature, it was necessary to find out whether the gastro-enterostomy was still working It could be surmised, *a priori*, that once the pylorus had opened its functional activity would increase in the course of time, whilst most probably the activity of the gastro-enterostomy would decrease in proportion Clinicians are of the opinion that the anastomosis would in this case become closed To clear up these questions we resolved to make a second fistula (a jejunostomy) below the entero-anastomosis If during the emptying of the stomach the duodenal fistula is kept wide open only such food as has escaped through the gastro-jejunostomy will be found in the jejunal fistula The jejunostomy was accordingly performed and it was found that the food left the stomach by both parts—the old natural way by the pylorus and also by the gastro-jejunostomy Our investigations showed, however, a difference in the character of the food which escaped by the two orifices, for the more liquid parts (milk beef juice) passed through the pylorus, whilst the more solid constituents (such as minced beef) came from the jejunal fistula

The work at this point was interrupted by the war, but will be resumed as soon as possible In the course of time more detailed statements will be made concerning the experiments which we have performed, as well as an account given of our further researches on the points enumerated above.

In conclusion, it is a pleasant duty to express our thanks to Dr E S London for the suggestion contained in this thesis as well as for his constant direction during the execution of this work.

A CASE OF COMPOUND FRACTURE OF THE PATELLA TREATED BY WIRING

COMPLETE FUNCTIONAL RECOVERY

BY J B HANCE, M B, B C CAMB, M R.C S ENG, L R C P LOND

CAPTAIN INDIAN MEDICAL SERVICE.

THE following account of an unusual case is given in the hope that it may prove of interest

G K, a Mahommedan, aged 20, was admitted to the Cantonment General Hospital, Agra under my care, on Nov 4th, 1916, at 3 A.M, for "wound of knee" The history was that on the previous night he had taken part in a Moharram procession and was indulging in the display of sword play customary on these occasions The sword hilt turned in his hand and the edge of the weapon struck the upper part of his left knee, the leg immediately gave way under him completely and he fell to the ground On admission the wound was at once thoroughly washed with antiseptic lotion by the subassistant surgeon in charge, the wound dressed, and the limb put on a back-splint

I saw the patient late on the same day, and, on examination confirmed the diagnosis of compound fracture of the left patella but it was then too late, with the limited lighting facilities, to attempt any operative measures Treatment was confined to the injection of 1500 units of antitetanic serum

Those readers of THE LANCET who are familiar with the resources of the average Cantonment Hospital in India, both as regards the possibility of aseptic surgery and skilled assistance will appreciate my difficulty in deciding on the line of treatment However I reflected that I might as well try wiring since ankylosis was almost certain to occur if the limb escaped amputation, a result which might be improved by wiring and could not very well be made worse Accordingly on Nov 5th the patient was anæsthetised and a thorough examination of the wound was made to gauge the chance of successful wiring

With the leg in the extended position on the splint the wound a wide obtuse angle lay with the apex of the obtuse angle just above what would have been in a normal limb the mid patellar point extending internally half an inch beyond the internal patellar margin while externally it reached a point one inch beyond the outer margin of that bone On opening up the wound to inspect the fragments it was seen that the sword must have impinged on the upper border of the bone for the whole of the anterior compact layer and the lower third of the entire bone formed the lower fragment while the upper was formed by the upper two-thirds of the articular surface, with the central cancellous tissue This curious solution of continuity is roughly shown in the accompanying figure The sword must have struck the knee when the latter was partially flexed, caught the patella on its upper edge, and cut cleanly down the upper two-thirds and broken off the lower third

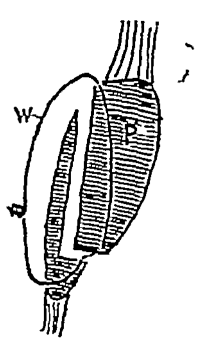

Diagram of fracture of patella (P) seen in longitudinal section The thick line shows the position of silver wire (W) in the fragments.

It appeared to me that the shape of the fragments admitted a reasonable hope of successful wiring, and that if one could prevent or control suppuration there was hope of the patient being left with a leg which if not functionally perfect, would at least be of more use to him than an amputation stump Accordingly the ordinary horse-shoe incision was made, joining up with the outer end of the wound externally, but half an inch internal to its inner end on the inside of the knee The resulting flap was turned down and the fragments exposed The joint was then cleared of blood clot and washed out with 1 in 2000 perchloride of mercury, followed by thorough irrigation with normal saline. The fragments were then drilled in the position and direction shown by the line in the figure, a stout silver wire passed, and the fragments securely fastened together The cut capsule of the joint was united by interrupted catgut sutures, as was the periosteum over the anterior surface of the patella, a rubber drainage tube being inserted into the joint cavity, externally and internally The remainder of the operation wound was closed by interrupted salmon gut stitches The edges of the sword wound were then pared with scissors, and united also by interrupted salmon gut sutures Dressings were applied and a back splint, and the patient was returned to bed. As soon as he came round from the anæsthetic weight and pulley extension was applied to the leg

On the next day the patient's temperature was 101° F, and my hopes for a good result fell almost to zero, but on changing the tubes I was relieved to find that, while there was plentiful discharge of serum and synovial fluid, nothing like pus could be noticed on the gauze or irrigated out of the joint The latter was thoroughly washed through with a hypertonic mixture of sodium citrate and saline, the tubes replaced, dressing reapplied, and the patient returned to bed A notable feature of the dressing, not only on this first day, but throughout the case, was its freedom from pain, the patient who was very nervous, assuring me after each sitting that he had not been once seriously hurt

The above procedure of dressing was repeated twice daily till Nov 22nd, when the evening temperature, after a steady decline, reached normal, the discharge remaining serous From this date it was performed daily till the wound healed Tubes were removed on Dec 4th and replaced by gauze drains, which in turn were rapidly replaced by drains formed of silkworm gut On Dec 23rd the sinuses had completely healed and massage was started

On Jan 5th 1917 the patient was discharged, at his own request, to attend as an out-patient for massage and I saw him for the last time on the day before I left Agra on service Jan. 17th when he was able to walk well with a stick and could bend his knee to less than a right angle without pain My successor Major H T Stack, R.A.M C, has kindly kept track of the case for me, and to him I am indebted for the information that when seen on March 11th this patient could walk and run, and that on May 13th he was able to squat native-fashion on his heels, and sit cross legged all day at his work boot-making This has been the test of cure that I set myself for if a man can squat and sit cross legged there cannot be much wrong with his knee joint, and I am informed that there is no appreciable functional or visible difference between the two lower limbs

Throughout the operation and the subsequent dressings, as far as local conditions permitted the strictest aseptic precautions were maintained The wound was handled as little as possible with the instruments available and no instrument touched the wound a second time that had not meanwhile been re sterilised I consider that the patient owes the fact that he has a perfectly useful knee to this procedure to the undoubted resistance possessed by the native of India to infection which would kill a European and above all to the unremitting care and attention of Civil Subassistant Surgeon Hamid Hasan Khan The latter throughout the entire case performed the combined duties of house surgeon, dresser, and nurse with an energy and attention that never flagged.

THE SURGING GALVANIC CURRENT IN THE TREATMENT OF PARALYSIS

A SIMPLE METHOD OF LOCALISING CONTRACTION TO PARALYSED MUSCLES

BY E P CUMBERBATCH, M A., B M OXON , M R C P,

MEDICAL OFFICER IN CHARGE OF THE ELECTRICAL DEPARTMENTS OF ST BARTHOLOMEW'S HOSPITAL, THE MILLER HOSPITAL, AND THE FIRST LONDON GENERAL HOSPITAL.

IN the electrical treatment of paralysis it is necessary to prevent any stretching of the paralysed muscles And in the opinion of many it is essential that the paralysed muscles should be made to contract and relax during the treatment The various electric currents, if applied in the customary ways by means of electrodes placed on the limb or in water immersing the limb will cause contraction of the healthy muscles whatever the condition of the paralysed muscles may be. Such contraction usually overpowers the latter and stretches them When the paralysis is caused by nerve injury and the muscles show reaction of degeneration, the faradic and sinusoidal currents will not cause any contraction of the muscles supplied by the injured nerve On the other hand, the antagonists, if healthy, will contract and cause passive stretching of the paralysed group The galvanic current will, at make, cause a slow contraction of the muscles showing R D , but such contraction is accompanied by a brisk twitch of the healthy antagonists The paralysed muscles will therefore be stretched before each contraction, because their latent period is longer than that of healthy muscles

If the galvanic current is applied, not with *sudden* rise to full strength and equally abrupt fall to zero as in the customary way, but with a more *gradual* increase of strength to maximum and equally slow fall to zero and if at the same time it is made to flow longitudinally through the muscles along the direction of the fibres, contraction will then be produced only in the paralysed muscles with R D , not in the healthy muscles A galvanic current that is made to surge in this way will therefore cause contraction of the paralysed group and stretching of the healthy antagonists An additional advantage attending the use of the surging galvanic current is that the limbs requiring treatment can, in many cases, be immersed in warm water without any support other than that afforded by the bottom of the receptacle in which the limb rests By immersion in water the maximum strength of current can be borne with the minimum discomfort and, further, the other tissues of the limb receive stimulation and an increased supply of blood both of which, in the opinion of the author, play an important part in the electrical treatment of paralysis Any stimulation of the normal antagonist muscles of the limb is an advantage, provided that it does not cause them to contract sufficiently to overpower and stretch the paralysed group because the former are deprived of much of their exercise when they receive no opposition and at the same time cannot shorten owing to fixation of the joint by splints in the intervals between treatment

Apparatus for the production of the surging galvanic current —Some device that will allow quick or slow increase and decrease of the current in either direction is required Further, if the current is derived from the main a rheostat and resistance lamps are necessary The water rheostats in use in the electrical department at the First London General Hospital and St Bartholomew's serve the second requirement admirably They allow the finest and most perfect gradation of the current and they cost very little To produce the surging the same water rheostats can be used but some modification is necessary for the most effective work The apparatus known as the "Galvanoset" made by the Medical Supply Association can be used for the purpose but the milliampèremeter attached to it is not really necessary and adds considerably to its cost. The writer has devised a simpler form of water rheostat which serves both requirements satisfactorily It is being made by the Medical Supply Association The principle of the water rheostat (which was originally introduced from France) may be briefly described

A cylindrical glass or china vessel is filled with tap water inches in diameter and 4 inches in depth is a suitable size Two carbon rods, 6 inches long, are placed vertically in the water at opposite ends (say one at north and the other at south) The current from the main is made to traverse the water from one carbon to the other The current to the patient is led off from the water by means of two other carbons, which also dip vertically into the water at the circumference, one at west, the other at east In this position no current flows to the patient But if the two latter carbons are moved around the circumference, one from west to south, the other from east to north, a current will pass to the patient, its strength gradually increasing the further the carbons are moved around the circumference If the carbons are moved in the opposite direction—viz , one from west to north, the other from east to south—the direction of the current to the patient will now be reversed The advantages of this form of rheostat are the perfectly even gradation of strength of the current, the ease with which it can be reversed, the safety to the patient, and its simplicity The movement of the carbons is easily effected by means of their attachment to a bar that rotates horizontally above the glass bowl, with its centre corresponding to the vertical axis of the latter The rotation is best effected by hand by means of a small milled-edge disc attached to the centre of the horizontal bar This method is adopted in the new model of rheostat devised by the writer By rotating the disc between the fingers and thumb the current passing to the patient can be made to increase and decrease, rapidly or slowly as desired, and in either direction

Application of the current to the body —To apply the current to the limbs say the upper extremities, the forearms are immersed in the arm receptacles of the Schnee bath, each forearm in a separate receptacle The electrodes are placed in the water at the ends occupied by the fingers (not at the ends occupied by the elbows) so as to ensure the passage of the current longitudinally through the muscles If the lower limbs require treatment the legs are immersed in the appropriate receptacles The electrodes however, should take the form of metal discs with vertical rods attached to them The discs rest on the bottom of the receptacles and the vertical metal rods are covered by rubber tubing where they are in contact with the water Such an arrangement ensures the longitudinal flow of the current through the legs With the ordinary electrodes the current may pass out of the legs to the electrodes in a transverse or oblique direction The current is now made to surge between zero and the maximum desired If the muscles are healthy they will not contract whether the surging is quick or slow If the current is made to reach a great intensity—i.e , as strong as can be tolerated —some slight degree of contraction of the muscles may be noted This is more often the case when the galvanic current supplied *to* the rheostat is not perfectly even and steady When this current is derived from a motor transformer (as is usually the case when the current from the main is alternating) this unevenness is frequently observed It does not seem to materially affect the action of the surging current when any of the muscles of the limbs are paralysed and show R D Suppose that this is the case with the extensors of the wrist It will then be found that as the current increases in strength, these muscles will contract and raise the wrist and hand. As the current falls to zero the muscles again relax It is sometimes found that the best contraction of the paralysed muscles is produced when the surging current *descends* the limb—that is flows from shoulder to hand Sometimes the best contraction is seen when it flows in the opposite direction—i e , when it *ascends*

In one case it was noted that the paralysed group contracted first and that as the current was further increased the healthy antagonists contracted and overpowered the paralysed group It is therefore advisable when beginning the treatment, to grasp the immersed wrist or ankle and note which current produces the best contraction of the paralysed muscles Sometimes a quick rise from zero to maximum is required as quick as can be effected by hand Usually a much slower rise produces the necessary contraction

In some cases the muscles with R D have greatly diminished excitability A surging galvanic current that reaches a strength sufficient to cause contraction of these will usually cause a stronger contraction of the antagonists so that the former are overpowered and stretched In these cases it is necessary to localise the current to the paralysed muscles This can be done by removing the limb from the water and applying an electrode so as to cover the affected muscles and causing the current to surge as before It may even be necessary to localise the electrode to the peripheral end of the muscle so as to ensure the passage of the current in a longitudinal direction through the muscle In one case of injury of the external popliteal nerve and paralysis of all the muscles supplied, with R D, it was noted that when the leg was immersed the surging galvanic current caused contraction of the anterior tibial groups of muscles and raising of the foot The peronei which had a lower degree of excitability, did not contract until an electrode was placed over the lower half of the peronei When the electrode covered the peronei *completely* it was noted that they did not contract, and when the current was further strengthened it spread to the anterior tibial muscles and caused contraction of this group

The contraction produced by the surging galvanic current is quite different from the brisk twitch that follows a single excitation of a normal muscle It is not a tetanus like that produced by rapidly repeated excitation of a normal muscle And it is not like the sluggish contraction *and relaxation* following excitation of a muscle with R D by the make of a galvanic current It however, resembles the continuous contraction (the so-called "galvano-tonus") which is so often seen in muscles with R D during the period of flow of the galvanic current, especially during the earlier stages of the paralysis This "galvano tonic" contraction bears a closer superficial resemblance to the voluntary contraction than that produced by other artificial methods 'Galvano tonus" can sometimes be produced in normal muscles when the current is strong

The writer does not wish to make any statement regarding the relative value of the surging galvanic current and the others commonly used The study of a large number of cases over a long period of time is necessary before any conclusion can be reached The surging galvanic current can, however localise contraction to the paralysed muscles, in two cases only, so far has the writer found it to fail In these the paralysed muscles had lost their excitability to faradic, galvanic and sinusoidal currents applied with the maximum strength that could be tolerated by the patient The method described has an additional advantage in that in a large proportion of cases, especially those that are fairly recent the limbs can be immersed in water without the labour of applying electrodes or fixing supports to them

CASE OF RUPTURED UTERUS WITH UNRUPTURED MEMBRANES

By HILDA SHUFFLEBOTHAM M.B, CH B BIRM,

HOUSE SURGEON WOMEN S HOSPITAL, BIRMINGHAM

With Note by S LEWIS GRAHAM, M S Lond, F R C S Eng

THE following case is of interest on account, amongst other things of its supposed rarity

Mrs A, aged 42, was admitted to the Women's Hospital Birmingham on Sept 8th, 1917, as an emergency case The history was that her general health had been very good until the last three years during which time she had suffered from chronic bronchitis She had had 15 pregnancies in 20 years 13 being full term All previous labours were normal and on admission she was at the full term of her fifteenth pregnancy On the day before admission she was doing her ordinary housework until 6 P M, when she commenced to have cramp like indefinite pains in the abdomen There was no vaginal loss and the patient did not think she was in labour The pains continued all night and at 6 o clock next morning she sent for a midwife who examined her and said she was not in labour but that she must call in a doctor At this time she had a sharp loss of bright red blood A local doctor came later in the morning and sent the patient into hospital Until admission at 2 P M the pains had gradually become more severe and the patient fel very ill Fœtal movements had been felt until the day before admission The condition on admission was as follows The patient was very fat and bronchitic She looked ill and was collapsed Temperature 98° F, pulse 130 and weak, breathing laboured and quicker than normal The abdomen was the size of full term pregnancy, it was painful and tender all over. Fœtal parts could not be made out definitely (The abdominal wall was fat, and the placenta lay in front of the fœtus) By the vagina there was some dark blood, the os felt thick, it was not on the stretch, and was about the size of a four shilling piece The fœtal head was felt indistinctly a long way up

An operation was performed by Mr Lewis Graham On opening the abdomen the maternal surface of the placenta presented immediately under the incision The membranes were intact and contained the fœtus cord, and liquor amnii There was dark blood clot in the abdominal cavity and the uterus was contracted down to the size of a coco-nut It had a rupture along its upper border and was quite empty The membranes were ruptured and the dead fœtus removed, which showed early maceration The placenta and membranes were then removed and a subtotal hysterectomy performed Blood clot and liquor amnii were mopped out, and the abdomen was closed with a drain to the bottom of Douglas's pouch

Pathological specimen The uterus was quite contracted down, and in this condition the rent was 6 in long At the site of rupture the wall showed marked degeneration, and at its edge was no thicker than a sheet of paper

The progress of the case was as follows The abdominal condition was perfect The patient had a sharp attack of pneumonia on Sept 19th

Note by Mr LEWIS GRAHAM

This is the third case I have had of rupture of the uterus with unruptured membranes and a dilated os In two the rupture was complete and the fœtus and its appendages have been free in the abdominal cavity In the third case the uterus had not quite ruptured through its whole thickness In each case the patient has had a large number of pregnancies in rapid succession This would appear to cause the uterine wall to give way under the tension exerted through the liquor amnii by the uterine contractions, but which tension is so slight as not to be able to cause rupture of the unsupported membranes at the external os In the case here reported it would be most interesting to know exactly when the uterus ruptured and expelled the fœtus into the abdominal cavity

A CASE OF ADENO CARCINOMA OF THE APPENDIX

BY JOHN A. C MACEWEN, M B, C M, B SC GLASG,

ACTING SURGEON GLASGOW ROYAL INFIRMARY CAPTAIN R.A.M C (T)
NO 4 SCOTTISH GENERAL HOSPITAL CONSULTING SURGEON
TO H R.H PRINCESS LOUISE SCOTTISH HOSPITAL FOR
THE LIMBLESS ERSKINE, ETC

THE patient, a man aged 43 was admitted to the Glasgow Royal Infirmary under my care on May 24th, suffering from symptoms of acute appendicitis He had been in good health until a week previous to admission, when he had severe pain in the right side of the abdomen, accompanied by sickness, vomiting, and giddiness The pain gradually disappeared, but owing to a slight swelling on the right side, which persisted, he was sent into hospital

On admission the patient had no pain, but there was a distinct tumour on the right side on the level of the umbilicus Temperature 99 2° F, pulse 112, respirations 28 An immediate operation was performed, and the tumour was *found to consist of matted omentum*, in the midst of which lay what was at first taken for a loop of much inflamed and thickened small bowel On investigation, however, the bowel" was seen to be greatly thickened appendix, the removal of which presented no special features of interest There was a considerable amount of purulent matter in the region of the mass, necessitating packing Patient made an uneventful recovery

Examination of the appendix after removal revealed a spherical white tumour, the size of a large marble, located in the *proximal end, involving* the greater part of the periphery of the wall of the appendix, and markedly blocking the lumen The appendix beyond the tumour was much thicker than normal, and the lumen much distended A microscopical examination of the tumour showed it to be of the nature of a papillomatous growth, with considerable inflammatory infiltration, while the deeper parts of the growth were adeno carcinomatous The tumour was almost confined to the mucous coat of the appendix

Glasgow

Mr Samuel Craddock, M R C S L S A of Bath, this month completes 50 years' service as coroner for North Somerset

THE SURGING GALVANIC CURRENT IN THE TREATMENT OF PARALYSIS

A SIMPLE METHOD OF LOCALISING CONTRACTION TO PARALYSED MUSCLES

BY E P CUMBERBATCH, M A , B M OXON , M R C P ,
MEDICAL OFFICER IN CHARGE OF THE ELECTRICAL DEPARTMENTS OF ST BARTHOLOMEW'S HOSPITAL, THE MILLER HOSPITAL, AND THE FIRST LONDON GENERAL HOSPITAL

IN the electrical treatment of paralysis it is necessary to prevent any stretching of the paralysed muscles And in the opinion of many it is essential that the paralysed muscles should be made to contract and relax during the treatment The various electric currents, if applied in the customary ways by means of electrodes placed on the limb or in water immersing the limb will cause contraction of the healthy muscles whatever the condition of the paralysed muscles may be Such contraction usually overpowers the latter and stretches them When the paralysis is caused by nerve injury and the muscles show reaction of degeneration, the faradic and sinusoidal currents will not cause any contraction of the muscles supplied by the injured nerve On the other hand, the antagonists, if healthy, will contract and cause passive stretching of the paralysed group The galvanic current will, at make, cause a slow contraction of the muscles showing R.D , but such contraction is accompanied by a brisk twitch of the healthy antagonists The paralysed muscles will therefore be stretched before each contraction because their latent period is longer than that of healthy muscles

If the galvanic current is applied, not with *sudden* rise to full strength and equally abrupt fall to zero as in the customary way but with a more *gradual* increase of strength to maximum and equally slow fall to zero and if at the same time it is made to flow longitudinally through the muscles along the direction of the fibres, contraction will then be produced only in the paralysed muscles with R D , not in the healthy muscles A galvanic current that is made to surge in this way will therefore cause contraction of the paralysed group and stretching of the healthy antagonists An additional advantage attending the use of the surging galvanic current is that the limbs requiring treatment can, in many cases, be immersed in warm water without any support other than that afforded by the bottom of the receptacle in which the limb rests By immersion in water the maximum strength of current can be borne with the minimum discomfort and, further, the other tissues of the limb receive stimulation and an increased supply of blood both of which, in the opinion of the author, play an important part in the electrical treatment of paralysis Any stimulation of the normal antagonist muscles of the limb is an advantage, provided that it does not cause them to contract sufficiently to overpower and stretch the paralysed group because the former are deprived of much of their exercise when they receive no opposition and at the same time cannot shorten owing to fixation of the joint by splints in the intervals between treatment

Apparatus for the production of the surging galvanic current —Some device that will allow quick or slow increase and decrease of the current in either direction is required Further, if the current is derived from the main a rheostat and resistance lamps are necessary The water rheostats in use in the electrical department at the First London General Hospital and St Bartholomew's serve the second requirement admirably They allow the finest and most perfect gradation of the current and they cost very little To produce the surging the same water rheostats can be used but some modification is necessary for the most effective work The apparatus known as the "Galvanoset" made by the Medical Supply Association, can be used for the purpose but the milliampèremeter attached to it is not really necessary and adds considerably to its cost The writer has devised a simpler form of water rheostat which serves both requirements satisfactorily It is being made by the Medical Supply Association The principle of the water rheostat (which was originally introduced from France) may be briefly described

A cylindrical glass or china vessel is filled with tap water, inches in diameter and 4 inches in depth is a suitable size Two carbon rods, 6 inches long, are placed vertically in the water at opposite ends (say one at north and the other at south) The current from the main is made to traverse the water from one carbon to the other The current to the patient is led off from the water by means of two other carbons, which also dip vertically into the water at the circumference, one at west, the other at east In this position no current flows to the patient But if the two latter carbons are moved around the circumference, one from west to south, the other from east to north, a current will pass to the patient, its strength gradually increasing the further the carbons are moved around the circumference If the carbons are moved in the opposite direction—viz , one from west to north, *the other from east to south—the direction of the* current to the patient will now be reversed The advantages of this form of rheostat are the perfectly even gradation of strength of the current, the ease with which it can be reversed, the safety to the patient, and its simplicity The movement of the carbons is easily effected by means of their attachment to a bar that rotates horizontally above the glass bowl, with its centre corresponding to the vertical axis of the latter The rotation is best effected by hand by means of a small milled-edge disc attached to the centre of the horizontal bar This method is adopted in the new model of rheostat devised by the writer By rotating the disc between the fingers and thumb the current passing to the patient can be made to increase and decrease, rapidly or slowly as desired, and in either direction

Application of the current to the body —To apply the current to the limbs, say the upper extremities the fore arms are immersed in the arm receptacles of the Schnee bath, each forearm in a separate receptacle The electrodes are placed in the water at the ends occupied by the fingers (not at the ends occupied by the elbows) so as to ensure the passage of the current longitudinally through the muscles If the lower limbs require treatment the legs are immersed in the appropriate receptacles. The electrodes however, should take the form of metal discs with vertical rods attached to them The discs rest on the bottom of the receptacles and the vertical metal rods are covered by rubber tubing where they are in contact with the water Such an arrangement ensures the longitudinal flow of the current through the legs. With the ordinary electrodes the current may pass out of the legs to the electrodes in a transverse or oblique direction The current is now made to surge between zero and the maximum desired If the muscles are healthy they will not contract whether the surging is quick or slow If the current is made to reach a great intensity—i e , as strong as can be tolerated —some slight degree of contraction of the muscles may be noted This is more often the case when the galvanic current supplied *to* the rheostat is not perfectly even and steady When this current is derived from a motor transformer (as is usually the case when the current from the main is alternating) this unevenness is frequently observed It does not seem to materially affect the action of the surging current when any of the muscles of the limbs are paralysed and show R D Suppose that this is the case with the extensors of the wrist It will then be found that as the current increases in strength, these muscles will contract and raise the wrist and hand As the current falls to zero the muscles again relax It is sometimes found that the best contraction of the paralysed muscles is produced when the surging current *descends* the limb—that is, flows from shoulder to hand Sometimes the best contraction is seen when it flows in the opposite direction—i e , when it *ascends*

In one case it was noted that the paralysed group contracted first and that as the current was further increased the healthy antagonists contracted and overpowered the paralysed group It is therefore advisable, when beginning the treatment, to grasp the immersed wrist or ankle and note which current produces the best contraction of the paralysed muscles Sometimes a quick rise from zero to maximum is required, as quick as can be effected by hand Usually a much slower rise produces the necessary contraction

In some cases the muscles with R D have greatly diminished excitability A surging galvanic current that reaches a strength sufficient to cause contraction of these will usually cause a stronger contraction of the antagonists so that the former are overpowered and stretched In these cases it is necessary to localise the current to the paralysed muscles This can be done by removing the limb from the water and applying an electrode so as to cover the affected muscles and causing the current to surge as before It may even be necessary to localise the electrode to the peripheral end of the muscle so as to ensure the passage of the current in a longitudinal direction through the muscle In one case of injury of the external popliteal nerve and paralysis of all the muscles supplied with R D , it was noted that when the leg was immersed the surging galvanic current caused contraction of the anterior tibial groups of muscles and raising of the foot The peronei which had a lower degree of excitability did not contract until an electrode was placed over the lower half of the peronei When the electrode covered the peronei *completely* it was noted that they did not contract, and when the current was further strengthened it spread to the anterior tibial muscles and caused contraction of this group

The contraction produced by the surging galvanic current is quite different from the brisk twitch that follows a single excitation of a normal muscle It is not a tetanus like that produced by rapidly repeated excitation of a normal muscle And it is not like the sluggish contraction *and relaxation* following excitation of a muscle with R D by the make of a galvanic current It however resembles the continuous contraction (the so-called galvano-tonus) which is so often seen in muscles with R D during the period of flow of the galvanic current especially during the earlier stages of the paralysis. This galvano-tonic' contraction bears a closer superficial resemblance to the voluntary contraction than that produced by other artificial methods Galvano-tonus ' can sometimes be produced in normal muscles when the current is strong

The writer does not wish to make any statement regarding the relative value of the surging galvanic current and the others commonly used The study of a large number of cases over a long period of time is necessary before any conclusion can be reached. The surging galvanic current can however localise contraction to the paralysed muscles, in two cases only so far has the writer found it to fail In these the paralysed muscles had lost their excitability to faradic galvanic and sinusoidal currents applied with the maximum strength that could be tolerated by the patient The method described has an additional advantage in that in a large proportion of cases, especially those that are fairly recent the limbs can be immersed in water without the labour of applying electrodes or fixing supports to them

CASE OF RUPTURED UTERUS WITH UNRUPTURED MEMBRANES

BY HILDA SHUFFLEBOTHAM M.B , CH B BIRM ,
HOUSE SURGEON WOMEN'S HOSPITAL, BIRMINGHAM.

With Note by S LEWIS GRAHAM M S Lond., F R C S Eng

THE following case is of interest on account, amongst other things of its supposed rarity

Mrs A aged 42, was admitted to the Women s Hospital Birmingham on Sept 8th 1917, as an emergency case The history was that her general health had been very good until the last three years during which time she had suffered from chronic bronchitis She had had 15 pregnancies in 20 years 13 being full term All previous labours were normal and on admission she was at the full term of her fifteenth pregnancy On the day before admission she was doing her ordinary housework until 6 P M when she commenced to have cramp like indefinite pains in the abdomen There was no vaginal loss and the patient did not think she was in labour The pains continued all night, and at 6 o clock next morning she sent for a midwife who examined her and said she was not in labour but that she must call in a doctor At this time she had a sharp loss of bright red blood A local doctor came later in the morning and sent the patient into hospital Until admission at 2 P M the pains had gradually become more severe and the patient felt very ill Foetal movements had been felt until the day before admission The condition on admission was as follows The patient was very fat and bronchitic She looked ill and was collapsed Temperature 98 F , pulse 130 and weak breathing laboured and quicker than normal The abdomen was the size of full term pregnancy it was painful and tender all over Fœtal parts could not be made out definitely (The abdominal wall was fat, and the placenta lay in front of the fœtus) By the vagina there was some dark blood , the os felt thick, it was not on the stretch and was about the size of a four shilling piece The fœtal head was felt indistinctly a long way up

An operation was performed by Mr Lewis Graham On opening the abdomen the maternal surface of the placenta presented *immediately under* the incision The membranes were intact and contained the fœtus cord, and liquor amnii There was dark blood-clot in the abdominal cavity and the uterus was contracted down to the size of a coco-nut It had a rupture along its upper border and was quite empty The membranes were ruptured and the dead fœtus removed, which showed early maceration The placenta and membranes were then removed and a subtotal hysterectomy performed. Blood-clot and liquor amnii were mopped out and the abdomen was closed with a drain to the bottom of Douglas's pouch

Pathological specimen The uterus was quite contracted down, and in this condition the rent was 6 in long At the site of rupture the wall showed marked degeneration, and at its edge was no thicker than a sheet of paper

The progress of the case was as follows The abdominal condition was perfect The patient had a sharp attack of *pneumonia on* Sept 19th

Note by Mr LEWIS GRAHAM

This is the third case I have had of rupture of the uterus with unruptured membranes and a dilated os In two the rupture was complete and the fœtus and its appendages have been free in the abdominal cavity In the third case the uterus had not quite ruptured through its whole thickness In each case the patient has had a large number of pregnancies in rapid succession This would appear to cause the uterine wall to give way under the tension exerted through the liquor amnii by the uterine contractions, but which tension is so slight as not to be able to cause rupture of the unsupported membranes at the *external os* In the case here reported it would be most interesting to know exactly when the uterus ruptured and expelled the fœtus into the abdominal cavity

A CASE OF ADENO CARCINOMA OF THE APPENDIX

BY JOHN A. C MACEWEN, M.B , C M , B SC GLASG ,
ACTING SURGEON GLASGOW ROYAL INFIRMARY CAPTAIN R.A.M C. (T)
NO 4 SCOTTISH GENERAL HOSPITAL CONSULTING SURGEON
TO H.R.H. PRINCESS LOUISE SCOTTISH HOSPITAL FOR
THE LIMBLESS ERSKINE, ETC

THE patient a man aged 43 was admitted to the Glasgow Royal Infirmary under my care on May 24th, suffering from symptoms of acute appendicitis. He had been in good health until a week previous to admission, when he had severe pain in the right side of the abdomen, accompanied by sickness vomiting, and giddiness The pain gradually disappeared but owing to a slight swelling on the right side, which persisted, he was sent into hospital

On admission the patient had no pain, but there was a distinct tumour on the right side on the level of the umbilicus. Temperature 99 2° F pulse 112, respirations 28 An immediate operation was performed, and the tumour was found *to consist of* matted omentum, in the midst of which lay what was at first taken for a loop of much inflamed and thickened small bowel On investigation however, the "bowel" was seen to be greatly thickened appendix, the removal of which presented no special features of interest There was a considerable amount of purulent matter in the region of the mass necessitating packing Patient made an uneventful recovery

Examination of the appendix after removal revealed a spherical white tumour, the size of a large marble located in the proximal end, involving the greater part of the periphery of the wall of the appendix, and markedly blocking the lumen The appendix beyond the tumour was much thicker than normal and the lumen much distended A microscopical examination of the tumour showed it to be of the nature of a papillomatous growth with considerable inflammatory infiltration, while the deeper parts of the growth were adeno-carcinomatous The tumour was almost confined to the mucous coat of the appendix

MEDICAL SOCIETY OF LONDON

President's Address —A Discussion on War Bread and its Effects on Health

A MEETING of this society was held on Oct 8th, when Sir STCLAIR THOMSON, the President, delivered an address on the Founder and the Foundation of the Medical Society

Dr ROBERT HUTCHISON and Dr E I SPRIGGS introduced a discussion on War Bread and its Effects on Health Dr HUTCHISON said that before discussing the effects of war bread on health it was necessary to know something of its composition The wheat berry consisted of three parts—the pericarp, germ, and endosperm In making ordinary white (pre war) flour only about 70 per cent of the wheat berry was used, the germ and pericarp being entirely discarded and used mainly for fodder In order to economise wheat it was now compulsory for millers to extract 80 per cent of the wheat berry as flour, and some of the pericarp and germ was included This Government regulation (G R) flour was the basis of war bread Chemically such flour was richer in every constituent except starch than wheat flour, and in particular it was richer in vitamines and phosphorus The question of its absorbability as compared with white flour was still *sub judice*, but there was no reason to suppose that it was inferior in this respect to white flour provided it were finely ground War bread, however, was not always made from G R flour only The addition of other cereals (maize, barley, rice, oats) up to certain limits was allowed The proportion of these added by different millers varied, and it had been found impossible to standardise the flour for the whole country None of the added cereals, however, could be regarded as injurious, and all were valuable foods Maize had come in for most popular criticism, but if properly ground there was no harm in it, and much of the hostility to it was due to prejudice As regards the bread, it must be recognised that it was impossible to prepare from the present flour a bread which had the same *æsthetic* qualities as pre war bread. The darker colour was of no importance, but the relatively lower proportion of gluten, especially when other cereals were added, caused the bread to be less porous This drawback would become less as bakers acquired more experience with the flour As regards its effect on health, it seemed certain that there was nothing *chemically* injurious in war bread , indeed, it was superior from a chemical point of view to white bread Any ill effects could only be due to its *mechanical* properties (presence of grit, doughiness, &c), and could only affect the digestive organs The quality of the bread produced in different parts of the country, and even by different bakers, varied greatly in these respects, but from fairly wide inquiry there was no real evidence of any serious disturbance of digestion by the bread in the great majority of individuals It must be remembered that patients were apt to find in the war bread a convenient explanation of any disturbance of health for which they could not otherwise account In cases in which the bread seemed to disagree the effect of toasting and more thorough chewing should be tried. The speaker had not himself seen any patient in whose case he was convinced that the bread had affected the digestion unfavourably

Dr SPRIGGS said that he had not found it necessary to order white bread for the patients in Duff House, although there was always a good number of sufferers from digestive complaints The war bread was, however, much better in some districts than in others, and their experience was, perhaps, fortunate The complaints which followed the measures taken by the Government to make good the lack of wheat by the use of other kinds of corn arose from several reasons The change in flavour was one reason Another one was the lack of skill and experience in making the bread with the new kinds of flour Further the mass of our people did not realise before the war that the cereals given to animals were good human foods, and did not know that by eating oats, barley, or maize ourselves we could get from them many times the food value that was obtained by turning them first into animal food He referred to the figures of Professor T B Wood, who calculated that of nearly 17 million tons of various kinds of corn used in this country before the war only 5 millions went for human food This was less than the average production of home grown corn, which amounted to 6½ millions tons Dr Spriggs said that he had advocated the use in home-made bread of a mixture of barley flour or meal, oatmeal, rice, or maize, in the proportion of one part of the meal to two parts of wheat flour or war flour This was a higher proportion of other cereals than millers were using at present (Examples of these different kinds of bread were shown to the meeting and tasted by the members Breads were also shown in which the added cereal had been boiled before mixing with the flour, making a spongier loaf) In order to compare the digestibility of such bread with that made from wheat flour experiments had been made by Mr A B Weir, B Sc., chemist at Duff House, and himself The subject was a healthy young man who took a mixed diet containing the same foods and in the same quantities every day, each article being weighed or measured accurately The diet was was follows —Breakfast Eggs, butter, bacon, marmalade, cocoa, milk Dinner Fillet of beef, potato, cabbage rice pudding, tinned pears, butter, cream, black coffee Tea Butter, jelly, milk, cocoa Supper Clear soup, haddock butter, cheese, coffee, milk With this a loaf of bread weighing about a pound was eaten daily The bread was composed of two thirds of white flour and a third of the meal or flour to be tested, and was made as described in Chapter IX of "Food and How to Save it."[1] These breads were compared with bread made from white flour alone, also with a war bread containing 10 per cent barley and 10 per cent maize All the breads were palatable and were preferred by the subject to baker's bread with the exception of that made with maize, the proportion of which (33 per cent) was too high for making nice bread The war bread, which contained 10 per cent of barley and 10 per cent of maize, was thought to be one of the nicest Each experiment lasted three days The flours were analysed separately The other foods were all minced, mixed together, and analysed The excreta for each three days were collected and their composition determined The results were given to the meeting and showed that, although there were differences in the amount of protein, carbohydrate, and fat assimilated, yet the variations were not of importance, the total amount of foodstuff assimilated when expressed in calories being almost the same in each experiment—namely between 95 and 96 per cent of the food value eaten The experiments demonstrated that bread composed of mixed cereals in the proportions recommended was palatable and, in this subject proved as nutritious as white bread

Professor W H THOMPSON, adviser to the Ministry of Food, said that it was important to get our protein food from a number of sources, because all proteins were not "adequate" for both growth and maintenance Even maize had about one third of its protein of the adequate type He thought that much of the trouble was due to ignorance in milling and baking In the early days millers were not fitted out to grind maize to a sufficient degree of fineness Observations were now being carried out which he hoped would enable all that difficulty to be overcome Samples of bread complained of had been sent to the Ministry of Food but in no case could anything be found wrong except the colour

Dr E KINGSCOTE said that he had been in North Italy before the war, where a large part of the community lived altogether on maize, many having no other food, but they were well nourished and healthy He thought that the admixture of two flours might be the cause of the difficulty The grinding of the maize was not equal to the grinding of the wheat, and in baking each required a different amount of time to arrive at perfect cooking

Sir STCLAIR THOMSON said that the important matter of bread did not escape Lettsom's attention It was gathered from his writings that the price of the quartern loaf in 1774 was 8*d* but by 1800 he wrote that the quartern loaf was 1*s* 6*d* , 'a sum truly oppressive to the poor" With our present-day quartern loaf at only 9*d* after three years of world war our population might take courage by seeing what our forefathers had to endure in the Napoleonic struggles In 1774 Lettsom, amongst his numerous essays printed one entitled "Hints respecting a Substitute for Wheat Bread " The substitute he warmly recommended was the fine flour of Indian corn to be mixed with that of wheat in equal proportions He added that, if rightly managed the colour would be about the same as the standard wheaten bread and about 2*d* in the quartern loaf cheaper than the fine wheaten when that might be at 8*d* per quartern. After insisting on the great nutritive value and the agreeable sweet flavour of maize, he wrote that some, indeed, did not so easily reconcile themselves to it which often arose from the mismanagement of grinding the corn or baking the bread The bakers, he said, had not acquired the best method of mixing and preparing it with wheat flour, and as to the grinding he advised that the millstones should first be set so wide as but just to burst the thick or farinaceous part of the grain, which should then be passed through a sieve so as to separate the part of the interior edge of the grain composed of a ligneous spongy substance, the middle of which was of a dark brown colour and of a bitter taste, which, if ground into the flour, gave it a disagreeable flavour When this deleterious part had been separated on the sieve the remainder should be ground with the stones set so as to render it sufficiently fine. Lettsom also suggested the use of potatoes as a partial substitute for bread, and recommended the use of one-fourth of potatoes with the remainder of flour He pointed out that if a little ground rice were added the bread was prevented from crumbling, a matter of consequence in a large family

Reviews and Notices of Books.

The New System of Gynæcology Edited by THOMAS WATTS EDEN, M D Edin., F R C S Edin., F R C P Lond., Obstetric Physician Charing Cross Hospital, Surgeon Chelsea Hospital for Women and CUTHBERT LOCKYER, M D, B S Lond, F R C S Eng, F R C P Lond., Obstetric Physician to Out-patients Charing Cross Hospital, Surgeon to In patients, Samaritan Free Hospital. In three volumes With numerous illustrations in colour and black and white. London Macmillan and Co 1917 Price £6 6*s*

THIS work is really a second edition of the System of Gynæcology' published in 1906 in association with Clifford Allbutt's System of Medicine. We quite agree with the editors when they maintain that the gynæcologist is a surgeon rather than a physician, but the best combination is that of physician and surgeon which exists when he practises both obstetric medicine and gynæcological surgery as he does in most of the larger hospitals in this country We do not believe in the divorce of gynæcology from obstetrics The gynæcologist certainly should have an acquaintance with the diseases of the kidney rectum and bladder but we hardly think that diseases of the breast fall within his province nor do we believe that the majority of gynæcologists treat these diseases In our opinion, therefore the editors have been ill advised to burden an already large book by the addition of sections dealing with these surgical affections The specialist who wishes to study the diseases of these organs will not refer to a treatise on gynæcology he will consult rather a treatise on surgery and in this he would be showing his wisdom. The result of the inclusion of these sections is three volumes where two might have been sufficient and a considerable increase in the cost of the book. No doubt the sections on general surgery which have been included are very good as far as they go but naturally they cannot be so full as they might and probably would be in a System of Surgery For these reasons we shall make little reference to them although several of them are of great merit.

The work has been issued in three volumes containing in all some 2507 pages The format, printing and paper are a great improvement on the original edition, and the whole is a most readable System The first section in Vol I is a good, but too short account of the Anatomy of the Pelvic Organs by Professor Elliot Smith and Dr J S B Stopford We wish that the editors had allowed them more space. In the second chapter Miss A L McIlroy discusses the Physiology of the Female Reproductive Organs She regards the luteal cells as the undischarged follicle cells a view in direct contradiction to that expressed by Dr Lockyer and Dr H Williamson in other parts of the book. The section is good and complete, and the writer is careful not to draw unwarranted conclusions Dr Ernest Shaw contributes a good description of the organisms met with in the female genito-urinary tract and Mr Beckwith Whitehouse devotes some 70 pages to discussing methods of examination which hardly seem necessary in a work of this character The book will only appeal to the advanced student, and more particularly appeals to the teacher and specialist Dr W W C Topley writes on the various methods of blood examination of proved clinical significance It is interesting to note that he counsels the clinician to await further developments before placing reliance on Abderhalden's test for pregnancy Dr J W Ballantyne contributes a very interesting article on Malformations of the Female Generative Organs The anomalies of the uterus would be rendered much easier to understand if it were pointed out as is done by Professor A. Keith in his book on 'Human Embryology," how all the varying forms of uterine mal-developments are met with as the normal condition in the different classes of animals This wise generalisation has been found of great assistance in teaching students Dr W Blair Bell contributes a long article on Disorders of Function which contains many most interesting statements, some of which are more convincing than others Dr G Blacker has written a very complete account of tubal pregnancy, including the subject of hæmatocele, which in the previous edition was considered, quite wrongly, apart from its main cause—viz ectopic gestation.

The rest of this volume is devoted mainly to pelvic infections Dr Carlton Oldfield contributes a good account of Septic Infections in which he lays too much stress, perhaps, upon the now somewhat old fashioned distinction between sapræmia and septicæmia. He apparently has not much faith in sera or vaccines and, we are glad to see states that it is doubtful whether operative treatment of puerperal pyæmia gives a greater percentage of recoveries than the expectant method.

Naturally in a book by so many different authors there are bound to be striking contradictions On p 553 we are told that "hysterectomy for puerperal infection should not be thought of," while on p 663 we find 'without a doubt there are cases which can be saved by surgical interference and by nothing else.' Dr T G Stevens's article on Gonorrhœa in Women is very practical and to the point and there is a good description of Tuberculosis of the Pelvic Organs by Dr Clifford White It is a pity that the editors have not insisted upon consistency in the use of terms such as tubercular and tuberculous, on p 627 both terms are used indiscriminately The latter is of course, the correct one in the circumstances The section dealing with Inflammation of the Fallopian Tubes by Dr J M Munro Kerr is essentially clinical while in that on Pelvic Cellulitis, by Dr J S Fairbairn the good work done by the late Dr Cullingworth is fully recognised. There is a short, in our opinion too short article on Syphilis in Women by Mr A. Shillitoe, of which the most interesting portion is that dealing with conceptional syphilis Two of the most original and important articles in this volume are those dealing with Streptothrix and Echinococcal Infections of the Pelvic Viscera, by Dr H C Taylor Young and Professor D A. Welsh. A short article on Nervous Diseases Associated with Morbid Conditions of the Pelvic Organs is contributed by Dr Purves Stewart

Vol. II opens with a good and well illustrated account of Diseases of the Vulva and Vagina by Mr Comyns Berkeley The article on endometritis by Professor B P Watson is the best and clearest account we are acquainted with of this often talked of but rarely met with condition and should do much to remove the confusion which is still present in the minds of so many writers on this subject. We hardly regard erosion of the cervix as worth a special section. An extremely interesting and important article one of the best in the whole work with a number of beautiful coloured illustrations is that by Dr Fletcher Shaw on Chronic Metritis Professor R G McKerron writes on Morbid Involution and Dr Hastings Tweedy on Cervical Lacerations Dr Lockyer will add greatly to his reputation as a pathologist and careful clinical observer by his article on Myomata—emphatically the best account of these tumours to be found in any text-book. In devoting, however, some 80 pages to the engrossing but not very important subject of adenomyomata he has allowed his enthusiasm to overcome his sense of proportion This section is rather of the

Medical Societies.

MEDICAL SOCIETY OF LONDON

President's Address —A Discussion on War Bread and its Effects on Health

A MEETING of this society was held on Oct 8th, when Sir **StClair Thomson**, the President, delivered an address on the Founder and the Foundation of the Medical Society

Dr **Robert Hutchison** and Dr **E I Spriggs** introduced a discussion on War Bread and its Effects on Health Dr **Hutchison** said that before discussing the effects of war bread on health it was necessary to know something of its composition The wheat berry consisted of three parts—the pericarp, germ, and endosperm In making ordinary white (pre war) flour only about 70 per cent of the wheat berry was used, the germ and pericarp being entirely discarded and used mainly for fodder In order to economise wheat it was now compulsory for millers to extract 80 per cent of the wheat berry as flour, and some of the pericarp and germ was included This Government regulation (G R) flour was the basis of war bread Chemically such flour was richer in every constituent except starch than wheat flour, and in particular it was richer in vitamines and phosphorus The question of its absorbability as compared with white flour was still *sub judice*, but there was no reason to suppose that it was inferior in this respect to white flour provided it were finely ground War bread, however, was not always made from G R flour only The addition of other cereals (maize, barley, rice, oats) up to certain limits was allowed The proportion of these added by different millers varied, and it had been found impossible to standardise the flour for the whole country None of the added cereals, however, could be regarded as injurious, and all were valuable foods Maize had come in for most popular criticism, but if properly ground there was no harm in it, and much of the hostility to it was due to prejudice As regards the bread, it must be recognised that it was impossible to prepare from the present flour a bread which had the same *æsthetic* qualities as pre war bread The darker colour was of no importance, but the relatively lower proportion of gluten, especially when other cereals were added, caused the bread to be less porous This drawback would become less as bakers acquired more experience with the flour As regards its effect on health, it seemed certain that there was nothing *chemically* injurious in war bread, indeed, it was superior from a chemical point of view to white bread Any ill effects could only be due to its *mechanical* properties (presence of grit, doughiness, &c), and could only affect the digestive organs The quality of the bread produced in different parts of the country, and even by different bakers, varied greatly in these respects, but from fairly wide inquiry there was no real evidence of any serious disturbance of digestion by the bread in the great majority of individuals It must be remembered that patients were apt to find in the war bread a convenient explanation of any disturbance of health for which they could not otherwise account In cases in which the bread seemed to disagree the effect of toasting and more thorough chewing should be tried The speaker had not himself seen any patient in whose case he was convinced that the bread had affected the digestion unfavourably

Dr **Spriggs** said that he had not found it necessary to order white bread for the patients in Duff House, although there was always a good number of sufferers from digestive complaints The war bread was, however, much better in some districts than in others, and their experience was, perhaps, fortunate The complaints which followed the measures taken by the Government to make good the lack of wheat by the use of other kinds of corn arose from several reasons The change in flavour was one reason Another one was the lack of skill and experience in making the bread with the new kinds of flour Further the mass of our people did not realise before the war that the cereals given to animals were good human foods, and did not know that by eating oats barley, or maize ourselves we could get from them many times the food value that was obtained by turning them first into animal food. He referred to the figures of Professor T B Wood, who calculated that of nearly 17 million tons of various kinds of corn used in this country before the war only 5 millions went for human food This was less than the average production of home grown corn, which amounted to 6½ millions tons Dr Spriggs said that he had advocated the use in home-made bread of a mixture of barley flour or meal, oatmeal, rice, or maize, in the proportion of one part of the meal to two parts of wheat flour or war flour This was a higher proportion of other cereals than millers were using at present (Examples of these different kinds of bread were shown to the meeting and tasted by the members Breads were also shown in which the added cereal had been boiled before mixing with the flour, making a spongier loaf) In order to compare the digestibility of such bread with that made from wheat flour experiments had been made by Mr A. B Weir, B Sc., chemist at Duff House, and himself The subject was a healthy young man who took a mixed diet containing the same foods and in the same quantities every day, each article being weighed or measured accurately The diet was was follows —Breakfast Eggs, butter, bacon, marmalade, cocoa, milk Dinner Fillet of beef, potato, cabbage, rice pudding, tinned pears, butter, cream, black coffee Tea Butter, jelly, milk, cocoa Supper Clear soup, haddock butter, cheese, coffee, milk With this a loaf of bread weighing about a pound was eaten daily The bread was composed of two thirds of white flour and a third of the meal or flour to be tested, and was made as described in Chapter IX of "Food and How to Save it."[1] These breads were compared with bread made from white flour alone, also with a war bread containing 10 per cent barley and 10 per cent maize All the breads were palatable and were preferred by the subject to baker's bread, with the exception of that made with maize, the proportion of which (33 per cent) was too high for making nice bread The war bread, which contained 10 per cent of barley and 10 per cent of maize, was thought to be one of the nicest. Each experiment lasted three days The flours were analysed separately The other foods were all minced, mixed together, and analysed The excreta for each three days were collected and their composition determined The results were given to the meeting and showed that, although there were differences in the amount of protein, carbohydrate, and fat assimilated, yet the variations were not of importance, the total amount of foodstuff assimilated when expressed in calories being almost the same in each experiment—namely between 95 and 96 per cent of the food value eaten The experiments demonstrated that bread composed of mixed cereals in the proportions recommended was palatable and, in this subject, proved as nutritious as white bread

Professor W H **Thompson** adviser to the Ministry of Food, said that it was important to get our protein food from a number of sources, because all proteins were not "adequate" for both growth and maintenance Even maize had about one third of its protein of the adequate type He thought that much of the trouble was due to ignorance in milling and baking In the early days millers were not fitted out to grind maize to a sufficient degree of fineness Observations were now being carried out which he hoped would enable all that difficulty to be overcome Samples of bread complained of had been sent to the Ministry of Food but in no case could anything be found wrong except the colour

Dr E **Kingscote** said that he had been in North Italy before the war, where a large part of the community lived altogether on maize many having no other food but they were well nourished and healthy He thought that the admixture of two flours might be the cause of the difficulty The grinding of the maize was not equal to the grinding of the wheat, and in baking each required a different amount of time to arrive at perfect cooking

Sir **StClair Thomson** said that the important matter of bread did not escape Lettsom's attention It was gathered from his writings that the price of the quartern loaf in 1774 was 8*d* but by 1800 he wrote that the quartern loaf was 1*s* 6*d*, "a sum truly oppressive to the poor" With our present-day quartern loaf at only 9*d* after three years of world war our population might take courage by seeing what our forefathers had to endure in the Napoleonic struggles In 1774 Lettsom, amongst his numerous essays printed one entitled "Hints respecting a Substitute for Wheat Bread" The substitute he warmly recommended was the fine flour of Indian corn to be mixed with that of wheat in equal proportions He added that, if rightly managed the colour would be about the same as the standard wheaten bread and about 2*d* in the quartern loaf cheaper than the fine wheaten when that might be at 8*d* per quartern After insisting on the great nutritive value and the agreeable sweet flavour of maize, he wrote that some, indeed, did not so easily reconcile themselves to it, which often arose from the mismanagement of grinding the corn or baking the bread The bakers, he said, had not acquired the best method of *mixing* and preparing it with wheat flour, and as to the grinding, he advised that the millstones should first be set so wide as but just to burst the thick or farinaceous part of the grain, which should then be passed through a sieve so as to separate the part of the interior edge of the grain composed of a ligneous spongy substance the middle of which was of a dark brown colour and of a bitter taste, which, if ground into the flour, gave it a disagreeable flavour When this deleterious part had been separated on the sieve the remainder should be ground with the stones set so as *to render it sufficiently fine* Lettsom also suggested the use of potatoes as a partial substitute for bread, and recommended the use of one-fourth of potatoes with the remainder of flour He pointed out that if a little ground rice were added the bread was prevented from crumbling, a matter of consequence in a large family

The New System of Gynæcology Edited by THOMAS WATTS EDEN, M D Edin, F R.C S Edin. F R C P Lond., Obstetric Physician Charing Cross Hospital, Surgeon, Chelsea Hospital for Women and CUTHBERT LOCKYER, M D B S Lond, F R C S *Eng* *F R C P* Lond, Obstetric Physician to Out-patients, Charing Cross Hospital, Surgeon to In patients, Samaritan Free Hospital In three volumes With numerous illustrations in colour and black and white London Macmillan and Co 1917 Price £6 6s

THIS work is really a second edition of the 'System of Gynæcology published in 1906 in association with Clifford Allbutt s System of Medicine. We quite agree with the editors when they maintain that the gynæcologist is a surgeon rather than a physician, but the best combination is that of physician and surgeon which exists when he practises both obstetric medicine and gynæcological surgery, as he does in most of the larger hospitals in this country We do not believe in the divorce of gynæcology from obstetrics The gynæcologist certainly should have an acquaintance with the diseases of the kidney rectum, and bladder but we hardly think that diseases of the breast fall within his province, nor do we believe that the majority of gynæcologists treat these diseases. In our opinion, therefore the editors have been ill-advised to *burden* an already large book by the addition of sections dealing with these surgical affections. The specialist who wishes to study the diseases of these organs will not refer to a treatise on gynæcology he will consult rather a treatise on surgery, and in this he would be showing his wisdom The result of the inclusion of these sections is three volumes where two might have been sufficient and a considerable increase in the cost of the book. No doubt the sections on general surgery which have been included are very good as far as they go but naturally, they cannot be so full as they might, and probably would be in a System of Surgery For these reasons we shall make little reference to them although several of them are of great merit.

The work has been issued in three *volumes* containing in all some 2507 pages The format, printing and paper are a great improvement on the original edition, and the whole is a most readable System The first section in Vol I is a good, but too short account of the Anatomy of the Pelvic Organs by Professor Elliot Smith and Dr J S B Stopford We wish that the editors had allowed them more space. In the second chapter Miss A. L McIlroy discusses the Physiology of the Female Reproductive Organs She regards the luteal cells as the undischarged follicle cells a view in direct contradiction to that expressed by Dr Lockyer and Dr H Williamson in other parts of the book. The section is good and complete, and the writer is careful not to draw unwarranted conclusions Dr Ernest Shaw contributes a good description of the organisms met with in the female genito-urinary tract and Mr Beckwith Whitehouse devotes some 70 pages to discussing methods of examination which hardly seem necessary in a work of this character The book will only appeal to the advanced student, and more particularly appeals to the teacher and *specialist* Dr W W C *Topley writes on* the various methods of blood examination of proved clinical significance It is interesting to note that he counsels the clinician to await further developments before placing reliance on Abderhalden s test for pregnancy Dr J W Ballantyne contributes a *very interesting* article on Malformations of the Female Generative Organs The anomalies of the uterus would be rendered much easier to understand if it were pointed out as is done by Professor A. Keith in his book on 'Human Embryology," how all the varying forms of uterine mal-developments are met with as the normal condition in the different classes of animals This wise generalisation has been found of great assistance in teaching students Dr W Blair Bell contributes a long article on Disorders of Function which contains many most interesting statements, some of which are more convincing than others Dr G Blacker has written a very complete account of tubal pregnancy, including the subject of hæmatocele, which in the previous edition was considered, quite wrongly, apart from its main cause—viz, ectopic gestation

The rest of this volume is devoted mainly to pelvic infections Dr Carlton Oldfield contributes a good account of Septic Infections, in which he lays too much stress, perhaps, upon the now somewhat old fashioned distinction between sapræmia and septicæmia. He apparently has not much *faith in sera or vaccines* and we are glad to see states that it is doubtful whether operative treatment of puerperal pyæmia gives a greater percentage of recoveries than the expectant method

Naturally, in a book by so many different authors there are bound *to* be striking contradictions On p 553 we are told that "hysterectomy for puerperal infection should not be thought of" while on p 663 we find "without a doubt there are cases which can be saved by surgical interference and by nothing else." Dr T G Stevens's article on Gonorrhœa in Women is very practical and to the point, and there is a good description of Tuberculosis of the Pelvic Organs by Dr Clifford White It is a pity that the editors have not insisted upon consistency in the use of terms such as tubercular and tuberculous, on p 627 both terms are used indiscriminately The latter is of course, the correct one in the circumstances The section dealing with Inflammation of the Fallopian Tubes, by Dr J M Munro Kerr, is essentially clinical while in that on Pelvic Cellulitis, by Dr J S Fairbairn the good work done by the late Dr Cullingworth is fully recognised. There is a short, in our opinion too short, article on Syphilis in Women by Mr A. Shillitoe, of which the most interesting portion is that dealing with conceptional syphilis Two of the most original and *important* articles in this volume are those dealing with Streptothrix and Echinococcal Infections of the Pelvic Viscera, by *Dr* H C Taylor Young and Professor D A. Welsh. A short article on Nervous Diseases Associated with Morbid Conditions of the Pelvic Organs is contributed by Dr Purves Stewart

Vol II opens with a good and well illustrated account of Diseases of the Vulva and Vagina by Mr *Comyns Berkeley* The article on endometritis by Professor B P Watson is the best and clearest account we are acquainted with of this often talked of but rarely met with condition, and should *do much to remove* the confusion which is still present in the minds of so many writers on this subject. We hardly regard erosion of the cervix as worth a special section. An extremely interesting and important article, one of the best in the whole work with a number of beautiful coloured illustrations is that by Dr Fletcher Shaw on Chronic Metritis Professor R G McKerron *writes* on Morbid Involution and Dr Hastings Tweedy on Cervical Lacerations Dr Lockyer will add greatly to *his* reputation as a pathologist and careful clinical observer by his article on Myomata—emphatically the best account of these *tumours* to be found in any text-book. In devoting, *however* some 80 pages to the engrossing but not very important subject of adenomyomata he has allowed *his* enthusiasm to overcome his sense of proportion This section is rather of the nature of a critical essay and contains the names of numerous writers without references Lists of names are useless to the student, and annoying to the expert when unaccompanied by references so that he may without undue difficulty refer to the originals Dr R W Johnstone contributes an interesting account of Sarcomata of the Uterus The section on Cancer of the Uterus by Professor T Wilson is a mine of information We are afraid, however, that the author's pathology will tend to increase the confusion which surrounds at present this subject His statements are hardly borne out by his illustrations, so far as it is possible for the reader to draw any conclusions from them as to the correctness of the statements made We do not fancy that Professor Wilson will find much support for his views among pathologists, nor do we regard them as correct Of the excellence of the article as a whole there can be no question, and the discussion on treatment will be read by all gynæcologists with great interest It is the more valuable because the writer is able to contrast in an authoritative manner the older with the more modern results of operative interference Professor H J Teacher's article on Chorion Epithelioma Malignum is as might be expected very full and good Professor W W Chipman writes a reasoned and effective account of Backward Displacements of the Uterus, in which he lays appropriate stress upon the large part played by some degree of prolapse in these cases, and which includes a well balanced discussion of operative treatment In his account of Prolapse of the Uterus Dr W E Fothergill who has changed his views, maintains if the surgeon can do vaginal work well no abdominal operation should be performed for this condition. He is very optimistic about the results of such operations, and in this he differs from most writers We are glad to see that he condemns hysterectomy for uncomplicated prolapse The section on Inversion of the Uterus is contributed by Professor W C Swayne Dr Lockyer, in the article on cysts and tumours of the Fallopian tubes, alludes to the embryonic tubules regarded by Professor A Keith as the homologues of the rete testis We can find no allusion to this interesting question either in the index or in the article on the anatomy and development of the pelvic organs This volume is completed by a very clear and good account of Tumours of the Ovary by Dr H Williamson and Dr J D Barris

Vol. III contains articles on Diseases of the Breast by Mr C C Choyce, on the Vermiform Appendix, by Mr H J Paterson, on Methods of Examination of the Urethra and Bladder, by Mr J Thomson Walker, on Diseases of the Rectum, by Mr J P Lockhart-Mummery, and Intestinal Complications in Gynæcological Surgery, by the late Mr Scott Carmichael Mr W Gilliatt writes on Affections of the Urinary Tract, and Dr Eardley Holland on Hernia in Women A good article on the Technique of Gynæcological Operations is contributed by one of the editors, Dr Eden There is a short but clear section dealing with anæsthetics, by Dr F S Rood, and this is followed by two articles of considerable interest, by Dr A. Donald and Dr A. E Giles respectively, on ovariotomy and hysterectomy Dr Giles's article is a particularly good and interesting one, as it includes some valuable statistics and a summary of the history of the development of the operation Surgical operations on the gravid uterus are described by Professor Munro Kerr with commendable brevity and clearness We notice he does not think that extraperitoneal Cæsarean section will survive unless it is proved that the cicatrix in the lower uterine segment is stronger than one in the upper part of the body of the uterus Professor Howard Taylor's section on vaginal cœliotomy is good but gives one the impression that his advocacy of this method is of a somewhat half hearted nature, and, if this is so we are in agreement with him Professor J B Hellier deals with fistulæ in the female pelvic organs Mr Victor Bonney describes the various minor gynæcological operations, and Professor Franklin Martin writes a most instructive chapter termed the After treatment of Gynæcological Operations (should it not be of patients after such operations?) The articles on Röntgen Rays and Radio-Therapeutics in Gynæcological Practice would be of greater value if they were a little more up to date

It is impossible to do complete justice to a work of this scope in a review We have no hesitation however, in saying that this "System" does the greatest credit to all concerned in its production and it is the best and most complete work on gynæcology which has appeared so far in the English language The illustrations are many of them of great beauty and extremely well reproduced, and great credit is due to the artists who drew them We hope, however, when the book reaches a second edition that the editors will improve it by adding a proper bibliography to each section by enlarging and revising the index and equipping each volume with a general index, and by omitting all the articles on purely surgical subjects In this way the size of the work might well be reduced and at the same time its cost, which is excessive

Acute Appendicitis Practical Points from a 20 Years Experience By C HAMILTON WHITEFORD M R C S, L R C P Lond, late Specialist in Surgery, Military Hospital, Devonport, Author of 'Anæsthetics in Surgery," &c London Harrison and Sons 1917 *Pp* 72. Price 4s net

IN this little book the author has put together the main facts relating to the diagnosis and treatment of acute appendicitis In the diagnosis the several symptoms are discussed seriatim, so that the reader is made to understand their relative value The indications for operation are also clearly given The author is in favour of immediate operation in all cases but he limits the operation to incision and drainage if an abscess is present and the appendix does not present itself, while if any diffuse peritonitis is present and the patient is collapsed no attempt is made to remove the appendix even if it has not ruptured The book is certainly likely to be useful, and with nearly all the opinions expressed we fully agree but it does not contain sufficiently detailed instructions For instance, the author, with good reason, praises highly the "Murphy drip," or protoclysis, and he mentions many useful points in connexion with it, but we feel sure that no one unacquainted with the method would be able to carry it out from the instructions contained in this book We should be interested to learn why the author writes "appendiceal' and "nossil."

The Biology of Twins (Mammals) By HORATIO HACKETT NEWMAN The University of Chicago Science Series With plate and 65 figures in text University of Chicago Press, Chicago, Illinois 1917 *Pp* 185 Price $1 25

THIS little book contains an excellent account of the curious and very special phenomenon of polyembryony in certain armadillos The condition has been known to zoologists for many years, but it is due to the labours of M Fernandez, J T Patterson, and the author of this volume that it has been placed of late upon a firm basis of ascertained fact As a connected account of this curious phase of reproduction the work is a useful one to the biologist Some account is also given of the production of twins in man, and the work of Wilder is presented with some fullness, but it cannot be said that this portion of the book reaches the level attained by the chapters on armadillos Among the list of "authors" at the end of the volume one notes the name of P J Barnum This is obviously intended for the late Mr P T Barnum, who is included as an authority on human twins on the strength of having exploited the Siamese twins On the other hand, one looks for the name or the work of Ballantyne in vain

The subject of twins among the offspring of cattle is dealt with in a far less satisfactory manner Here the work of F R Lillie is largely followed and the "hormonic theory' of the formation of the freemartin is upheld In assuming that the freemartin is a female with certain male characters the author throws aside the work of Berry Hart and others in a manner which is not in accord with the best traditions of science

AT a recent meeting of the Plymouth Housing Committee it was stated that 2000 new houses for working men were required at once, and at the conclusion of the war an additional 1000 would be necessary

CHOLERA IN THE PUNJAB —Cholera has occurred in the Punjab chiefly amongst persons returning from a visit to Hardwar, the holy places on the Ganges In the majority of cases there has been no difficulty in preventing the spread of the disease, but an outbreak in the Umballa district is giving cause for anxiety, as 69 cases and 38 deaths have occurred there

GALYL

Recurrent Fever
SYPHILIS
Frambœsia
Sleeping Sickness

3000 Injections (INTRAVENOUS) of GALYL were given in one of our Service Hospitals.

"No case has given the slightest cause for anxiety, and the clinical results are very satisfactory"

—*Staff-Surgeon's Report*

IMPROVED INTRAMUSCULAR INJECTION.

The GALYL is in the form of a Sodium Salt in a weak solution of Glucose This is much easier to use and more rapidly absorbed than the oily emulsion It is in every way identical with the intravenous—efficacy dose, price, &c only differing in administration

Thorough and exhaustive tests in various parts of the Kingdom have proved it to be equal in every way with the intravenous, moreover, patients may resume and continue their occupations without inconvenience after injection of Intramuscular GALYL

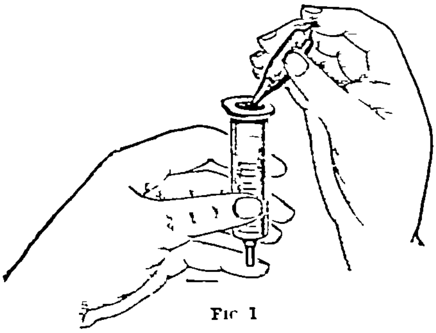

FIG 1

The technique is simple Fig 1 shows the ampoule of GALYL being emptied into the syringe barrel—the needle is now fixed on the neck of the syringe and the plunger inserted into the barrel The injection is then ready for administration

The results are excellent both immediate in the clearing up of evident lesions and ultimate as proved by the Wassermann test Personally I have used this preparation in over 400 injections with the best results and without the slightest mishap or inconvenience to the patient"

Yours faithfully

Dr ———

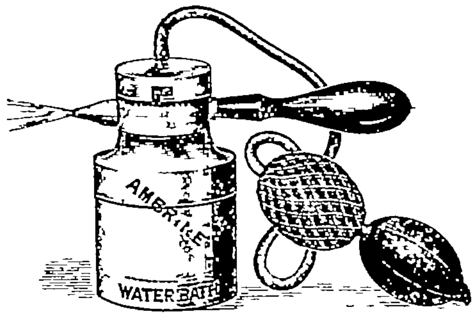
A Great Advance in the Treatment of **BURNS**—*Slight or Severe*

AMBRINE

Ambrine is *the only Authorised preparation* of Dr Barthe de Sandfort
We are compelled to state this as there are various imitations

Ambrine forms a dressing which INSTANTLY alleviates pain—promotes rapid healing—forms a sure protection against infection of the wound—can be removed without pain, hæmorrhage, or injury to the newly-formed tissues The healing leaves no scars or contractions

The most efficient means and method of ensuring active Hyperthermal-Therapy to the practical treatment of Rheumatism, Gout, Arthritis, Varicose Ulcers, and similar affections



May be applied with camel hair brush but our specially designed spray greatly facilitates the application of Ambrine especially in the case of deep wounds or extensive surfaces

THE LANCET, June 10th, 1916 —

THE VALUE OF AMBRINE IN THE TREATMENT OF WOUNDS

"Attention is being drawn to the remarkable success of the Ambrine Wax treatment now being used at the Hôpital St Nicolas at Issy les Moulineaux for burns, frozen feet and all wounds where the tissues have been so damaged as to exact great length of time and considerable disfigurement in their restitution by the usual means. The Minister of War in reply to the Deputy M Mons as to why in view of the marvellous results obtained by treating burns and frost bites with Ambrine at the Hopital St. Nicolas all the soldiers suffering from such wounds were not sent there, stated that this was being done as far as possible .."

Rational Treatment of CONSTIPATION.

OPOLAXYL

By the double action of secretions and peristalsis

Opolaxyl is a combination of the secretions of the liver (biliary), pancreas and intestines, with vegetable extracts of a non-drastic nature

It combines all the secretions to correspond to nature's therapy and promotes a flow of bile and glycogen

It is a normal regulator of the gastro-intestinal functions, consequently it improves the metabolic changes of the entire organism

Opolaxyl does not lose its efficacy by prolonged use, its effect is gentle and constant with the least irritation It is not merely purgative, it stimulates the defective organs and revives the normal equilibrium, it has a lasting effect by reason of it rebuilding the organs thus correcting diminutional function

Opolaxyl is put up in small size tabular form and should be swallowed without crunching at bedtime or before breakfast

DOSE—For obstinate constipation 2 or 3 tablets, afterwards 1 tablet every 3 or 4 days for a month

Phylacogen Therapy

Phylacogens are sterile aqueous solutions of metabolic substances generated by bacteria grown in artificial media, and from which the bacteria have been carefully removed by filtration

RHEUMATISM PHYLACOGEN

Has proved remarkably effective in the treatment of various forms of rheumatism not due to specific infection, also of arthritis, sciatica, lumbago, chorea, neuritis, iritis, &c Numerous cases of arthritis deformans have been benefited, many of which had resisted all other methods of treatment for 5, 10, and even 15 years

GONORRHŒA PHYLACOGEN

Specially indicated in chronic gonococcal infections and their sequelæ, such as gonococcal arthritis and iritis, prostatitis, epididymitis, vesiculitis and cystitis in the male, and vaginitis, cervicitis, endometritis and salpingitis in the female In cases of acute urethritis treatment requires to be supplemented by germicidal injections, such as argentide or protosil

MIXED INFECTION PHYLACOGEN

The hypodermic administration of Mixed Infection Phylacogen is indicated in all infections, acute or chronic, mild or severe, in which no specific micro-organism is found to be predominant, notably in surgical infections, abscesses, puerperal sepsis, diseases of the skin—acne, eczema, impetigo, sycosis, diseases of the nose and ears—suppurating antrum, otitis media, rhinitis, catarrh, &c

PNEUMONIA PHYLACOGEN

Indicated in the treatment of pneumonia or of any pathological condition caused by the pneumococcus

Recent reports from English practitioners show that it is rarely necessary to give more than four injections of ½ to 1 c c each before the temperature falls Of 21 cases reported during three months there was only one death—a young man in whom the pneumonia was complicated with mitral disease

ERYSIPELAS PHYLACOGEN

The hypodermic administration of Erysipelas Phylacogen is indicated in the treatment of erysipelas, the acute infectious disease caused by streptococcus erysipelatis

Further particulars, with Clinical Reports, will be found in our booklet entitled "Phylacogen Therapy," which will be sent to any Medical Man on request

The Phylacogens are supplied in 10 c c phials, each containing from 4 to 6 doses, and in cases of 5×1 c c ampoules

PRICES

Phials of 10 c c, 11/8 each

Cases of 5 × 1 c c ampoules, 7/- per case

Subject to 10 per cent discount to Medical Men

Prophylaxis in Venereal Disease.

As we announced last week, the question of the artificial prophylaxis of venereal disease has been discussed recently by the National Council for Combating Venereal Diseases, and a special meeting of the Council will be held on Monday next, Oct. 15th, at the house of the Royal Society of Medicine, and will have before it a resolution, the fate of which is awaited with deep attention by the medical profession and the public. The resolution which will be submitted to the National Council by the Executive Committee of that body runs as follows:—

> In view of the public attention now directed to the whole subject of prophylaxis, the Executive Committee, after careful consideration, is not prepared to depart from its original position, in which, in accordance with the spirit of the Royal Commission's Report, it refrained from recommending the adoption of prophylaxis—i.e., the provision of outfits to men before sexual indulgence. The committee strongly urge the importance of the making of arrangements for the early treatment of venereal disease even before the outset of symptoms.

Will the National Council remain of the opinion expressed in the resolution?

The whole question of the artificial prophylaxis of venereal disease is thus introduced *for debate* by the National Council, but in considering that question we are now regarding generally the health of the public in the fourth year of war, and especially the condition of our Imperial Armies, both as fighting men and as future citizens. We are not blind to the religious forces which coerce the vote of some consciences on all sexual matters, nor do we write ignoring the claims made by many public-spirited and enlightened women for an equality of treatment between the two sexes in regard to circumstances which surround mutual actions. These things have due weight with all who desire the right. They will certainly receive earnest attention from the National Council when considering the resolution of the Executive Committee. We do not discuss them here because all that is to be said along the two lines indicated has been said so often that our readers are familiar with the arguments and know exactly why the National Council has adopted the line of policy indicated in the resolution. Attention is called now to the fact that the facilitation for men of artificial prophylaxis before sexual indulgence has been deliberately excluded from the scheme devised by the National Council. The Council, in declining to recommend or to take cognisance of any steps of the kind, has followed the lead given to it by the Report of the Royal Commission on Venereal Diseases the translation of whose conclusions into law was the reason for the creation of the Council. The Executive Committee urge upon the National Council the importance of the making of arrangements for the early treatment of venereal diseases, even before the onset of symptoms, but they do not now, any more than in the past, advise any departure from the original line taken up with regard to artificial prophylaxis. They will expect to be asked to support the policy which they continue to advocate by facts, inasmuch as facts are being brought forward to make it doubtful if their policy is now the best, whatever it may have been two years ago. And it would probably be better if preventive treatment, for purposes of the discussion that must ensue, were divided into three headings, and that under each the circumstances of the civilian population were regarded as differing from those of the Navy and Army. The three headings are (1) artificial prophylaxis; (2) early preventive treatment; and (3) the control of loose women in certain areas. It seems to us clear that the preventive treatment in relation to venereal disease among troops should start earlier than it does now—that is to say, that the form of prophylaxis alluded to in the report of the Executive Committee should no longer be refrained from. We published last week a brief account of the measures taken in great centres in India and Australia to enlighten the public generally as to the incidence of venereal disease, and especially to protect the soldiers; and it is largely in the interest of the Colonial contingents of our Army that the National Council for Combating Venereal Diseases may be inclined to depart from its original position. The Canadian, Australian, and especially the New Zealand troops have suffered greatly from venereal disease, and, with regard to the last, we have been furnished with figures—supplied also, we understand, to New Zealand newspapers—which almost justify the phrase employed in the communication that "London is the plague spot of the world." There can be no doubt that the feeling among numerous officers of our Colonial troops is that the facilitation of artificial prophylaxis is necessary for the safety of their men, while many are convinced that the control of loose women would greatly increase the fighting strength, and would annul the risk that the soldiers may carry back to their homes hereditary disease as well as the glory of having fought for their country. To these feelings every consideration is due; and, if the views expressed can be supported statistically, the country at large will hold that the National Council for Combating Venereal Diseases have a responsibility put upon them by the war that was not upon them when they were created to carry out the valuable conclusions of the Royal Commission.

We are in the face of military facts: all men are wanted, and venereal disease prevents a certain proportion of them from responding to the call. Measures might quite sensibly be taken now which would have no justification in normal times, nor would a change of attitude at such a juncture mean a permanent return to discredited social tactics. We are at this moment reconciled, with a unanimity that would have been quite inconceivable three years ago, to the distribution of bombs by aeroplanes upon German cities Does anybody believe that the spirit thus indicated is likely to remain a permanent national spirit of this country ? In the same way, we do not for a moment suppose that, if it should be found wise to day to control the action of certain women in certain military areas, or to recognise the existence of illicit coitus by instituting a system of supply to sailors and soldiers of prophylactic apparatus, we should be committed in the future to the lower state of public morals indicated by such methods These are some of the more important points which the National Council for Combating Venereal Diseases will have before them at their meeting on Monday next, and we feel sure that they will be debated frankly, and that no restraint will be put upon the expression of opinion by the allegation that to depart from a line of conduct hitherto followed is either to do ill with the illogical hope that good may come, or to display a cowardly inconsistency It requires knowledge to decide what an ill deed really is, and it requires courage to deal with facts which contravene an accepted course of procedure

◆

War Deafnesses

DURING the present war there have returned from the French front a very large number of officers and men who considered that their hearing had been damaged by gun fire or shell explosion The features of these cases differed from the familiar gunners' deafness of former times in that the damage appeared to be the result of a relatively short exposure to detonation, often to be the consequence of a single shell burst, and tended almost uniformly to recovery, sometimes sensibly complete, but in the majority of instances partial Tinnitus was not generally a prominent feature In the type case there was no visible damage. In addition to these cases there have been many of chronic or recurrent middle ear suppuration which we may put on one side, and a relatively small class with evidence of recent bursting of the membrana tympani. Within the experience of many observers these cases with manifest middle ear damage have escaped with a middle ear deafness only

The difficulties in classification and prognosis attach to the group which presents no evidence of local injury and with an apparent labyrinthine deafness, and they arise from the fact that with our present methods of testing hearing we have no sure means of distinguishing the two factors in hearing, the capacity of the peripheral instrument in the cochlea and the performance of the cortical organ of consciousness operating with this From the experience following the testing and watching of a large number of cases throughout the war, it would seem that the cortical factor may vary in intensity from a mere feebleness of concentrated attention to a total inhibition of any attention at all The more complete the inhibition, the greater the likelihood that recovery, if it takes place, will be sudden Deafness, however, rarely remains total, and the common history is that nothing at all can be distinguished for a few hours, that then hearing begins to return, but that after some few weeks it still remains defective, often more so in one ear than the other Further, some of these patients have experienced a greater or less degree of giddiness in the early stages, and some have vomited Finally there is, we believe, histological evidence that the cochlea may be extensively disorganised as the result of concussion by explosion, a condition which could hardly result in anything but total labyrinthine deafness If we put these points by the side of the fact that patients with burst membranes do not exhibit serious labyrinthine types of deafness, it is probable that there is in many cases a real labyrinthine factor in these deafnesses An interesting pair of cases, illustrating the extreme degree of suppression of cortical function, were recorded in THE LANCET of Oct 6th by Major A F HURST and Captain E A PETERS, who are to be congratulated on obtaining recoveries which might have been long delayed The employment of suggestion under light administration of an anæsthetic is well known, and in these cases the suggestion proved powerful We feel a little doubtful, however, of the desirability of the frequent use of the method, having a prejudice against any procedure which may lead in the long run to abuse, and a consequent lowering of the status of surgery We believe it likely, moreover, that any other powerful stimulus applied during the removal of the subconscious determination against hearing would have been as effective as suggestion proved The clinical points of interest seem to be the completeness of the suppression of reflex from the lower centres even in sleep, and the fact, in view of this, that the voice was not altered, showing that somewhere in the depths of consciousness there still lay hidden the appreciation of the patient's own voice As to the conclusion arrived at by Major HURST and Captain PETERS that an apparently total deafness associated with continued excitability of the posterior labyrinth is evidence of hysterical deafness, a doubt may reasonably be expressed, on the ground that two cases are quite an insufficient basis for such a generalisation, and on the further ground that cases of mild labyrinthitis occur in which there appears to be total deafness but in which the canal reflex can still be excited

The inquiry opened by Dr T B JOBSON, whose paper appears in another column, into the question of the effect of gun fire on the generality of men exposed to it and not aware of any resultant deafness, is an interesting one and worth, we think, further and much fuller pursuit At present the data appear to us to be altogether inadequate to furnish conclusions The apparent loss which Dr JOBSON found for a C2 fork, if this be a fairly heavy one, is not greater than will be found in a large proportion of average hospital patients, and appears to be largely due to the defect of training in attention, and this holds for both air and bone conduction It has further to be remembered that in any random sample of the adult population a sufficient number of really deaf ears will be present to furnish the proportion of larger defects. It would be interesting to know whether one ear, say the right, was uniformly tested before the other, and whether the tests were made singly or as the mean of several determinations. A further ground for doubting the conclusion arrived at is the general belief in the past that gun deafness is not at all an obstructive deafness, but of a purely labyrinthine type.

Annotations

"Ne quid nimis."

WOMEN AND A STATE MEDICAL SERVICE

THE subject of a Ministry of Health claimed the attention of the Medical Women's Federation at their recent conference in Manchester, and no dissent was expressed with Dr Jane Walker's view that such a Ministry was really coming and was to be welcomed in so far as it simplified the present cumbersome methods of various Government departments dealing with health matters. But a distinction was clearly drawn between such action and the merging of the personality of the general practitioner in a State Medical Service. Dr Catherine Chisholm dealt with the whole question as it affects medical women and their individual work. To the women of the country the woman practitioner has become a necessity in their lives, someone, that is, who knows the family intimately, its health, its position, and its difficulties, and who is a friend in need at times of trouble. Women are relying more on doctors of their own sex for themselves and their children, and Dr Chisholm foresees an ever increasing demand for medical women practitioners in all grades of social life. But the development of public health practice acts on the profession of medicine by women in many ways, for while such practice rivals general practice in interest, it provides posts with fixed salaries and regular hours, which may draw away numbers of women who would otherwise do general service among the people. The right solution for this perplexing situation Dr Chisholm sees in a better coöperation between the various phases of medical activity. While women should be encouraged to develop their medical work along the lines which most appeal to them, specialisation ought to follow on general experience and not commence at too early a stage in the career. The practical clinical work under the various departments of the Ministry of Health, such as maternity, child welfare and venereal treatment, should in her opinion be carried out by medical practitioners who have given evidence of special experience in these subjects rather than by whole time officers. At present these posts are often held by women with little, if any, general experience either of medicine or of life, with results which Dr Chisholm finds are disadvantageous to preventive medicine while promoting jealousy between it and clinical practice. Part time posts at all events in large centres are not open to the same objection, and if the practical encouragement of specialisation led to women of ability settling in sufficient numbers in areas where they are needed, the general public would be the gainer, and there would be a raising of the standard of the work done. On these grounds Dr Chisholm advises her colleagues in general practice to welcome the setting up of State subsidised treatment centres with laboratories attached, to be at the service of all practitioners, thus affording opportunities to the insured for specialised treatment. Women practitioners with special qualifications could then choose between private practice, or paid posts at the centres, or a combination of the two. Dr Chisholm's suggestions will command the careful consideration of the many keen women students entering the medical profession.

FUNCTIONAL CARDIAC AND PULMONARY TROUBLES ATTRIBUTABLE TO A LESION OF THE CARDIAC PLEXUS AND THE NERVES IN THE MEDIASTINUM.

AT a meeting of the Académie de Médecine of Paris M. Emile Sergent called attention to a lesion which the war has brought to light. He has observed a group of cases in which wounds of the chest are followed some time after recovery by respiratory difficulty, palpitation, and pains, and yet examination of the chest shows complete integrity of the heart, pericardium, lungs, pleuræ, and mediastinum, except perhaps for the presence on the screen of the shadow of a bullet in the region of the great vessels, in the zone of the cardiac plexus. Excluding nervous and hypochondriac patients, there remains a certain number of wounded, the reality of whose troubles cannot be doubted. M. Sergent's attention was first called to this group by the following case.

At the beginning of the war, in August, 1914, a man was wounded by a rifle-bullet which entered the chest 4 cm. above the left nipple, passed from before backwards, and lodged in the muscles of the back on the left side. After initial symptoms, such as loss of consciousness and hæmoptysis, he was considered cured and sent away convalescent. However, he continued to complain of constant oppression increased by the slightest effort, palpitation, and pains in the chest. M. Sergent saw him in November and found typical left phrenic neuralgia with immobility of the left half of the diaphragm, instability of the pulse which increased on the slightest movement, inequality of pupils (the left being in mydriasis), and preservation of the accommodation reflexes. Radioscopy showed complete integrity of the lungs, pleural cul-de-sacs, mediastinum, and movements of the heart, and confirmed the immobility of the left half of the diaphragm. There gradually developed hypertrophy of the thyroid gland with permanent tachycardia, tremor, and proptosis. Under high frequency currents and "hemato-ethyroidine," the symptoms of Graves's disease diminished at the same time as the other symptoms.

M. Sergent attributes these symptoms to lesions of the cardiac plexus and the phrenic nerve produced in the passage of the bullet. He regarded the supervention of symptoms of Graves's disease as supporting the theory which ascribes them to irritation of the sympathetic. His view was supported by 9 other cases of the same kind in which there was instability of the pulse and respiratory rhythm with constant dyspnœa, increased by the slightest effort. To these cardinal symptoms there was added in 3 cases phrenic neuralgia, inequality of pupils in 4, and symptoms of Graves's disease in 5. In all the region of the cardiac plexus was injured by a projectile which was shown either by its presence being revealed by radioscopy or by the position of its track. When the projectile is present the question of its removal arises. The surgeon must consider whether the risks of operation in such a region are not greater than those of unanimity that would have been quite inconceivable three years ago, to the distribution of bombs by aeroplanes upon German cities Does anybody believe that the spirit thus indicated is likely to remain a permanent national spirit of this country? In the same way, we do not for a moment suppose that, if it should be found wise to day to control the action of certain women in certain military areas, or to recognise the existence of illicit *coitus* by instituting a system of supply to sailors and soldiers of prophylactic apparatus, we should be committed in the future to the lower state of public morals indicated by such methods These are some of the more important points which the National Council for Combating Venereal Diseases will have before them at their meeting on Monday next and we feel sure that they will be debated frankly, and that no restraint will be put upon the expression of opinion by the allegation that to depart from a line of conduct hitherto followed is either to do ill with the illogical hope that good may come, or to display a cowardly inconsistency It requires knowledge to decide what an ill deed really is, and it requires courage to deal with facts which contravene an accepted course of procedure

---

War Deafnesses

DURING the present war there have returned from the French front a very large number of officers and men who considered that their hearing had been damaged by gun fire or shell explosion The features of these cases differed from the familiar gunners' deafness of former times in that the damage appeared to be the result of a relatively short exposure to detonation, often to be the consequence of a single shell burst, and tended almost uniformly to recovery, sometimes sensibly complete, but in the majority of instances partial Tinnitus was not generally a prominent feature In the type case there was no visible damage. In addition to these cases there have been many of chronic or recurrent middle ear suppuration which we may put on one side, and a relatively small class with evidence of recent bursting of the membrana tympani Within the experience of many observers these cases with manifest middle ear damage have escaped with a middle ear deafness only

The difficulties in classification and prognosis attach to the group which presents no evidence of local injury and with an apparent labyrinthine deafness, and they arise from the fact that with our present methods of testing hearing we have no sure means of distinguishing the two factors in hearing, the capacity of the peripheral instrument in the cochlea and the performance of the cortical organ of consciousness operating with this From the experience following the testing and watching of a large number of cases throughout the war, it would seem that the cortical factor may vary in intensity from a mere feebleness of concentrated attention to a total inhibition of any attention at all The more complete the inhibition, the greater the likelihood that recovery, if it takes place, will be sudden Deafness, however, rarely remains total, and the common history is that nothing at all can be distinguished for a few hours, that then hearing begins to return, but that after some few weeks it still remains defective, often more so in one ear than the other Further, some of these patients have experienced a greater or less degree of giddiness in the early stages, and some have vomited Finally there is, we believe, histological evidence that the cochlea may be extensively disorganised as the result of concussion by explosion, a condition which could hardly result in anything but total labyrinthine deafness. If we put these points by the side of the fact that patients with burst membranes do not exhibit serious labyrinthine types of deafness, it is probable that there is in many cases a real labyrinthine factor in these deafnesses An interesting pair of cases, illustrating the extreme degree of suppression of cortical function, were recorded in THE LANCET of Oct 6th by Major A F HURST and Captain E A PETERS, who are to be congratulated on obtaining recoveries which might have been long delayed The employment of suggestion under light administration of an anæsthetic is well known, and in these cases the suggestion proved powerful We feel a little doubtful, however, of the desirability of the frequent use of the method, having a prejudice against any procedure which may lead in the long run to abuse, and a consequent lowering of the status of surgery We believe it likely, moreover, that any other powerful stimulus applied during the removal of the subconscious determination against hearing would have been as effective as suggestion proved The clinical points of interest seem to be the completeness of the suppression of reflex from the lower centres even in sleep, and the fact, in view of this, that the voice was not altered, showing that somewhere in the depths of consciousness there still lay hidden the appreciation of the patient's own voice As to the conclusion arrived at by Major HURST and Captain PETERS that an apparently total deafness associated with continued excitability of the posterior labyrinth is evidence of hysterical deafness, a doubt may reasonably be expressed, on the ground that two cases are quite an insufficient basis for such a generalisation, and on the further ground that cases of mild labyrinthitis occur in which there appears to be total deafness but in which the canal reflex can still be excited

The inquiry opened by Dr T B JOBSON, whose paper appears in another column, into the question of the effect of gun fire on the generality of men exposed to it and not aware of any resultant deafness, is an interesting one and worth, we think, further and much fuller pursuit At present the data appear to us to be altogether inadequate to furnish conclusions The apparent loss which Dr JOBSON found for a C2 fork, if this be a fairly heavy one, is not greater than will be found in a large proportion of average hospital patients, and appears to be largely due to the defect of training in attention, and this holds for both air and bone conduction It has further to be remembered that purpose of more exactly defining a colour—thus a yellow colour is frequently described as lemon or canary, a red colour as brick or claret—our comparisons are made to objects whose hues are fixed by mathematical laws In the case of sound and light we have a comparatively narrow scale There are seven primaries as seen in the spectrum and in the range of notes from A to G It is difficult at present to determine whether smells may be similarly brought into a system of scales or octaves Such a system, however, has been suggested in the construction of perfumes Many years ago Dr Septimus Piesse, for example, set out a series of odours in parallel with a musical scale and showed how it was possible to make a bouquet correspond to a chord Perfumers thus speak of a gamut of odours, placing the name of the odour in a position corresponding to its effect upon the olfactory sense in the order of the amplitude of vibration The gamut of odours thus constructed certainly suggests a law of octaves, for we find that, according to Dr Piesse's ingenious arrangement, at the lower end of the scale the note B corresponds with clove, while the octave B above gives stocks and pinks and the higher octave B cinnamon The keen sense of smell will recognise a similarity of odours here just as the musician recognises the repetition of a note in octaves The fact that some persons associate certain colours with smells, and that others speak of certain musical notes as suggesting corresponding colours, is interesting sentimentally but not scientifically

HEALTH OF BELFAST IN 1916

OUR Belfast correspondent writes —

'The annual report for 1916 of Dr W H Bailie, medical officer of health of Belfast, just issued, tells us that the death rate (calculated on a population as estimated by the Registrar General to the middle of the year of 390 000) was 16 7, which is the lowest ever recorded in the city The birth rate was 24 1—a decrease of 1 2 per 1000 as compared with the previous year—and is the lowest ever recorded In 1890, when it was highest, the birth rate was 35 5 per 1000 and there has been a steady drop since 1896, when it was 34 5 In 1895 with a population of 295,000, there were 9772 births, while in 1916, with a population of 390 000, the births were 9415, or a population of almost 100,000 more has yielded 357 fewer children Of the deaths of children under one year, 36 8 per cent were due to congenital debility, 17 3 per cent to diarrhœal diseases 15 9 per cent to bronchitis and pneumonia, 8 2 per cent to whooping-cough and measles, and 4 8 per cent to convulsions these being the principal causes of death It is satisfactory to note that the infantile mortality rate—113 deaths per 1000 births—shows a decrease of 24 per 1000 on 1915 Of the 6496 deaths registered during the year 1916 there were from diseases of the respiratory system 1176 (pneumonia 506 others 670), and from tuberculous diseases 1131 (phthisis 830, other forms 301), from cancer 332, from diarrhœa 236 (198 under two years of age, and 38 two years of age and upwards) from measles 191 from violence 147 from whooping cough 120 and from scarlet fever 52. There were 1067 deaths (that is, 16 4 of total deaths registered) under one year—namely, about one sixth of the deaths in Belfast in 1916 were due to infantile mortality Of the 1467 cases of infectious diseases notified, 969 were scarlet fever, and 650 deaths—a mortality of 1 7 per 1000 of the population—were caused by zymotic diseases (seven principal zymotic diseases) Out of the immense number of cases of scarlet fever 969, there were 52 deaths while 191 deaths were registered from measles and 120 from whooping cough It is noteworthy that the deaths from measles were 12 more than the notifications, and from whooping-cough 81 more these facts indicating the uselessness of any system of voluntary notification Pulmonary phthisis caused 830 deaths (that is 2 1 per 1000, an increase on the rate of the previous year, which was 2·0) yet owing to the absurd way the Tuberculosis Prevention (Ireland) Act 1908, was drawn, there were only 69 notifications of patients suffering from tuberculosis of the lung in 1916"

THE HEALTH OF THE ARMY IN 1913

AT the present time of writing the year 1913 seems to be a long way off, and what was of importance then can hardly be regarded with much interest under the circumstances of to-day There are certain duties, however, that have to be carried on whatever happens, and amongst these the continued preparation, collection, arrangement, and publication of statistical data may be reckoned as not the least important, though the difficulties to be overcome in the way of depleted staff and increased work—this often of a most urgent and peremptory character—must be considerable We feel that an acknowledgment is due to the War Office authorities for having prepared and issued the Report on the Health of the Army for 1913, which bears the marks of clearness, conciseness, and completeness that have distinguished its predecessors for more than half a century, and have made them statistical models for the corresponding publications of other Governments throughout the world

The volume now under notice will always have a special statistical interest as showing the health conditions of the Army immediately before the outbreak of the war—an epoch of profound historical importance

During the year 1913 the ratio of admissions to hospital was somewhat in excess of the corresponding figure for 1912, but the ratios for death constantly sick in hospital and invaliding were less than in any previous year The following table summarises the most important points in ratios per 1000:—

	Admissions	Constantly sick	Deaths	Invaliding
1889–1893	997 3	69 85	9 03	15 36
1899–1908	700·9	40·52	6 65	17 56
1908–1912	473 5	26 39	3 80	8 88
1912	426 3	23 72	3 26	8·25
1913	437 7	23 53	2 81	7 68

According to the system that has been in successful operation for some years men suffering from certain trivial affections are treated in barracks instead of being admitted to hospital If these slight cases (8 68 per 1000 constantly sick) be added to the hospital cases the total ratio comes to 32·21 a slight increase on the ratio (31 59) for 1912

The total strength of the Army amounting to 210 356 warrant and non-commissioned officers and men may be divided into three groups[1] half of the troops (105 659) were serving at home, the remainder were either serving in India (70 755) or in the various colonies and dependencies of the Empire (34 904) As compared with 1912, there is an increase in the admission rate to hospital for the whole force (437 7, compared with 426 3 per 1000) for India in the ratios for admission (590 5 compared with 547·9) constantly sick (29·68 instead of 28·86), and invalids sent home (7 49 instead of 6·68) and for the United Kingdom in the ratios for admission (357 4 compared with 346 4) invaliding (9 49 instead of 9 37) and death (2 60 compared with 2 34) The constantly sick ratio for home stations the death ratio in India, and all the ratios for the colonies are lower than in 1912.

Recruiting

The number of candidates for enlistment inspected from Oct 1st, 1912, to Sept. 30th 1913 was 42,977 compared with 47 008 in 1911–12, and an average of 58 079 in the decennium 1903–12 that is a decrease of 16,102. This decrease is attributed to increased competition by the Royal Navy, to continued activity in trade and emigration and to the facilities for getting work now provided by the Government Labour Exchanges also to increased care on the part of the recruiting sergeants in selecting men for enlistment The rejection ratio on medical examination which had averaged 301 per 1000 in the decennium 1903–12, was only 202·5 in 1912–13 The chief causes of rejection were defective vision (21·97 per 1000) loss or decay of teeth (21·08) under chest measurement (18·03) and disease or disorder of the heart The rejections for defective vision are practically the same as for the two years preceding though less than the decennial average (26·93) but for the last three years a considerable relaxation in the standard has been allowed For the right eye 6 6 is required and in the left eye the vision may be only 6 60 but in certain corps, if the *left* eye can see 6 6 the recruit would be accepted even with 6 60 in the right eye for employment as a driver Loss or decay of teeth causing 21·08 per 1000 rejections compared with 22 44 in 1911–12 and 54·62 in 1903–12, does not indicate an improvement in the teeth of the rising generation but merely means that recruits are now accepted even if they do *not* have "a sufficient number of sound teeth for efficient mastication" provided that they can receive "such treatment as would enable them to be passed as fit for enlistment." It is to be hoped that the attention that is now being paid to the condition of school-children's teeth throughout the country will lead to improvement in the teeth of the young adult generally Defective chest measurement caused only 18·03 per 1000 rejections as compared with an average of 47·05 in the preceding decennium The average minimum of those accepted was 33·2 inches and the average maximum 35·6 inches as compared with 33 4 and 35·7 for the decennium. Heart disease (or disorder) caused 28·67 rejections per 1000 of which 12 89 were ascribed to valvular disease the remaining 15 78 per cent. consist of cases of "disordered action" including tachycardia due to excessive smoking and fugitive functional murmurs Less importance is now attached to abstention. From the military standpoint these cases are important They indicate that in cases of wounds in this region, when neither auscultation nor radioscopy shows anything abnormal, the conclusion that the patient is exaggerating or simulating should not be hastily adopted

---

[1] The statistics in this Report refer to conditions prevailing before the war

A SCHEME FOR A MINISTRY OF HEALTH

A MEMORANDUM presented by the National Insurance organisations of the country and printed by the Insurance Publishing Company, Limited (price 4½*d*), *contains a concrete* scheme for the establishment of a Ministry of Health and for the transference to it of functions hitherto discharged by various Government Departments The main points of the scheme are as follows —

1 A Bill to be brought in at the beginning of the autumn session which shall establish a Ministry of Health in charge of a Minister of Cabinet rank, with the specific duty of securing proper health measures and conditions throughout England and Wales

2 The Bill to transfer from the outset to the new Ministry all the functions, other than judicial and quasi judicial, of the Insurance Commissioners for England and for Wales, the excepted functions being transferred to a special body to be set up by Order in Council

3 To transfer also to it from the outset all the more directly medical functions of the Local Government Board under the Public Health Acts, and at a later stage its other functions under those Acts, but none of its functions under the Poor law until certain other changes have first been made

4 To transfer also to it from the outset the functions of the Board of Education as regards maternity and infant welfare, and later on in respect of crèches

5 To transfer to it from the outset the functions of the Privy Council in respect of Midwives, and, later on, its other medical or analogous functions

6 To transfer to it at a later stage the functions of the Registrar General, certain functions of the Home Office, and those of the Board of Control for Lunacy

The suggested Bill is to be accompanied by Exchequer grants to be disbursed by the new Ministry for promoting health schemes of local authorities The memorandum urges the Government to press on with legislation so that the scheme may come into effective practical working by the beginning of 1918 However improbable may be the immediate realisation of such a scheme and all that it entails, we welcome the clear statement of the aims of the Approved Societies as a basis for discussion

PARAFFIN AND AMBRINE IN THE TREATMENT OF WOUNDS

THE method recently brought forward by Barthe for burns and frost-bites by the use of ambrine is a rational method of treatment for wounds in general, inasmuch as it affords an absolute protection for young epithelium The special properties which its originator claimed for ambrine were a definite melting point a definite rate of cooling, tolerance of the tissues to its heat, and its retraction on cooling Professor Masnata having made extensive experiments as regards the relative physical properties of ambrine and pure paraffin having a melting point between 50° and 52° C, has come to the conclusion that the therapeutic properties of ambrine are due entirely to the paraffin[1] He found that the paraffin formed a covering round wounds which adapted itself to the most minute sinuosities, protecting them efficiently and keeping them immobile The excellent results obtained by this method, he says, must be attributed to this property of paraffin of adapting itself to the tissues without adhering to them, so that when the dressing is removed there is no lesion to the superficial granulations nor the least trace of blood The secretions find their way along the internal surface of the paraffin layer and are absorbed by the gauze at its edge The absence of any irritation or injury to the wound facilitates to a marked degree the proliferation of epithelium, rendering the use of nitrate of silver to reduce exuberant granulations unnecessary Professor Masnata made use of paraffin in a very similar manner to that advocated by Dr Barthe for ambrine The paraffin, which should have a melting point of 50° to 52° C, is liquefied in a porcelain dish and raised to a temperature of 120°–150° for sterilisation, it is then poured into a *bain marie* and cooled to 70°–80° C, and kept at this temperature during use After the wound has been cleansed with sterilised gauze and warm water it is dried, preferably by a current of hot air from an electric apparatus, and then, by means of a large soft brush which has been sterilised by immersion in the heated paraffin, a layer is gently applied all over the surface Absorbent wool and bandage complete the dressing After dressings are made every 24 hours or every two days, according to the amount of secretion, removal is easy as the layer of paraffin comes away with the wool and does not stick either to the skin or to the wound.

A NOMENCLATURE OF SMELLS

A CORRESPONDENT asks, Is there no genius prepared to give us a nomenclature of smells? and, referring to a paper on "Wound Treatment" in our columns, suggests that it ought to be possible to name a wound smell, and so to obviate the despatch of samples An approach has been made many times, but with little success, to the establishment of a system of nomenclature comparable for smells with the classification which we have been able to set up in the cases of the senses of seeing and hearing The fact is that, so far, smells have not been capable of the analysis which is possible with light and sound In both these cases we have a gamut or a law of octaves, as also with the atomic weights in chemistry, and perhaps some day a similar analysis in regard to odours will be forthcoming At present we are without a nomenclature, and everybody experiences the difficulty of describing a smell We have to be content to say that a given smell resembles another smell which is more or less familiar The fact is that the sense of smell has been the least cultivated of the senses, and it is just possible that if the subject had received the same attention as have the senses of hearing and sight the study of odours would have reached a higher scientific plane, though, it appears to us, the classification of smells must always suffer from the absence of the mathematical analysis capable in optics and acoustics As it is, in our struggle to describe a smell we are confined to using such terms as peculiar, persistent, pleasing, disagreeable, sour, bad, musty, sickly, and so forth Now these are all adjectives which give us little enlightenment We appreciate at once what is the colour of an object called red, and when we fall back on the reference to common objects, for the and the prolongation of the hot weather into November" 56 cases were found to be of the malignant tertian type In Peshawar 134 cases were of this type It is stated that larvæ of M culicifacies were found in the fire-tanks at the arsenal at Pindi and that at Lahore anopheline mosquitoes were numerous, also that numerous water channels with general water logging of the soil foster their breeding anophelines are abundant at the brickworks within half a mile of the barracks At Karachi also the admission rate (359 9 per 1000) greatly exceeded that of 1912 the battalion chiefly affected occupied lines through which runs a large *nullah* in which a great deal of water lodges in the rains" All these excessive prevalences of malaria are therefore explained but no explanation is afforded how it happened that such well known fever producing conditions were allowed to exist in the year 1913 It is stated that the work of reducing the breeding places of anophelines is tedious exacting and requires unremitting attention and supervision and in the absence of radical and prohibitively expensive operations it has to be carried out year after year" Proximity to bazaars and lack of active coöperation on the part of the civil authorities also tend to neutralise prophylactic measures in cantonments There seems to be a note almost of despair in regard to the whole matter It would appear that some vigorous action on the part of Government is required to compel the civil authorities" to put a stop to the propagation of disease amongst the British troops—that is, to prevent the latter being poisoned by the insanitary conditions prevalent in the civil areas The question of the provision of mosquito nets presents many difficulties Except in a few places nets are not provided by Government. .. In several reports it is stated that the punkah coolies were infected with malaria in one station (Fort Govingarh Amritsar) 84 per cent were so infected" Electric fans are recommended so that the cooly may be eliminated The survey of malarial stations with a view to systematic eradication of malarial conditions is required There are instances of stations where formerly malaria was both prevalent and malignant in which it is now so mild as not to call for quinine prophylaxis"

---

[1] Policlinico Surgical Section June 15th 1917

In contrast with the unsatisfactory condition of matters in regard to malaria prevention may be mentioned the absence of plague and the practical absence of cholera (5 cases 1 death) and small pox (14 cases 1 death) There were 746 cases of dengue 310 cases occurring at Ambala at three stations it was suggested that *Stegomyia calopus* may be a carrier but at Dinapur the most careful use of mosquito-nets at night did not stop the spread of the disease

OTHER STATIONS ABROAD

In Egypt, where the force numbered 5618, the admission ratio (415·5) and the ratio of constantly sick (23 85) were both considerably below the quinquennial averages of 568 1 and 36·95 per 1000. The death rate (3 74) was also less than the average (3·93) Most of the troops are stationed in Cairo There were only 6 cases of enteric fever (all in Cairo) one of whom was an orderly of the Royal Army Medical Corps who had been nursing an enteric patient. There were five cases of Mediterranean fever the cause could not be traced only tinned milk is used by the troops In 1912 there had been 39 cases of *Bilharzia hæmatobia* infection, which caused the invaliding out of the service of 19 men It was suspected that infection came from the use of the floating bath in the Nile This was discontinued shower baths being substituted In 1913 the garrison was quite free from the disease. Beri beri appeared for the first time in this command there were 17 cases all in the Welsh Regiment with 1 death The outbreak died down as soon as improvements were made in the vegetable ration In Gibraltar and Malta the health of the troops was satisfactory There were no cases of Mediterranean fever at Gibraltar and in Malta there were only three two of whom admitted drinking goats milk In South Africa the strength of the garrison was reduced from 10 488 in 1912 to 6703 in 1913 the stations of Harrismith and Tempe being no longer occupied All he ratios are higher than in 1912, and all (except the admission rate) are higher than the quinquennial average (1903-12) this is stated to be due to the excessive prevalence of venereal disease For the whole command the venereal admission ratio was 70 7 in the Cape peninsula the ratio was 195·2 per 1000 and at Wynberg 42 2 per cent of the admissions to hospital and 54 9 per cent of the average constantly sick were due to this cause The total admission ratio for South Africa was 353·9 the average constantly sick 24 69 the deaths 3 88, and the invaliding 17 45 per 1000; the corresponding ratios for 1903-12 were 355 3 21·04 3 77 and 5·97 per 1000 In West Africa, Bermuda Ceylon South China, Jamaica, Mauritius, and the Straits Settlements the health conditions have been on the whole satisfactory with less sickness than in recent years this has been particularly noticeable in Bermuda Jamaica Mauritius and the Straits Settlements In North China the admissions (649 8) invaliding (11 89) and average constantly sick (45 33) have been in excess of the quinquennial average due chiefly to malaria (103 3 admissions per 1000) and venereal disease (246 4)

The report is somewhat late in its appearance but considering the conditions that prevail at the present time the authorities are to be congratulated on having succeeded in producing it at all It is a model of clearness of arrangement and accuracy in printing and will be of permanent historic value as exhibiting the health conditions of the British Army immediately before the outbreak of the European War after the conclusion of which there may be great changes in matters military and medical as well as in the map of Europe

---

SURGEON GENERAL SIR PARDEY LUKIS's term of office as Director General of the Indian Medical Service has been further extended for one year to Dec 31st 1918 when he will have occupied this high office for nine years

A HEALTH visitor has just been appointed at Camborne (Cornwall) by the local urban council The infant mortality rate in the district is stated to be 30 per cent higher than the average rate for England and Wales

Correspondence.

"Audi alteram partem"

MALARIA CONTRACTED IN ENGLAND

To the Editor of THE LANCET

SIR,—In your issue of last week is an account of a case of malaria said to be contracted in England In reading the description of the case the evidence for deducing that the infection was contracted in England seems to be totally inadequate The patient was in Salonika, a noted centre for malarial infection, last year, and there seems to me every reason for supposing that the infection was contracted there and the attack which he has recently had is only a relapse of the old infection.—I am, Sir, yours faithfully,

H. B NEWHAM, M D Durh, M R C P Lond,
Director London School of Tropical Medicine Royal Albert Dock, E
Oct 8th 1917

THE STATUS AND FINANCIAL POSITION OF THE LONDON LOCK HOSPITALS

To the Editor of THE LANCET

SIR,—A great deal of misapprehension seems to exist in both medical and lay minds regarding the position of the London Lock Hospitals so, at the request of the board, I have been desired to write asking you to be so kind as to insert this explanatory letter in the hope that it will clear away any misconception that may exist

The Male and Female Lock Hospitals, which were founded in 1746 have been the principal centres for the treatment of venereal diseases in England since that date and on the coming into force of the Venereal Diseases Regulations 1916 the Lock Hospital immediately applied for approval under the new scheme This was granted by the Local Government Board at the close of last year and a grant-in aid is now received at both institutions towards the work being done, but the Lock Hospitals have always dealt with large numbers of cases, in addition to those treated within the London County Council area, and experience has proved during the last nine months that more than ever is the hospital called upon to deal with cases of venereal disease that do not come within the scope of the new scheme, which, it must be remembered, only applies to venereal diseases in their early and communicable stages

After allowing for the grant-in aid referred to above the hospital has to raise in voluntary contributions a sum estimated at over £9000 per annum, and the board earnestly desire that the medical and the lay public should realise the true position of the Lock Hospitals at the present time when an idea appears to exist that the hospitals are entirely supported by grants from the Local Government Board an impression which may seriously damage any efforts to obtain the necessary funds to carry on the important work at both institutions —I am Sir, yours faithfully,

J ERNEST LANE
Major R.A M C Member of the Board of Management and
Chairman of the Medical Committee
London Lock Hospital and Rescue Home, Harrow road
London W Oct 4th 1917

BREAST-FEEDING AND THE NERVOUS INFANT

To the Editor of THE LANCET

SIR,—Dr H Waller writes kindly, in your issue of Sept 22nd, on my note on nervous unrest in the newly born but disagrees He will have nothing to do with my views that in many babies digestion and appetite and the power of suction are all inhibited by excessive crying and emotional display with its accompanying vasomotor changes and the setting free of internal secretions He is clearly right when he urges that a complete physical examination of the child should be made to search for any cause for the failure to nurse but he does not appear to appreciate that in saying so he is only restating the main contention in my papers I drew up a long list of such causes to be found in the child—and in it I included Dr Waller's example of birth trauma—but added later that in many children no such cause was to such conditions and there are *consequently likely to* be fewer rejections under these headings Of the whole body of recruits finally accepted (excluding those under 18) the average age was 19 7 years height 66 2 inches minimum chest measurement 33 2 inches *maximum* chest measurement 35 6 inches range of expansion 2 6 inches and weight 127 7 lb These figures are practically the same as the average of the decade 1903-12. The standard was therefore being maintained It is stated however that many recruits enter in very poor condition and until they have been well fed for a short time and given moderate exercise they are quite unfit for their work on the square or in the gymnasium With plenty of good food and careful physical training by graduated exercises the improvement is very great being shown in a general way by the look of health and smartness of bearing and especially by the rapidity with which the pulse-rate returns to normal after exertion and by the manner in which backward recruits become alert

Invaliding

The ratio for invaliding out of the service was 7 88 per 1000 contrasting favourably with the preceding quinquennial average of 8 88 (1908-12) The most important classes of disease rendering a man unfit for service were as usual those of the nervous system (1 42 per 1000) especially epilepsy (0 62) and melancholia (0 18 per 1000) of the circulatory system (1·02) and tuberculous affections (1 31) These ratios are however, less than the quinquennial averages for the nervous and circulatory diseases (which had been 1 61 and 1 38 respectively) but slightly in excess of the tuberculous figure (1 29) for the preceding five year period Only 27 men were invalided for syphilis (0 12 per 1000) The average for 1908-12 was 0 21 and for 1892-1901 it was 1·26 per 1000 The beneficial *effects of modern methods of prevention* and treatment are obvious

Vaccination

During 1913 *there were* 4219 *children in Army* families vaccinated primarily (at home and abroad) with a percentage success of 91 3 of these 2685 received lymph from a Government establishment giving a percentage success of 97 1 There were also 1197 children revaccinated with a total percentage success of 76 6 with Government lymph this was 94 1 The recruits revaccinated with Government lymph numbered 16 875 with a percentage success of 91 4 in addition 19 were vaccinated from other sources with 84·2 per cent success The soldiers revaccinated numbered 14 982 of whom 3820 with Government lymph gave a percentage success of 86 2 while for 11,162 revaccinated from other sources the corresponding ratio was 51 7 per cent It is obvious from these figures that revaccination of the young adult is absolutely necessary to afford protection It also appears to be the case that infant vaccination is often inefficient otherwise revaccination of children (with Government lymph) would not give a successful percentage of 94 1

HEALTH OF THE TROOPS IN THE UNITED KINGDOM

The following short table shows the improvement that has taken place of late years in the health of the Army at home The figures are ratios per 1000 —

	Admissions.	Constantly sick	Deaths	Invalids
1889–98	712·5	41 14	4 32	16 98
1908–12	368·9	21 13	2·53	10 64
1912	346 4	19 50	2 34	9 37
1913	357 4	19 16	2·60	9 49

The slight cases of sickness treated in barracks averaged 7 10 per 1000 constantly sick in addition this combined with the hospital ratio gives 26 26 being 0·48 per 1000 less than in the previous year It seems probable that there will be little if any further reduction in the amount of sickness *or invaliding or in the death rate of the troops* serving at home

The admissions were highest in the London district (480 5 per 1000) and lowest in the Scottish Command (208 1) the average number constantly sick was also highest in London (28 89) and was lowest in the Western Command (10 62) Comparing the different arms of the Service the Household Cavalry have the highest admission rate (695 7) and the Foot Guards the greatest number constantly sick (27 61) For the infantry of the Line the corresponding ratios were 381 9 and 20·93 per 1000 The diseases causing most mortality at home were pneumonia (with 26 deaths) pulmonary tuberculosis *(25 deaths)* and appendicitis (13 deaths) The greatest amount of inefficiency from sickness was caused by venereal disease (4·57 per 1000 forming 23 9 per cent. of the *total)* but both actually and relatively there is an improvement on the preceding year and on the quinquennium the chief causes for invaliding out of the Service were tubercular disease (1 46 per 1000 of which 1 29 was pulmonary), nervous diseases (1 01) and valvular heart disease (0·93 per 1000)

INDIA

The strength of troops serving in India during 1913 averaged 70 755 warrant officers non-commissioned officers and men Their health continued to be satisfactory as is shown in the following abstract of ratios per 1000 of strength —

	Admissions	Constantly sick.	Deaths	Invalids
1889-98	1464 7	89·61	16 43	27·95
1908–12	638 5	35·03	6 02	9·19
1912	547·9	28 86	4·62	6·68
1913	580 5	29 68	3 26	7 49

There is a slight increase in the admission ratio over the preceding year (as there had been in 1912) and the constant inefficiency from sickness and the invaliding are practically the same as before but the death ratio shows a marked improvement, as is the case in all particulars compared with the quinquennial average *the improvement is* still more noticeable on comparison with the statistics of the decennium before the South African War The admissions are about two-fifths the constantly sick *one-third the invalidings* little more than one quarter and the deaths less than one-quarter of the average 1889-1893 With regard to the increase in the admission ratio compared with the three preceding years it is stated that there has been a prevalence of malaria sandfly fever and dengue in the Northern Army and that a large number of cases of ear disease have been admitted to hospital that would formerly have been treated as out-patients in barracks

There were three large stations that showed very high admission ratios—Lahore (1252 2 per 1000) Rawal *Pindi* (1127·9) and Peshawar (1007) The average numbers constantly sick were also high in these stations the figures being 44 68 44 00 and 38·65 per 1000 respectively The death rate was *high in Rawal* Pindi (5 36) moderate in Lahore (3 49) and extraordinarily low in Peshawar (1 death = 0 59 per 1000) The highest death rates at large stations with over 1000 troops were experienced at Fort William (8 39) Rangoon (7 81) and *Karachi (6 24)*

The disease that caused the greatest number of admissions has been as always malarial fever (125 5 per 1000) This is less than the quinquennial ratio (1908–12) of 149 5 but higher than the figure for 1912, which was 82 4 per 1000 Sandfly fever (28·9) was rather less prevalent than in 1912, when the ratio was 30 5 The quinquennial average was 11 4 Pyrexia of uncertain origin caused only 15 6 admissions per 1000 a great reduction on the quinquennial average of 43·9 due presumably to more accurate diagnosis It is stated (p. 44) that the term is used to include practically all pyrexial states that cannot be *clearly designated in any other way* the duration of the fevers so classified varying from days to months Under this head are probably embraced undiagnosed enteric, paratyphoid sandfly and malarial fevers influenza, gastro-intestinal disturbances &c For *malaria, sandfly* fever and pyrexia of uncertain origin, the total admission ratio was 170·0 per 1000 in 1913 and 204·8 in the preceding quinquennium Venereal diseases caused 52 5 admissions per 1000 compared with 61·0 in the preceding quinquennium: the average number constantly sick that is the inefficiency due to these affections was 6·90 per 1000 compared with 7 85 in the quinquennium there is a continuous improvement, and when the statistics of former years are referred to the condition of things is seen to be altogether different: the average venereal admission rate in the decennium 1889–1898, was 383·8 per 1000 and the *average number constantly sick was 32·81 per 1000* The most fatal diseases were enteric and paratyphoid fevers (0 26 deaths per 1000) inflammation and suppuration of the liver (0 24) and pneumonia (0 23 *per 1000)*

Although enteric fever is of nothing like the same importance nowadays as was formerly the case in India, when (as in 1898) it accounted for 50 per cent. of the deaths occurring among British troops (2375 cases and 654 deaths, the ratios being 36 3 and 10·0 per 1000 respectively) it still holds the highest place in the mortality table There were 85 cases and 16 deaths in addition, there were 79 cases of paratyphoid A with 2 deaths For both together the admissions numbered 164 and the deaths 18 the combined ratios being 2 3 and 0·26 per 1000 The Report states that *there were fewer cases of* enteric fever and a lower *mortality from that disease in 1913 than in any previous year* This diminution is more striking than at first sight appears for with modern methods of diagnosis it is probable that a smaller proportion of cases of both enteric fever and paratyphoid fever escape detection " The improvement was still continuing In the previous year (1912) there had been 118 (or including paratyphoid A and B 182) cases and 28 deaths giving ratios per 1000 of 1 7 (or including paratyphoid 2 7) admissions and 0 40 deaths

Of the 85 cases of enteric fever in the whole army in India 67 were admitted from three out of the ten divisions that compose the European Army in that country—viz: *27 from Rawal Pindi 18 from* Poona and 12 from Secunderabad From Lucknow there were admitted 35 cases of paratyphoid A, but only 6 of enteric; and from *Poona came 13 cases of paratyphoid* A In the Rawal Pindi division 13 out of the 27 cases occurred in Rawal Pindi itself There were 4 cases in September and the remainder were spread over the rest of the year It is stated that it was found impossible to trace the source of origin of any of the 13 cases no carrier was discovered Eight cases occurred in the 21st Lancers recently arrived from Egypt, where they had been seriously affected with enteric in the preceding year In the same division 9 cases occurred *at Sialkot* no cause could be traced Of the 18 cases in the Poona division 11 occurred at Poona itself There were 79 admissions for paratyphoid *fever with only two deaths There were no* cases in Rawal Pindi The principal prevalence was in Lucknow Fyzabad and Kamptee all cases were due to *B paratyphosus A* this organism being detected either in the blood fæces or urine All of these 79 cases (except one) had been inoculated against enteric *fever* Trials were subsequently made with an antiparatyphoid vaccine prepared at the Royal Army Medical College It is stated that evidence is accumulating that the indigenous population *suffer from* paratyphoid fever to a certain extent and that it is probably more or less endemic in the country The need for bacteriological examination of all servants and followers is now getting *to be recognised* Anti enteric inoculation progresses satisfactorily over 93 per cent of the European troops having been so treated and in some units every officer and man has been inoculated All native cooks mess servants and others engaged in handling food are now inoculated as a matter of routine. The admission and death ratios per 1000 for enteric fever among the inoculated soldiers are 0·9 and 0 12 of inoculated strength respectively Among the non inoculated soldiers these *ratios are 5 3* and 1 76 of non inoculated strength Combining enteric and paratyphoid fevers the inoculated ratios are 2 10 and 0·15 and the non inoculated ratios 5 50 and 1 76 respectively *Re-inoculation* is recommended after two years The important statement is made that some infantry battalions have not had a case of enteric for over two years and it has been ascertained that in these units Indian cooks are not employed and inoculation has been adopted by all ranks almost universally " The conclusion is arrived at on a survey of all the circumstances that the progressive decline in the prevalence of the disease is due to the high proportion of men protected by anti-enteric *inoculation* the detection of carriers in barracks the elimination of convalescents by sending them to special enteric depôts in the hills the practice of night soil incineration and *consistent effort in improving* the sanitary condition in barracks and their surroundings There can be no gainsaying such a conclusion it is comprehensive and fairly obvious for the present apparently there can be no relaxation of vigilance either in general sanitary measures or in the special prophylactic *methods employed*

Malaria continues to be the dominating cause of inefficiency in European troops in India." The ratio of admissions per 1000 was highest in the Rawal *Pindi (223 1) and Peshawar* (274·6) divisions in Pindi itself the admissions were 564 7 per 1000 the increased incidence is attributed to the presence in and about the cantonment of a heavily *infected indigenous community* the intermittency of the rains and the prolongation of the hot weather into November " 56 cases were found to be of the malignant tertian type. In Peshawar 134 cases were of this type It is stated that larvæ of *M culicifacies* were found in the fire-tanks at the arsenal at Pindi and that at Lahore anopheline mosquitoes were numerous, also that numerous water channels with general water logging of the soil, foster their breeding anophelines are abundant at the brickworks within half a mile of the barracks At Karachi also the admission rate (350·9 per 1000) greatly exceeded that of 1912 the battalion chiefly affected occupied lines through which runs a large *nullah*, in which a great deal of water lodges in the rains " All these excessive prevalences of malaria are therefore explained but no explanation is afforded how it happened that such well known fever producing conditions were allowed to exist in the year 1913 It is stated that the work of reducing the breeding places of anophelines is tedious exacting and requires unremitting attention and supervision and in the absence of radical and prohibitively expensive operations it has to be carried out year after year Proximity to bazaars and lack of active cooperation on the part of the civil authorities also tend to neutralise prophylactic measures in cantonments. There seems to be a note almost of despair in regard to the whole matter It would appear that some vigorous action on the part of Government is required to compel "the civil authorities" to put a stop to the propagation of disease amongst the British troops—that is, to prevent the latter being poisoned by the insanitary conditions prevalent in the civil areas. The question of the provision of mosquito nets presents many difficulties Except in a few places nets are not provided by Government. .... In several reports it is stated that the punkah coolies were infected with malaria in one station (Fort Govingarh Amritsar) 8[illegible] per cent were so infected " Electric fans are recommended, so that the cooly may be eliminated The survey of malarial stations, with a view to systematic eradication of malarial conditions is required There are instances of stations where formerly malaria was both prevalent and malignant in which it is now so mild as not to call for quinine prophylaxis "

In contrast with the unsatisfactory condition of matters in regard to malaria prevention may be mentioned the absence of plague and the practical absence of cholera (5 cases 1 death) and small pox (1[illegible] cases 1 death) There were 7 8 cases of dengue 310 cases occurring at Ambala at three stations it was suggested that *Stegomyia calopus* may be a carrier but at Dinapur the most careful use of mosquito-nets at night did not stop the spread of the disease

OTHER STATIONS ABROAD

In Egypt, where the force numbered 5818, the admission ratio (415·5) and the ratio of constantly sick (23·86) were both considerably below the quinquennial averages of 5[illegible]6 1 and 36·96 per 1000 The death rate (3 74) was also less than the average (3·93) Most of the troops are stationed in Cairo There were only 6 cases of enteric fever (all in Cairo) one of whom was an orderly of the Royal Army Medical Corps who had been nursing an enteric patient. There were five cases of Mediterranean fever the cause could not be traced only tinned milk is used by the troops In 1912 there had been 39 cases of *Bilharzia hæmatobia* infection, which caused the invaliding out of the service of 19 men. It was suspected that infection came from the use of the floating bath in the Nile This was discontinued, shower-baths being substituted. In 1913 the garrison was quite free from the disease. Beri beri appeared for the first time in this command there were 17 cases all in the Welsh Regiment with 1 death The outbreak died down as soon as improvements were made in the vegetable ration. In Gibraltar and Malta the health of the troops was satisfactory There were no cases of Mediterranean fever at Gibraltar and in Malta there were only three two of whom admitted drinking goats milk In South Africa the strength of the garrison was reduced from 10[illegible]73 in 1912 to 6703 in 1913 the stations of Harrismith and Tempe being no longer occupied All the ratios are higher than in 1912, and all (except the admission rate) are higher than the quinquennial average (1908-12) this is stated to be due to the excessive prevalence of venereal disease For the whole command the venereal admission ratio was 70 7 In the Cape peninsula the ratio was 158·2 per 1000 and at Wynberg 42·2 per cent. of the admissions to hospital and 5[illegible]9 per cent of the average constantly sick were due to this cause. The total admission ratio for South Africa was 353·9 the average constantly sick 24·89 the deaths 3 23, and the invaliding 17[illegible]5 per 1000 the corresponding ratios for 1908-12 were 355 3 21·04 3·77 and 5[illegible] per 1000 In West Africa, Bermuda Ceylon South China, Jamaica, Mauritius, and the Straits Settlements the health conditions have been, on the whole, satisfactory with less sickness than in recent years this has been particularly noticeable in Bermuda, Jamaica Mauritius and the Straits Settlements In North China the admissions (6[illegible]9·8) invaliding (11·8[illegible]) and average constantly sick ([illegible]5·33) have been in excess of the quinquennial average due chiefly to malaria (103 3 admissions per 1000) and venereal disease (2[illegible])

The report is somewhat late in its appearance but considering the conditions that prevail at the present time the authorities are to be congratulated on having succeeded in producing it at all It is a model of clearness of arrangement and accuracy in printing and will be of permanent historic value as exhibiting the health conditions of the British Army immediately before the outbreak of the European War after the conclusion of which there may be great changes in matters military and medical as well as in the map of Europe

---

Surgeon General Sir Pardey Lukis s term of office as Director General of the Indian Medical Service has been further extended for one year to Dec 31st, 1918 when he will have occupied this high office for nine years

A HEALTH visitor has just been appointed at Camborne (Cornwall) by the local urban council The infant mortality rate in the district is stated to be 30 per cent higher than the average rate for England and Wales

MALARIA CONTRACTED IN ENGLAND

To the Editor of THE LANCET

SIR —In your issue of last week is an account of a case of malaria said to be contracted in England In reading the description of the case the evidence for deducing that the infection was contracted in England seems to be totally inadequate The patient was in Salonika a noted centre for malarial infection last year, and there seems to me every reason for supposing that the infection was contracted there, and the attack which he has recently had is only a relapse of the old infection.—I am, Sir, yours faithfully,

H B NEWHAM, M D Durh , M R C P Lond

Director London School of Tropical Medicine Royal Albert Dock, E

THE STATUS AND FINANCIAL POSITION OF THE LONDON LOCK HOSPITALS

To the Editor of THE LANCET

SIR,—A great deal of misapprehension seems to exist in both medical and lay minds regarding the position of the London Lock Hospitals, so, at the request of the board, I have been desired to write asking you to be so kind as to insert this explanatory letter in the hope that it will clear away any misconception that may exist

The Male and Female Lock Hospitals, which were founded in 1746 have been the principal centres for the treatment of venereal diseases in England since that date, and on the coming into force of the Venereal Diseases Regulations, 1916 the Lock Hospital immediately applied for approval under the new scheme This was granted by the Local Government Board at the close of last year and a grant-in aid is now received at both institutions towards the work being done , but the Lock Hospitals have always dealt with large numbers of cases in addition to those treated within the London County Council area, and experience has proved during the last nine months that more than ever is the hospital called upon to deal with cases of venereal disease that do not come within the scope of the new scheme, which, it must be remembered, only applies to venereal diseases in their early and communicable stages

After allowing for the grant-in aid referred to above, the hospital has to raise in voluntary contributions a sum estimated at over £9000 per annum, and the board earnestly desire that the medical and the lay public should realise the true position of the Lock Hospitals at the present time when an idea appears to exist that the hospitals are entirely supported by grants from the Local Government Board an impression which may seriously damage any efforts to obtain the necessary funds to carry on the important work at both institutions —I am Sir yours faithfully

BREAST-FEEDING AND THE NERVOUS INFANT

To the Editor of THE LANCET

SIR,—Dr H Waller writes kindly, in your issue of Sept 22nd on my note on nervous unrest in the newly born, but disagrees He will have nothing to do with my views that in many babies digestion and appetite and the power of suction are all inhibited by excessive crying and emotional display with its accompanying vasomotor changes and the setting free of internal secretions He is clearly right when he urges that a complete physical examination of the child should be made to search for any cause for the failure to nurse but he does not appear to appreciate that in saying so he is only restating the main contention in my papers I drew up a long list of such causes to be found in the child—and in it I included Dr Waller's example of birth trauma—but added later that in many children no such cause was to be found, and that the difficulty was then to be accounted for by the unstable nervous system of the child Dr Waller does not believe it, yet I feel sure that when he expounds the physiology of digestion to workers in infant welfare, he does not omit reference to the teaching of Pawlow on the dependence of gastric secretion upon the emotions or substitute for it entirely his own views upon the ill effects of giving the mother an enema or a dose of salts

When a baby after birth, has dyspepsia, cries ceaselessly and passionately, mothers and nurses are quick to blame some article of diet or some medicine the mother has been given To them it admits of no doubt that the milk disagrees with the child because it contains something harmful I do not believe that there is often truth in this contention. The same milk can be used for another child without ill results The disturbance is in the child It was the hope of upsetting a little the belief in these traditional views, to which Dr Waller calls my attention, that made me write as I did With him at least I have failed. He even adds to my confusion by detailing these observations of his own upon the toxic properties of milk derived from mothers who have had an enema or who have carious teeth

I am, Sir, yours faithfully

Devonshire-place, W Oct 2nd 1917 H CHARLES CAMERON

THE DIAGNOSIS OF HORSESHOE KIDNEY

To the Editor of THE LANCET

SIR,—I am induced by Dr David Newman's article entitled " Horseshoe Kidney Diagnosed Prior to Operation," which appeared in THE LANCET of August 18th, to send you this brief note Evidently it was not known to the author that in December, 1915, I determined, *exclusively* by radiological investigation, the diagnosis of horseshoe kidney in a case where the condition was confirmed by the operation At the same time I described the complex of radiological symptoms of this abnormality, which were unknown up to that moment, and fixed the typical image of it (*vide* the report of the Dutch Society for Electrology and Roentgenology of May 21st, 1916, in the *Nederlandsch Tijdschrift voor Geneeskunde*, 1916, ii , p 1250)

Dr Newman could not be aware of my case, for on account of the war the international publication of my paper, which will appear in the next number of the *Journal de Radiologie*, was retarded I am, Sir, yours faithfully,

Amsterdam, Sept. 28th 1917 N VOORHOEVE

THE EFFECT OF PITUITRIN ON BLOOD PRESSURE

To the Editor of THE LANCET

SIR,—Dr Edith M N Green's article on blood pressure and surface temperature in 110 cases of shell shock in your issue of Sept 22nd has a bearing on other conditions in which arterial pressure is depressed, and the charts and other records tend to confirm the value of pituitary extract in some of these conditions

Dr Green's paper would be of enhanced value if she would kindly inform your readers (1) Whether ' blood pressure " is intended to signify systolic pressure (2) whether the diastolic pressure was taken in any of the cases, (3) whose make of pituitary remedy was used, so as to give a clearer signification to " pituitary fluid " and extract , and (4) whether the whole gland or the posterior or anterior lobes alone, were made use of.

I am, Sir, yours faithfully,

Devonshire-place W Oct 1st 1917 R HINGSTON FOX.

A STATE-AIDED MIDWIFERY SERVICE

To the Editor of THE LANCET

SIR,—In referring to your article in THE LANCET of Sept 29th on the memorandum for State aided midwifery put forward by this association, may I point out that there has apparently been some little confusion between the proposals of this association and the scheme so ably thought out by Dr E W Hope, of Liverpool ?

Dr Hope, in his admirable address at the meeting of this association in July spoke of the success of the efforts of the State to improve the position of the midwife, but that it was necessary to go much further, and it is with the hope of covering the whole field (with the welfare of the mother and child as the first objective) that the memorandum issued by this association has been formulated It is estimated that its provisions will cost the country a million a year (not £100,000), but this sum would, undoubtedly, be repaid over and over again if they secure to every mother the skilled attention necessary for the well being of herself and her child I am, Sir, yours faithfully,

EMILY F FORD,

Secretary Association for Promoting the Training and Supply of Midwives

Dacre House Westminster, S W , Oct 3rd 1917

*** Having read again the proposals put forward by the association for a State aided midwifery service, we see how we were led to mistake our previous correspondent's accurate notes We are glad to publish Miss Ford's correction — ED L

THE TREATMENT OF IMPETIGO AT THE FRONT

To the Editor of THE LANCET

SIR —Impetigo and its treatment is a considerable source of difficulty to the medical officer in charge of a unit on active service Especially does this apply to artillery units, which are sometimes many weeks in the "line " Under these circumstances it is very difficult for the men to obtain baths and clean underclothing In consequence a fair number of men get impetigo I tried various remedies, such as the unguentum hydrargyri ammon , ung acid. borici, covering the affected parts with plain lint afterwards The results were disappointing Then tinct iodi painted on the affected parts and afterwards covering the area, as in the former treatment, with plain lint This certainly gave considerably better results

The best results, however, have been obtained by using methylated spirit The procedure adopted was first of all to remove the crusts with boric fomentations, and then swabbing the area affected by impetigo with methylated spirit Within a few days the relief was very marked All the affected parts were covered with plain lint, secured in position either with a bandage or strapping

I thought the above treatment would interest your readers, especially those who are on active service on the Western Front —I am, Sir, yours faithfully,

FRANK HARVEY,

In the Field, Sept 3rd 1917 Captain R.A M C (T)

COLOUR WARDS IN HOSPITALS

To the Editor of THE LANCET

SIR,—With regard to the end of the annotation in your issue of last week on the use of colour in hospital wards I shall be pleased to supervise colour schemes for any hospital in London or other town I do not take any money for such supervision I am, Sir, yours faithfully,

H KEMP PROSSOR.

11 South Eaton place S W Oct. 8th 1917

Corrigendum —In the address at the foot of Mr Edred M Corner s letter in our last week s issue, calling attention to a War Memorial for Old Epsomians, a figure has broken off It should read *37* Harley street

---

THE COLLEGE OF AMBULANCE —The Bishop of London, who presided at the opening of the fourth year of the work of the college on Monday, Oct 8th, announced the offer of what he termed a 'parsons' ambulance" for the front line service Incidentally Dr Ingram mentioned the experience of a rescuing party of 50, including his own chaplain, who were out for 4½ hours in a heavy barrage and succeeded in bringing in, without one of the rescuing party being hit 12 men who had lain out for three days and three nights On the motion of Sir Malcolm Morris seconded by Professor J G Adami, a resolution was passed to the effect that the work done justified the existence of the college, and the Bishop of London was made the first honorary fellow Colonel James Cantlie said that the number of students who had passed through the college, which was founded in 1914 as a teaching institution, exceeded 14 000 All communications should be made to Mrs Colin Macdonald, the secretary 3, Vere street, London, W 1

The War.

THE CASUALTY LIST

THE following names of medical officers appear among the casualties announced since our last issue —

Killed

Lieut. Col J J Nicholas, Australian A.M C, qualified at Melbourne in 1911.

Capt H. D N Mackenzie, R.A.M C, attached Royal Field Artillery, was educated at Edinburgh University and at Middlesex Hospital, London, and qualified in 1895 After holding appointments at the North West London Hospital, the Birmingham General Hospital, and at the Throat Hospital, Golden square, London, he travelled abroad and served as a civil surgeon in the South African War Later he became a special plague medical officer in India and Egypt and prior to the outbreak of war was in practice at Corowa, New South Wales. He joined the R A.M C towards the end of 1915 and did duty at the Dardanelles in Egypt and on the Western front

Capt J P Pegum, R.A.M C, attached Shropshire Light Infantry qualified in 1916, and thereupon joined up

Capt. T J Golding, R.A.M C, qualified in Ireland in 1906, and was in practice in Cork before joining the R.A.M.C

Died of Wounds

Capt H. D Field, R.A.M.C, was a student at St Thomas's Hospital London, and qualified at the latter end of 1914 After holding an appointment at the Royal Victoria Hospital Bournemouth he joined the R A.M C in April 1915

Died

Capt J W Pettinger, R.A.M.C, was educated at Cambridge and at St George's Hospital, London, and qualified in 1899 He was in practice at Kingsbridge, South Devon, before joining up and died of pneumonia at the Military Hospital, Aldershot.

Wounded

Lieut F H. Fuller, R.A.M C, attd. Royal Garrison Artillery
Capt. M. B Lawrie, M.C, South African M.C
Capt. G W Armstrong R.A.M C attd North Staffs Regt.
Lieut. J Rickards, M.C, R.A.M C, attached Royal Scots.
Surgeon A. G Williams, R N
Major G Craig, New Zealand M C
Capt G Redpath New Zealand M C

Capt W A. Rees R A M C

CASUALTIES AMONG THE SONS OF MEDICAL MEN

The following additional casualties among the sons of medical men are reported —

Commander R H Graves Burton R D, R N R died suddenly youngest son of Surgeon Major R Graves Burton of Ealing London

Major F M Armstrong Royal Field Artillery killed in action son of the late Dr J F Armstrong of South Shields

Flight Sub-Lieut E C Hillaby R N killed in action, second son of Dr A Hillaby of Pontefract

Sergeant Major F P Hawkley Australian Imperial Force died of wounds only son of Dr F Hewkley of New Cross

Second Lieut L A Joscelyne, M C Somerset Light Infantry killed in action only son of Dr A E Joscelyne of Taunton

Major W G Harington D S O Indian Army died of wounds elder son of Lieut Col H N A Harington I M S (retired)

Lieut J T Willis Royal Flying Corps killed in action only son of Dr J G Willis of Ilkeston Derbyshire

Capt J W Pettinger R A M C died of pneumonia son of the late Dr G W Pettinger of Manchester

Capt J I Chetham Strode Border Regiment killed in action son of Dr J Chetham Strode of Wimpole street and Acton hill London

OBITUARY OF THE WAR

JAMES HENRY BAMPTON M.B, CH B, B SC BIRM

CAPTAIN ROYAL ARMY MEDICAL CORPS

Captain J H Bampton, who died of wounds on August 25th, at the age of 29 years, was elder son of Henry Bampton L.D S of Gravelly Hill, Birmingham He was educated at King Edward's Grammar School, Aston, and the University of Birmingham, graduating in science in 1908 and in medicine three years later After filling resident posts at the General Hospital, Birmingham, he was awarded in 1913 the Walter Myers travelling scholarship, and spent 12 months in research work in bacteriology at Hamburg and Berne, publishing a thesis in the *Centralblatt für Bakteriologie* He then obtained a post as assistant medical officer under the Birmingham Education Committee, which he resigned in February, 1915 on obtaining a commission in the Royal Army Medical Corps He was engaged first on embarkation duty, and later on an ambulance-train and on hospital ships At the beginning of 1917 he went to France, where he was attached to the Royal Flying Corps and subsequently to the Royal Field Artillery, when in the fulfilment of duty he met his death

BERNARD WOODHOUSE, M B, B S LOND,

CAPTAIN ROYAL ARMY MEDICAL CORPS

Captain B Woodhouse, who was killed on active service on Sept. 5th was younger son of the late Lister Woodhouse, of Wimbledon He was educated at Birkenhead School and Cheltenham College, afterwards taking his medical course at University College Hospital. Qualifying in 1913 he held resident appointments at Westminster and University College Hospitals before obtaining his commission in August, 1914 He had just completed three years service at the front when he received shrapnel wounds which proved fatal on the next day At the time of his death he was attached to a Welsh regiment One of Captain Woodhouse's teachers writes of him as a man who gave great promise of good things His commanding officer wrote A man of great kindness and thoughtfulness for others especially for the wounded and sick We all loved him

FREDERICK HARDIE M B CH B EDIN,

CAPTAIN ROYAL ARMY MEDICAL CORPS

Captain F Hardie who died of wounds on Sept 20th at the age of 41 years was a student of Edinburgh University graduating there in medicine in 1900 After some time a Bentham he settled in private practice at Southampton - but in October 1914 obtained a commission in the Royal Army Medical Corps attached to a Wessex ambulance Nine months later he was sent to France with a field ambulance and after many near escapes he was killed by a shell from an aeroplane at his ambulance headquarters be found, and that the difficulty was then to be accounted for by the unstable nervous system of the child Dr Waller does not believe it, yet I feel sure that when he expounds the physiology of digestion to workers in infant welfare, he does not omit reference to the teaching of Pawlow on the dependence of gastric secretion upon the emotions or substitute for it entirely his own views upon the ill effects of giving the mother an enema or a dose of salts

When a baby after birth, has dyspepsia, cries ceaselessly and passionately, mothers and nurses are quick to blame some article of diet or some medicine the mother has been given To them it admits of no doubt that the milk disagrees with the child because it contains something harmful I do not believe that there is often truth in this contention. The same milk can be used for another child without ill results The disturbance is in the child. It was the hope of upsetting a little the belief in these traditional views, to which Dr Waller calls my attention, that made me write as I did With him at least I have failed He even adds to my confusion by detailing these observations of his own upon the toxic properties of milk derived from mothers who have had an enema or who have carious teeth

I am, Sir, yours faithfully

Devonshire place, W Oct 2nd, 1917 H Charles Cameron

THE DIAGNOSIS OF HORSESHOE KIDNEY

To the Editor of The Lancet

Sir,—I am induced by Dr David Newman's article entitled "Horseshoe Kidney Diagnosed Prior to Operation," which appeared in The Lancet of August 18th, to send you this brief note Evidently it was not known to the author that in December, 1915, I determined, *exclusively* by radiological investigation, the diagnosis of horseshoe kidney in a case where the condition was confirmed by the operation At the same time I described the complex of radiological symptoms of this abnormality, which were unknown up to that moment and fixed the typical image of it (*vide* the report of the Dutch Society for Electrology and Roentgenology of May 21st, 1916, in the *Nederlandsch Tijdschrift voor Geneeskunde*, 1916, ii, p 1250)

Dr Newman could not be aware of my case, for on account of the war the international publication of my paper, which will appear in the next number of the *Journal de Radiologie*, was retarded I am, Sir, yours faithfully,

Amsterdam, Sept 28th 1917 N Voorhoeve

THE EFFECT OF PITUITRIN ON BLOOD PRESSURE

To the Editor of The Lancet

Sir,—Dr Edith M N Green's article on blood pressure and surface temperature in 110 cases of shell shock in your issue of Sept 22nd has a bearing on other conditions in which arterial pressure is depressed, and the charts and other records tend to confirm the value of pituitary extract in some of these conditions

Dr Green's paper would be of enhanced value if she would kindly inform your readers (1) Whether blood pressure" is intended to signify systolic pressure (2) whether the diastolic pressure was taken in any of the cases, (3) whose make of pituitary remedy was used, so as to give a clearer signification to "pituitary fluid" and extract, and (4) whether the whole gland or the posterior or anterior lobes alone, were made use of

I am, Sir, yours faithfully,

Devonshire-place W Oct 1st 1917 R Hingston Fox

A STATE-AIDED MIDWIFERY SERVICE

To the Editor of The Lancet

Sir,—In referring to your article in The Lancet of Sept 29th on the memorandum for State aided midwifery put forward by this association, *may I point out that there* has apparently been some little confusion between the proposals of this association and the scheme so ably thought out by Dr E W Hope, of Liverpool?

Dr Hope, in his admirable address at the meeting of this association in July spoke of the success of the efforts of the State to improve the position of the midwife, but that it was necessary to go much further, and it is with the hope of covering the whole field (with the welfare of the mother and child as the first objective) that the memorandum issued by this association has been formulated It is estimated that *its provisions will cost* the country a million a year (not £100,000) but this sum would, undoubtedly, be repaid over and *over again if they secure* to every mother the skilled attention necessary for the well being of herself and her child I am, Sir, yours faithfully,

Emily F Ford,

Secretary Association for Promoting the Training and Supply of Midwives

Dacre House Westminster, S W Oct 3rd 1917

*** Having read again the proposals put forward by the association for a State aided midwifery service, we see how we were led to mistake our previous correspondent's accurate notes *We are glad to publish Miss Ford's correction*—Ed L

THE TREATMENT OF IMPETIGO AT THE FRONT

To the Editor of The Lancet

Sir,—Impetigo and its treatment is a considerable source of difficulty to the medical officer in charge of a unit on active service Especially does this apply to artillery units, which are sometimes many weeks in the "line." Under these circumstances it is very difficult for the men to obtain baths and clean underclothing In consequence a fair number of men get impetigo I tried various remedies, such as the unguentum hydrargyri ammon, ung acid borici, covering the affected parts with plain lint afterwards The results were disappointing Then tinct. iodi painted on the affected parts and afterwards covering the area, as in the former treatment, with plain lint This certainly gave considerably better results

The best results, however, have been obtained by using methylated spirit The procedure adopted was first of all to remove the crusts with boric fomentations, and then swabbing the area affected by impetigo with methylated spirit Within a few days the relief was very marked All the affected parts were covered with plain lint, secured in position either with a bandage or strapping

I thought the above treatment would interest your readers, especially those who are on active service on the Western Front—I am, Sir, yours faithfully,

Frank Harvey,
Captain R.A M C (T)

In the Field Sept 3rd 1917

COLOUR WARDS IN HOSPITALS

To the Editor of The Lancet

Sir,—With regard to the end of the annotation in your issue of last week on the use of colour in hospital wards I shall be pleased to supervise colour schemes for any hospital in London or other town I do not take any money for such supervision I am Sir, yours faithfully,

H Kemp Prosser

11 South Eaton place S W, Oct. 8th 1917

Corrigendum—In the address at the foot of Mr Edred M Corner's letter in our last week's issue, calling attention to a War Memorial for Old Epsomians, a figure has broken off It should read *37*, Harley-street

The College of Ambulance—The Bishop of London, who presided at the opening of the fourth year of the work of the college on Monday, Oct 8th, announced the offer of what he termed a 'parsons' ambulance" for the front line service Incidentally Dr Ingram mentioned the experience of a rescuing party of 50, including his own chaplain, who were out for 4½ hours in a heavy barrage and succeeded in bringing in, without one of the rescuing party being hit, 12 men who had lain out for three days and three nights On the motion of Sir Malcolm Morris seconded by Professor J G Adami, a resolution was passed to the effect that the work done justified the existence of the college, and the Bishop of London was made the first honorary fellow Colonel James Cantlie said that the number of students who had passed through the college, which was founded in 1914 as a teaching institution, exceeded 14 000 All communications should be made to Mrs Colin Macdonald, the secretary, 3, Vere street, London, W 1

HOSPITAL TREATMENT OF THE INVALIDED SAILOR OR SOLDIER

Representatives of the honorary medical staffs of the voluntary hospitals of the County Palatine of Chester (and of some of those situate in the counties adjacent) and officers of the local Medical and Panel Committee met at Crewe on Sept 29th to confer on the position of the honorary medical staffs of voluntary hospitals in undertaking the care of invalided seamen and soldiers under arrangement with the Ministry of Pensions Dr J H Marsh of Macclesfield General Infirmary, chairman of the local Medical and Panel Committee, occupied the chair The following resolutions were passed unanimously, and it was decided to submit them to the consideration of the various hospitals concerned, to the Ministry of Pensions, and to the county Pensions Committees —

That the services of the medical profession should not be given gratuitously to patients who are maintained by public funds

That from all payments received by the governing body of a voluntary medical institution from the State or local authority a proportion to be agreed upon between the governing body and the honorary medical staff should be placed to a special fund which shall belong to the honorary medical staff

A scale of charges was also resolved upon, the chief items being as follows —

	£	s	d.
For major operation including anæsthetist s and assistant s fees ..	7	7	0
For minor operation requiring general anæsthesia, including an anæsthetist s fee ..	2	11	6
The anæsthetist s fee (included in the above fees) where the assistant is not a salaried resident medical officer	1	1	0
For minor operation with local anæsthetic ..	1	1	0
For attendance on in patients (after operation or otherwise) for each week	1	1	0

(For less than a week in proportion)

"OUR DAY"—Red Cross work is now said to be costing the country something over £6 a minute, and next Thursday (Oct 18th) an effort will be made to collect a sum of money sufficient to enable the Red Cross to carry on its beneficent work on behalf of the sick and wounded Flags and emblems will be sold as usual on "Our Day" throughout the country several metropolitan mayors have opened supplementary subscription lists and social gatherings of various kinds will further the appeal. Helpers are needed, particularly for the South African section Offers of assistance, gifts, and suggestions will be welcomed by Miss C May Beeman, the organising secretary, 10 West Bolton Gardens, S W 5 —The Viceroy of India has fixed Dec 12th for "Our Day' in India —Americans in England are making a combined present to the British Red Cross Society for "Our Day and contributions for this purpose should be sent to Mr Clarence C Stetson care of The National City Bank of New York 34, Bishopsgate London, E C 2

FIRST AMERICAN RED CROSS HOSPITAL IN EUROPE.—On Oct 4th Mr Page the United States Ambassador opened the first American Red Cross Hospital established in Europe at St. Katherine s Lodge Regent s Park The hospital which will be for American and British officers stands in four acres of grounds and has been equipped for 40 orthopædic patients by Mr and Mrs William Salomon of New York Captain F Kidner of Detroit and Captain de Forrest Willard of Philadelphia, have been chosen as the nucleus of the medical unit under the general supervision of Colonel Sir Robert Jones The nursing staff will be American and a number of well known British physicians and surgeons have signified that their services for other than orthopædic work are at the disposal of the hospital

KING GEORGE S FUND FOR SAILORS —A special effort is being made to augment the funds of the various societies ministering to the needs of our sailors and their dependents under the auspices of King George s Fund for Sailors The *Daily Telegraph* has been particularly associated with this effort and has organised a campaign for making the appeal a national one representing all classes of society Lord Burnham points out a principal inducement to subscribe quickly in the fact that Christmas will bring the first distribution to the societies participating so that the Press will in reality be providing a Christmas present to our sailors The fund is not intended to interfere with subscriptions now being sent directly to the several institutions Amongst others the appeal is supported by Prince Albert the President of King George s Fund for Sailors Sir F Geddes First Lord of the Admiralty, Admiral Sir J R Jellicoe First Sea Lord, and Admiral Sir David Beatty, Commander in Chief of the Grand Fleet The *Daily Telegraph* has made a contribution of £500 to the first list of subscriptions Communications should be addressed to the *Daily Telegraph*, Fleet-street E C 4

Lieutenant-Colonel George Scott Williamson R A.M C, the pathologist to the Bristol General Hospital who went out into "No Man's Land" on August 26th with a stretcher company, is reported missing and there is little doubt that he is a prisener in Germany Colonel Williamson has been twice mentioned in despatches

THE SERVICES

APPOINTMENTS TO THE INDIAN MEDICAL SERVICE

IT has been announced in the Press that after the open competitive examination held in July 1915 for admission to the Indian Medical Service no similar examination would be held during the continuance of the war but that such appointments as might be required to meet absolutely indispensable needs of the Service would be made by nomination by the Secretary of State To assist him in making these appointments which as already announced will be limited in number to the absolutely indispensable needs of the Service he has appointed a Selection Committee who will summon and interview such applicants as may appear to be *primâ facie* suitable and make recommendations for appointment Applications for appointment should be addressed to the Secretary of the Military Department, India Office Whitehall S W 1 and should contain concise particulars of the applicant s medical degrees and career Applicants must be over 21 and under 32 years of age at the time of application Particulars regarding pay promotion &c. in the Service can be obtained from the Secretary Military Department

just after returning from a tour of duty behind the trenches His commanding officer writes of Captain Hardie's good work under trying and dangerous conditions He leaves a widow and two children

FRANCIS ARTHUR DERAVIN, M B, CH B MELB,

CAPTAIN AUSTRALIAN ARMY MEDICAL CORPS

Captain F A Deravin, who died suddenly on active service at the age of 41 years, was sixth son of the late J T Deravin and was born at Bendigo, Victoria, and educated at the High School Bendigo After graduating in medicine at the Melbourne University, he was for some years resident surgeon to the Fremantle Hospital, Western Australia, and on resigning this position visited London for a year of post-graduate work On his return to Australia he practised at Casterton Victoria, until taking up duty in the Australian Army Medical Corps He was well known in Australia as a keen exponent of all games of sport

MINISTRY OF NATIONAL SERVICE ITS MEDICAL ORGANISATION

In his speech at Nottingham on Oct 9th Sir Auckland Geddes outlined the new medical organisation, inaugurated by him at the Ministry of National Service, of which Dr James Galloway is chief medical commissioner

The New Recruiting Machine

The various professional bodies in the United Kingdom are being closely linked up in the construction of a new recruiting machine, with a medical advisory board at its head, to which they send representatives The country is divided up into a series of regions, each under a medical commissioner, who is provided by the responsible civilian medical organisation with a list of medical men of good standing in his area willing to serve on the medical boards The president of each National Service medical board is a whole time official of the Department and is a civilian approved by the medical advisory board He is assisted by a rota of local members, generally three at a time, who serve for a day or more in the week as is consistent with their work as medical practitioners The boards work to standards settled by the Department, the instructions laid down amount practically to a text-book of medical standards in the preparation of which Dr W Hale White has given much help The old categories, which were always administrative rather than medical in intention, have been done away in favour of four grades as follows (1) Men organically sound, of good mental capacity and muscular development and without any deficiency in their special senses (2) Men organically sound and capable of standing exposure but deficient in some special respect—e g, short-sighted deaf flat-footed, and so on (3) Men falling between grades (2) and (4) This grade is marked for whatever class of work the man is fit for (4) Men so unfit as to make it unfair to expect them to undertake strenuous work at all

Any man who has been examined by a National Service medical board and considers that he has new facts to bring before the board may apply for a fresh examination If he thinks he has been hardly treated by their decision he may refer to the lay appeal tribunal for a re examination If a *prima facie* case is made out he is then examined by assessors appointed to groups of tribunals by the Local Government Board in England and the Scottish Office Should the assessors find him unfit the Director of National Service accepts their decision as final

First Meeting of the Medical Advisory Board

The first meeting of the medical advisory board took place at the Ministry Windsor Hotel Victoria street on October 4th The board consists of the Chief Com missioner Dr James Galloway, C B who is the head of the Medical Department of the Ministry Sir Donald McAlister (General Medical Council), Mr J W B Hodsdon President Royal College of Surgeons, Edinburgh (Scottish Medical War Emergency Committee) Mr Charles Ryall (Committee of Reference of the English Royal Colleges) Dr T J Verrall and Mr E B Turner (Central Medical War Committee), Professor Arthur Keith, and Dr J Arnallt Jones Representatives of the Local Government Board, Scottish Office Naval and Military Services, and National Health Insurance Commission attended

Sir Auckland Geddes, who was in the chair, commented on the changed conditions under which medical examinations have to be conducted under the present compulsory military service as compared with those of the early days of the war when all those presenting themselves were volunteers Since the beginning of 1917, and especially since the Review of Exceptions Act, there had been, he said a great deterioration in both the willingness and the fitness of men called upon to undertake military service Medical boards had had to face in the past much abuse from persons who fostered unwillingness to serve and who took every chance which offered of discrediting the medical examination of recruits He went on to describe the abuses which had arisen under the old system Medical certificates of unfitness had been given on the scantiest evidence personation had been rife, and even members of boards had been influenced by unworthy motives to place a man unjustifiably in a low category 14,000 prosecutions had been instituted on charges connected with these abuses during the past 14 months The Minister described the plans of the medical department of the National Service Ministry as nothing short of a medical survey of the male population of military age in which he saw a scientific opportunity of great possibility Arrangements were being made by the Ministry for the supply of medical men to all the Government departments, as well as to deal with the shortage of medical students at the schools On all these matters the medical advisory board would be referred to for counsel and guidance, and Sir Auckland Geddes proposed to call upon it to enlist on his behalf the aid of the existing organisations of the medical profession in order that the Ministry of National Service might become a clearing house in correlating medical activities with the requirements of the nation at large and those of the Navy, Army, Air Board, Local Government Board, Pensions Ministry, Scottish Office and National Insurance Commission The work of nominating the medical boards had been, he said, referred to the Statutory Committees of the profession Sir Auckland Geddes concluded by stating that the work of preliminary organisation, as outlined above, is being rapidly accomplished, and that the new system will be instituted on Nov 1st

THE WAR RECORD OF THE LONDON MEDICAL SCHOOLS THE THIRD YEAR OF WAR

We have received the following revised returns concerning the war record of the Middlesex Hospital —

Joined the military branch of the Service, 374 Joined the naval branch of the Service, 47 Died, 24 Wounded, 38 Mentioned in despatches, 20 Prisoners of war, 3 Missing 2 Torpedoed, 3 D S O, 2 Croix Rouge Francaise, 1 Croix de Guerre, 1 Military Cross, 9

INDIAN MILITARY HOSPITALS

The hospitals receiving overseas cases have been brought steadily up to date, with modern medical equipment and the provision of electric light and fans Convalescent sections and depôts have been established for the reception of British and Indian soldiers discharged from war hospitals who no longer require in patient treatment Facilities exist for orthopædic and electro-therapeutic treatment of cases in hospitals at Bombay, Cawnpore Umballa and the Red Cross hospitals at Mussoorie and Dehra Dun British convalescent enteric depots have been opened for the segregation of this class of case during convalescence Lady nurses are employed in all British war hospitals in station hospitals of any size, and in Indian war hospitals at Bombay Poona Rawal Pindi Karachi Secunderabad, and Meerut

The St John Ambulance Association at Simla has issued a letter amplifying a proposal to expand the service of the Voluntary Aid Division in India. It is believed that there will be no difficulty in obtaining a number of suitable candidates prepared to qualify for work in hos pitals and prepared to give their services to supplement and assist the regular staff All the work to be done by such ladies would be voluntary, and those who participated in it would not be liable to transfer from one station to another Ladies willing to become hospital visitors or hospital nurses should be over 20 years of age and present certificates of proficiency in first-aid and home nursing

HOSPITAL TREATMENT OF THE INVALIDED SAILOR OR SOLDIER

Representatives of the honorary medical staffs of the voluntary hospitals of the County Palatine of Chester (and of some of those situate in the counties adjacent) and officers of the local Medical and Panel Committee met at Crewe on Sept 29th to confer on the position of the honorary medical staffs of voluntary hospitals in undertaking the care of invalided seamen and soldiers under arrangement with the Ministry of Pensions Dr J H. Marsh, of Macclesfield General Infirmary, chairman of the local Medical and Panel Committee occupied the chair The following resolutions were passed unanimously and it was decided to submit them to the consideration of the various hospitals concerned to the Ministry of Pensions, and to the county Pensions Committees —

That the services of the medical profession should not be given gratuitously to patients who are maintained by public funds

That from all payments received by the governing body of a voluntary medical institution from the State or local authority a proportion to be agreed upon between the governing body and the honorary medical staff should be placed to a special fund which shall belong to the honorary medical staff.

A scale of charges was also resolved upon, the chief items being as follows —

	£	s	d.
For major operation, including anæsthetist s and assistant s fees	7	7	0
For minor operation requiring general anæsthesia, including an anæsthetist s fee	2	11	6
The anæsthetist s fee (included in the above fees) where the assistant is not a salaried resident medical officer	1	1	0
For minor operation with local anæsthetic	1	1	0
For attendance on in-patients (after operation or otherwise) for each week	1	1	0

(For less than a week in proportion)

' OUR DAY "—Red Cross work is now said to be costing the country something over £6 a minute and next Thursday (Oct 18th) an effort will be made to collect a sum of money sufficient to enable the Red Cross to carry on its beneficent work on behalf of the sick and wounded Flags and emblems will be sold as usual on "Our Day' throughout the country several metropolitan mayors have opened supplementary subscription lists and social gatherings of various kinds will further the appeal. Helpers are needed particularly for the South African section Offers of assistance, gifts and suggestions will be welcomed by Miss C May Beeman, the organising secretary, 10 West Bolton Gardens, S W 5 —The Viceroy of India has fixed Dec 12th for ' Our Day in India —Americans in England are making a combined present to the British Red Cross Society for Our Day " and contributions for this purpose should be sent to Mr Clarence C Stetson care of The National City Bank of New York, 34 Bishopsgate London E C 2.

FIRST AMERICAN RED CROSS HOSPITAL IN EUROPE.—On Oct 4th Mr Page the United States Ambassador opened the first American Red Cross Hospital established in Europe at St. Katherine s Lodge Regent s Park. The hospital which will be for American and British officers stands in four acres of grounds and has been equipped for 40 orthopædic patients by Mr and Mrs William Salomon of New York. Captain F Kidner of Detroit and Captain de Forest Willard of Philadelphia, have been chosen as the nucleus of the medical unit under the general supervision of Colonel Sir Robert Jones The nursing staff will be American and a number of well known British physicians and surgeons have signified that their services for other than orthopædic work are at the disposal of the hospital.

KING GEORGE S FUND FOR SAILORS —A special effort is being made to augment the funds of the various societies ministering to the needs of our sailors and their dependents under the auspices of King George s Fund for Sailors The *Daily Telegraph* has been particularly associated with this effort and has organised a campaign for making the appeal a national one representing all classes of society Lord Burnham points out a principal inducement to subscribe quickly in the fact that Christmas will bring the first distribution to the societies participating so that the Press will in reality be providing a Christmas present to our sailors The fund is not intended to interfere with subscriptions now being sent directly to the several institutions. Amongst others the appeal is supported by Prince Albert the President of King George s Fund for Sailors Sir E. Geddes First Lord of the Admiralty, Admiral Sir J R Jellicoe First Sea Lord, and Admiral Sir David Beatty Commander-in Chief of the Grand Fleet The *Daily Telegraph* has made a contribution of £500 to the first list of subscriptions Communications should be addressed to the *Daily Telegraph* Fleet-street E C 4

Lieutenant-Colonel George Scott Williamson R.A.M C, the pathologist to the Bristol General Hospital who went out into ' No Man s Land' on August 26th with a stretcher company is reported missing and there is little doubt that he is a prisoner in Germany Colonel Williamson has been twice mentioned in despatches

Furness and G Furness Manchester J A. Hart, London Hospital M A R. Khalifa, Guy's Hospital J Kershaw and G L. Meachim, Manchester E Savage Cardiff and St Bartholomew's Hospital J H Sullaiman Guy's Hospital and H E Suter St Mary's Hospital a scheme and the absence of an established local authority a combined and permanent scheme cannot at present be seriously considered any scheme now proposed must deal only with liquid trade wastes He first deals with permanent works for the safe disposal of offensive trade refuse and then refers to the method adopted by one firm of distributing its wastes over limited areas of land and afterwards cultivating the ground with good results Although the land is waterlogged at a depth of 3 to 4 feet he is of opinion that with an amply increased area of land, and the systematic workings and cultivation of the land over which the liquid was essayed disposed of better results can be obtained This is only suggested as a tentative measure with a view to the immediate suppression of pollution. The trade wastes at present discharged into the river the most serious source of pollution should be diverted to the land for final treatment The effluent from a factory within the borough is also considered this effluent is different in character smaller in quantity and less offensive The matter has later come under the consideration of the Natal Fisheries Board and it was resolved that the Central Government should undertake the construction and equipment of a system of sewerage, without treatment providing for an outflow of sewage into the sea, and that the Central Government should reimburse itself by means of a sewerage rate to be imposed on the users of the system With the developments which may be expected in the district at the head of Durban Bay the question may become a large and complicated one and it was held that any scheme undertaken should provide for the future requirements of the district

From the above account it will be seen that a position of some difficulty has arisen in regard to fish conservation public health, and social amenities and it is to be hoped that a satisfactory settlement will be reached

WEIHAIWEI

Sir J H Stewart Lockhart, K C M G Commissioner of Weihaiwei—the territory leased to Great Britain by China in 1898—in his report recently received at the Colonial Office for the year 1916 states that the inhabitants (147,177) were as well behaved and industrious as usual and their health excellent In the hospital at Port Edward there were 7799 out patients and 192 in patients and the number of operations performed was 329 At Wenchuantang Hospital 3332 new cases were seen In the hospital on the Island of Liu Kung there were 2595 out patients and 22 in patients the total attendances were 6625 and 86 operations were performed During the year 5339 persons were vaccinated

The number of opium smokers certified by the Government medical officers to be persons whose life or health would be endangered by a sudden cessation of the use of opium was 36 as compared with 38 in 1915 the average age of the licencees being 60 The number of convictions under the Ordinance prohibiting the importation and smoking of opium was 63 as compared with 59 in 1915 The highest temperature was 96 F in June and the lowest 12° in December Rain or snow fell on 69 days The average rainfall in 16 years up to the end of 1916 was 29·43 inches the highest fall being 47 70 inches in 1914 and the lowest 15 76 inches in 1900

I O H asks Has any medical man seen or heard of harm resulting from the continuous administration of 0·5 gramme aspirin twice or thrice daily over a period of three months or more?

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention should be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only *and when accompanied by blocks it is requested that the name of the author and if possible of the article, should be written on the blocks to facilitate identification*

Letters whether intended for insertion or for private information must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor"

We cannot undertake to return MSS not used

Offices 423, STRAND, LONDON, W C 2.

Notes, Short Comments, and Answers to Correspondents.

A DOUCHE LAVATORY ON A MAN OF WAR

In the *Archives de Médecine et Pharmacie Navales* for August Dr Bellile, of the French Navy gives an account of the arrangement of the douche lavatory on board the French man of war *Amiral Charner* The old scheme in the French Navy was for the men to wash in buckets, one probably for each mess (There was an old saying in another Navy about the mess boy getting the first wash in winter and the last in summer, but those days are, of course, long past and gone) In 1902 an order came out that washing in buckets was forbidden, and that douche taps were to be fitted and supplied with warm water The wash places were, however, not fitted, not even in the new ships. Individual ships had some advances Thus a basin was served out to each man in the *Duguay Trouin* and a few other ships In 1909 again did the spirit of cleanliness stir at headquarters, and in 1911 Dr Bellile got an installation fitted in the *Amiral Charner* which became the pioneer ship The plant as described should be very effective From a tank on the deck overhead holding 2400 gallons, heated in winter by a coil of steam pipe, there are led two pipes to the compartment below, which can also be steam heated in winter The pipes are led in a U bend round the room and a discharge with a rose is fitted every 2½ feet The rose is made of copper so that it may not rust, and there are three holes (2 millimetres square) in the first, four in the second, and so on, to allow equal supply of water at each of the 35 roses The douches, which are highly approved by the men, scarcely use any more water than the former buckets used and take up no more room Moreover, it is much easier now for the sailors to keep clean

DISCHARGE OF EFFLUENTS FROM FACTORIES INTO DURBAN BAY

The position arising from the discharge of liquid trade wastes into Durban Bay is considered in the report of the Natal Fisheries Department for 1916,[1] both as regards the effect on fish life and from a public health standpoint This report relates the work of the department during the year under review, and gives full financial and statistical information (largely tabular) of the fishing industry in Natal, indeed, the whole report reflects the interest taken in developing and fostering this industry Mr Godfrey W Dick, principal fisheries officer and secretary to the Natal Fisheries Board, says that a certain measure of success has attended the enactment of protective measures and their energetic enforcement by the inspector so far as conservation of fish life in Durban Bay is concerned, but he is constrained again to record the strong opinion that the pollution which takes place at the head of the bay has reduced the value of the work of the department very considerably The position is engaging the serious attention of the Durban municipality, the Port Advisory Board, and Natal Fisheries Board

In an annexure to the report headed Clairmont Flats Nuisance " Mr J Fletcher, borough engineer and Dr P Murison medical officer of health relate the source of the trouble and suggest remedies The liquid trade wastes come from a chemical business and two sugar refineries near South Coast Junction outside the borough of Durban The considerable wastes from two of these concerns are conveyed by pipes and open channels and finally discharged on to a flat area of land about three-quarters of a mile from the head of Durban Bay The third business conveys its wastes direct to the Umhlatuzan River The trade wastes which are allowed to distribute themselves over the Clairmont Flats form in small depressions pools and in larger ones ponds extending over acres Recently one firm has made an effort to conduct the wastes into rectangular pits (over 150) thus limiting the area over which the wastes flow The subsequent decomposition of this highly putrescible material is associated with the evolution of most objectionable gases and vapours giving rise to discomfort and annoyance to the burgesses of Durban and having in a considerable number acted injuriously on their health This liquid trade waste is declared to be 40 times as strong as ordinary sewage It is stated that no process of final disposal can be accepted which does not provide for special preliminary treatment and that the question of final disposal through the sewerage system of the borough of Durban cannot be entertained It is concluded that the special treatment of liquid trade refuse combined with future treatment of the domestic sewage of this outside district can be more effectually and economically dealt with by sewage works provided within the district, and by which it is feasible to obtain a non putrescible effluent which could be safely discharged into the watercourses leading into the bay In a later report Mr Fletcher deals with tentative measures to abate the nuisance as owing to the area being sparsely populated the cost of

The Relations OF TUBERCULOSIS TO WAR CONDITIONS

WITH REMARKS ON SOME ASPECTS OF THE ADMINISTRATIVE CONTROL OF TUBERCULOSIS[1]

By ARTHUR NEWSHOLME, K C B, M D,
MEDICAL OFFICER TO THE LOCAL GOVERNMENT BOARD

THE disturbed distribution of population caused by the war renders it impracticable to give accurate local death rates for tuberculosis in either sex or for tuberculosis in men for the whole country Apart from such rates, the figures as to total deaths from pulmonary tuberculosis in England and Wales in recent years are, however, instructive The table below shows that, comparing the experience of 1913, the last complete year before the war, with subsequent years, the deaths from pulmonary tuberculosis increased by 1582 in the year 1914, by 4621 in 1915, and by 4490 in 1916, the third year of war

The increase was not confined to one sex Comparing recent years once more with 1913 male deaths from pulmonary tuberculosis increased by 778 and female deaths by 804 in the first year of war, male deaths by 2596 and female deaths by 2025 in the second year of war, and male deaths by 2204 and female deaths by 2286 in the third year of war

England and Wales

Year	Deaths from pulmonary tuberculosis			Deaths from other forms of tuberculosis			Deaths of persons from—		
	Males	Females	Total	Males	Females	Total	Pneumonia	Bronchitis	Influenza
1911	21 985	17,247	39,232	7,242	6 646	13 888	37 642	36 555	4 343
1912 ..	21,563	16 515	38,078	6 253	5 730	11 983	37 348	39 735	5 354
1913 ...	21 034	16 021	37 055	6 623	5 798	12,421	37 530	39,227	6,394
1914 ..	21,812	16 825	38,637	6,264	5,397	11 661	40 070	40,189	5 954
1915 ...	23 630	18 046	41,676	6 715	5 904	12 619	48,874	50,974	10 494
1916 ...	23 238	18 307	41 545	6 458	5 825	12,283	37 916	43 412	8,791

The increased mortality from pulmonary tuberculosis having been shared by both sexes it must be inferred that conditions arose adversely affecting the health of persons of both sexes in these years

It is natural to assume that the altered conditions of life during war time were concerned in producing this effect, but this hypothesis needs to be considered in relation to collateral experience of other diseases as shown in the above table

The teaching of this table is brought out in the following table in which the experience of deaths in 1913 under each disease is stated by the relative figure 100

England and Wales Relative Mortality in 1913 (= 100) and in Subsequent Years from Certain Disease

Year	Pulmonary tuberculosis	Influenza	Pneumonia.	Bronchitis
1913 ..	100	100	100	100
1914 ..	104	93	107	103
1915	112	164	130	130
1916	112	138	101	111

It will be seen that increased mortality from pulmonary tuberculosis was associated in 1915 and 1916 with still more excessive mortality from influenza. This association is no new feature It was seen markedly in the years 1890-91-92 and again in 1899 1900 The experience of 1915-16 is the third occurrence in recent years of this coincidence, and there can be no doubt that influenza is a most dangerous complication of pulmonary tuberculosis

It is noteworthy that the deaths from pulmonary tuberculosis in both 1915 and 1916 were 12 per cent in excess of those in 1913, but that in 1916 the deaths from pneumonia had ceased to occur in excessive numbers, while an excess in deaths from influenza and from bronchitis continued on a smaller scale than in 1915 Whether this justifies the conclusion that the influenza element in the causation of excessive mortality from pulmonary tuberculosis was shared in 1916 by special war conditions to a greater extent than in 1915 cannot be stated with certainty Probably both in 1915 and 1916 war conditions have borne an important part in the excessive mortality from all the diseases enumerated in the above table There has been inter communication between different localities on a much larger scale than in normal times, and catarrhal infections—including cerebro-spinal fever, as well as the above mentioned diseases—have been rife

It has been noted that the excessive mortality from pulmonary tuberculosis has affected both sexes In both sexes the conditions favouring this excess, apart from catarrhal infections, have probably been similar

Men in the Army and men and women in industrial employment, notwithstanding the efforts to minimise these results have been exposed to conditions leading to the spread of tuberculosis and to the calling into activity of latent disease. A large number of unrecognised or partially recovered consumptives have entered the Army or have been employed at high wages in munition and other works In many instances there have been overwork and excessive exposure to irritating dust Commonly also, owing to great migrations of military and civil population, there has been overcrowding under conditions unfavourable to health These are the outstanding facts They will need to be further considered in the light of the current year's experience

The experience in this country appears to coincide with that of the continental countries engaged in the present war In all of them, so far as can be gathered from official information, tuberculosis appears to have been more rife and more fatal than prior to the war It is proper to state that this unfavourable record would almost certainly have been worse but for the organised efforts to improve housing conditions in areas the population of which has been swollen by war work, and especially for the efforts made by the Government to secure improved conditions of work for munition workers as well as to cope with the special housing difficulties which have arisen I may draw attention furthermore, to the fact that notwithstanding the increase in the population of England and Wales in the interval, the deaths from pulmonary tuberculosis were fewer than in so recent a year as 1902

Tuberculosis and the war—In May, 1916, the Local Government Board, after consultation with the Army Council, circularised the local authorities concerned in tuberculosis schemes, asking them to arrange for their tuberculosis officers to assist the military authorities in the examination of recruits suspected to be suffering from tuberculosis The action taken in response to this appeal has been of material assistance to the military authorities

About the same time the Board issued a general Order extending their Tuberculosis Regulations and making it obligatory on every medical officer of health to send to the Army Council London, a list of all male persons between the ages of 18 and 45 who had already been notified to the medical officer of health as suffering from tuberculosis, and to keep the list up to date by the sending of weekly lists of newly notified males between the same ages to the Army Council By this means it has been possible for the Army Council to inform each Medical Board of the names of tuberculous men in their respective areas

REVIEW OF THE POSITION AS TO THE ADMINISTRATIVE CONTROL OF TUBERCULOSIS

In view of the association of war conditions with considerable increase of pulmonary tuberculosis it appears desirable to gives a summarised statement of the action specially directed in recent years to the control of tuberculosis Prior to 1911 excellent local work had been done in a relatively small number of areas in direct efforts to control the spread of tuberculosis in addition to the previous

practice is overworked, these conditions are not fulfilled. That they have not been fulfilled generally, apart from the war, is shown by evidence derived from many areas

Belated notifications —Notification is often delayed when the case has been recognised and for this, in some areas in which the medical officer of health or tuberculosis officer takes little useful action if any, after notifications have been received, the Public Health Authority may be held responsible In previous reports it has been repeatedly urged that notification depends largely for its completeness and promptitude on its being followed by action beneficial to the patient. It has no administrative value *per se*, its utility depends on the action which follows on notification. It is only when the medical officer of health the tuberculosis officer, and the medical practitioner coöperate in securing the patient's welfare, by improving the conditions under which he lives and works by measures of cleansing and disinfection, by safeguarding the health of the patient's family, and by a course of institutional treatment when this is indicated, that the possible utility of notification is realised

At present, cases of tuberculosis which have been under medical care sometimes are not notified until after the death of the patient, other notifications may be received by the medical officer of health within a few weeks or months of death, and the patient may have been ill, with symptoms which pointed to tuberculosis, for a year or two before his case is notified

The failure to notify is especially great for cases of non-pulmonary tuberculosis, and even when these cases are notified, often no systematic inquiry is made by the medical officer of health or the tuberculosis officer Systematic family inquiry in such cases not infrequently leads to the discovery of overlooked cases of pulmonary tuberculosis

Failure to notify may also be due to non recognition of tuberculosis by the medical practitioner in attendance This may be due to the medical practitioner being overworked It is often owing to the tuberculosis officer not being in touch with him and consequently opportunities for consultation have not been embraced If greater coöperation were the rule, a much higher proportion of cases would be recognised at the earlier stage when no sputum is available for examination and the tuberculous character of a large number of cases of chronic bronchitis' would be recognised

It is well known that failure to recognise a case of pulmonary tuberculosis until tubercle bacilli are detected in sputum implies that the disease has made considerable progress In my annual report for 1913-14 I gave figures illustrating the fact that even when there is sputum its examination as a means of diagnosis is utilised to a most variable extent in different towns Failing this examination a large number of cases of pulmonary tuberculosis continue for long periods to be treated as bronchitis

(3) *The tuberculosis officer* —Few of these officers had been appointed in 1912 but in June 1915 the number had increased to 238 most of them recently appointed During the last three years they have been largely replaced by part-time medical officers and the work has been reduced to a minimum The experience gained in the short time during which tuberculosis officers have been at work enables a number of points to be stated by way of indicating the lines for future development rather than of criticism of past work. The new service in some areas has been regarded with suspicion by medical practitioners and little use has been made of the facilities for consultation with the tuberculosis officer at the dispensary or elsewhere There was an insufficient number of doctors for the new service with adequate experience of the diagnosis and treatment of tuberculosis on modern lines and some of the less experienced did not secure the confidence and coöperation of private practitioners This condition which was unavoidable at first is only temporary

The medical officer of health is responsible for the execution of the work under the Board's Tuberculosis Regulations and his relation to the tuberculosis officer has not always been satisfactory This has often been due to the tuberculosis officer concerning himself with the treatment of the patient while giving little attention to his hygienic circumstances It is unnecessary to repeat remarks made in previous annual reports on this point, but one of the first tasks to be undertaken when normal conditions are resumed will be to secure more complete coördination of official tuberculosis work on its therapeutic and hygienic sides

The importance of examination of home contacts has been emphasised in past reports, but this work has not hitherto been developed to an adequate extent In some districts so far it has remained entirely in abeyance, and during the war the Board, in order to enable doctors to go on military service, have been compelled to inform public health authorities that this contact work may be intermitted

In some, especially in smaller, districts the medical officer of health has not carried out his duties completely under the Tuberculosis Regulations, and both from his standpoint and from that of the tuberculosis officer there is need of more complete coöperation than has hitherto been secured

What is needed is that the organisation of the tuberculosis dispensary shall be in close touch with the special work of the medical officer of health Both are concerned in home visiting and in supervision of the patient at home, and the visitation should be so arranged as not to be duplicated The extent to which the tuberculosis officer has succeeded in securing continuous touch with general practitioners has varied greatly in different parts of the country The early detection of cases of tuberculosis and their successful treatment with the regular supervision needed in their interests and that of their families, have followed naturally where the collaboration between general practitioner and tuberculosis officer has been secured

(4) *Sanatoria* —Pulmonary tuberculosis is the greatest cause of disablement and mortality in adult life It causes one-third of the total mortality during a large part of the working years of life. It is furthermore, a disease which is preventable For these reasons its selection for a special benefit under the National Insurance Act is justified in the interest of national efficiency Patients, especially workers suffering from tuberculosis call for treatment The only question is as to the most efficient methods of treatment. There is universal medical agreement on certain points. Open-air conditions of life, judicious feeding, and regulated rest and exercise or work are necessary to give the best prospect for the patient's recovery or improvement, and his hygienic training has a high value for the patient while greatly increasing the safety of those about him Even if the patient is not likely to recover, all will wish him to receive the treatment best directed to improve his health or failing this, medical assistance and nursing under favourable conditions during his progressive decline. The objects to be aimed at are cure of the patient, or if this is improbable his treatment under conditions conducive to his comfort, and securing others from infection Broadly speaking sanatoria are intended to fulfil the first condition hospitals the second to the extent to which treatment in a residential institution is required

These being the objects in view the question is whether sanatorium treatment as hitherto developed, has given the best results obtainable in the interest of patients and of the public The number of beds provided for the treatment of tuberculosis under schemes of public health authorities has doubled since 1911 These are supposed in the main to be sanatorium beds proper For the following reasons, however a high proportion of the patients in these beds have been of what is known as the hospital type as defined below

1st The largest number of cases coming under the care of general practitioners and of tuberculosis officers are cases of advanced disease or of chronic consumption in which complete recovery cannot be expected These cases press for institutional treatment, and it is difficult to refuse it even though the beds available are more suitable for patients in the earlier stages of disease The fact that a high proportion of these patients are insured persons claiming sanatorium benefit increases the difficulty under this heading Although Insurance Committees are entitled to refuse residential treatment for tuberculous insured persons and frequently do so on the advice of the tuberculosis officer there is a natural tendency to give this even when it is scarcely expected that improvement will follow

2nd. When such patients are received into a sanatorium there is a strong tendency for the medical officer to ask for repeated prolongation of treatment even when his better judgment would oblige him to certify that permanent benefit is improbable Not infrequently the same bed is occupied by a single patient for six or nine months who should have been replaced by earlier cases of disease requiring a shorter period of treatment and likely to receive permanent benefit general measures, such as improved sanitation, better housing, more satisfactory nutrition, and especially the hospital treatment of a considerable proportion of sickness generally, including a large proportion of the advanced cases of tuberculosis The important measures directed to the reduction of infection from bovine infection are not included in this analysis, but it may be noted that the final report of the last Royal Commission on Tuberculosis appeared in 1911, and that although the prevention of the possibility of human infection from cow's milk is still very incomplete, the pasteurisation or boiling of milk for human consumption is more generally practised than in the past The Milk and Dairies Act of 1914 will provide after the war the machinery for much more efficient control over bovine tuberculosis

The steps towards direct administrative control of tuberculosis may be summarised as follows —

Compulsory notification of Pulmonary Tuberculosis, Poor-law cases from Jan 1st, 1909

Compulsory notification of Pulmonary Tuberculosis, Hospital cases from May 1st, 1911

Compulsory notification of Pulmonary Tuberculosis, Cases in the general population from Jan 1st, 1912

Compulsory notification of all forms of Tuberculosis, Cases in the general population from Feb 1st 1913

National Insurance Act, 1911, Sanatorium Benefit, coming into operation, July, 1912

Finance Act, 1911, provided capital of £1,116,000 in England and Wales for erection of sanatoria

The Departmental Committee on Tuberculosis reported on April 3rd, 1912, that any scheme which is to form the basis of an attempt to deal with the problem of tuberculosis should be available for the whole community and that the organisation of schemes would best be undertaken by the county and county borough councils These recommendations were adopted by the Government, which undertook to provide out of the Imperial Exchequer one half the net annual cost of schemes for the general treatment of tuberculosis which were approved by the Local Government Board Following on the above, county councils and county borough councils were invited to formulate and carry into effect schemes for the provision of institutional treatment at dispensaries and in residential institutions, and such schemes have come into operation to a greater or less extent in most areas

The extent to which schemes for the treatment of tuberculosis have come into operation may be gathered from the following comparative figures In England in 1911 local authorities (other than Poor law authorities) had about 1300 beds for the institutional treatment of tuberculosis, while there were 4200 beds in private sanatoria and voluntary institutions In June 1916, the number of beds provided by public health authorities had increased to 6072, and voluntary beds to 5821 a total of 11,893 as compared with 5500 in 1911 In 1911 there were only about 25-30 tuberculosis dispensaries In 1917 this number had increased to 371 During 1912 and 1913 the Board's officers were engaged, with varying success, in persuading county councils and county borough councils to make a beginning with the formulation and establishment of tuberculosis schemes and in the detailed negotiations as to schemes put forward by the authorities who desired to proceed These efforts in the first half of 1914 were obviously becoming increasingly successful, but the declaration of war in August soon prevented further developments of tuberculosis work and seriously crippled and reduced the efficiency of existing work The curtailment and deterioration of the work already organised necessarily became more marked as the military demands for medical officers and for institutions increased

It may be stated generally that (1) In only a relatively small number of county areas have fairly completed arrangements for the institutional treatment of tuberculosis come into operation In most county boroughs deficiency of provision is less marked (2) Even when fairly complete arrangements have been made, these have usually been in full operation for a short period only, and have been crippled more or less during 1915 and 1916

A few county borough councils, who had organised sanatorium treatment prior to the passing of the National Insurance Act, form exceptions to these statements Much excellent work has been done under the dispensary and other institutional arrangements organised by local authorities, and many patients have been restored to health and a still larger number have had their working power partially or wholly restored, while the possibility of their continuing to be foci of infection has been minimised It must, however, be realised that the schemes of local authorities as a rule have only recently been initiated, that during the stage following initiation the progress made has been somewhat slow, and that this progress has been stopped to a great extent during the war The linking up of the different agencies required to secure the full benefit of the schemes, which was being gradually organised, has also been seriously retarded by the war

The tuberculosis arrangements are closely related in every particular to the work of public health authorities, and in each of the following paragraphs the closeness of this relationship will appear The difficulties and defects of the arrangements hitherto made are set out here with a view to future action directed to their removal

These difficulties and defects may be considered under the following headings (1) With relation to the patient, (2) with relation to the private practitioner, (3) with relation to tuberculosis officers, (4) with relation to sanatoria, (5) with relation to chronic and advanced cases of phthisis

(1) *The patient* —In normal times a large proportion of consumptive patients refrain from applying for treatment until disease is fully established and they are incapacitated for work Not infrequently this means that the patient does not consult a doctor until within a few months or weeks of his death This, in part at least, is due to the conditions of private practice for the mass of the population before medical benefit under the National Insurance Act came into operation and tuberculosis dispensaries were established. Prior to this, if the patient was not a member of a "club" the fee payable to a doctor discouraged the patient from seeking advice for what appeared to be a relatively trivial ailment

Education of the public as to the need to seek for advice for protracted coughs and colds or for other symptoms suggestive of the possibility of tuberculosis is badly needed, and until the working classes have realised the importance of the early diagnosis and treatment of catarrhs and tuberculosis and of the removal of the conditions (bad housing overcrowding, dusty indoor occupations, &c) which favour these, the arrangement for coördinated measures for the treatment of tuberculosis can have only partial success

Even when an insured patient is informed by his doctor that he is consumptive, delay in receiving sanatorium benefit is often caused because of the insured patient's unwillingness to go into an institution until his 10*s* weekly sickness benefit is about to be reduced to 5*s* Then he accepts a recommendation for sanatorium treatment In such cases it often happens that hospital treatment is really required

In the three years of the present war the temptations to neglect symptoms pointing to consumption have increased, as have also temptations to conceal the fact of the existence of consumption Many consumptives have felt impelled to take their part in the national work of the war A large number of recovered or partially recovered consumptives have been fighting as soldiers Although not a few of these have been able to withstand the strain of active warfare, the majority unfortunately have broken down, and their lives have been curtailed by the great adventure In many other instances unrecognised and latent tuberculosis has been brought into activity by the strain of a soldier's life, and the records already show that the war will be responsible for material national increase in tuberculosis, with a consequent increase in the death rate from this disease

The dearth of workers and the associated high wages have led to the employment of a large number of semi invalids in industrial life The temptation of the high wages has in many instances led both men and women to refuse sanatorium treatment or other systematic treatment

(2) *The private practitioner* —The medical attendance of the majority of patients in this country is organised under the conditions of private practice whether for insured patients or others It is to the private practitioner that most patients resort and the early recognition and treatment of disease depends primarily on his skill, on his not being so overworked as to be unable to devote adequate time to the examination of each patient coming under his care, and on his willingness to refer doubtful cases for consultation with the tuberculosis officer It is not surprising that under war conditions, when nearly every doctor remaining in civilian

But sanatorium treatment and, even more important, hospital treatment of consumptives on the lines indicated in previous paragraphs must form an essential part of a satisfactory programme for the treatment and control of tuberculosis

The Local Government Board's grants to local authorities for the institutional treatment of tuberculosis have not yet reached a quarter of a million of money in any one year If to this be added the sum spent on the institutional treatment of insured consumptives after deducting the contributions of insured persons and employers, the total cost borne by Government funds is certainly less than half a million sterling per annum This is apart from local expenditure

Housing and institutional treatment for tuberculosis cannot properly be regarded as alternatives They are necessary complements to each other, and there must be increased expenditure in both directions Housing is a problem in two divisions For the healthy and for the sick. Special housing in institutions is needed for the sick when the care which their condition requires is not available in the home of the patient This is true whether the patient will be cured by the institutional treatment or not But it is the duty of administrators so to arrange the conditions of admissions to and continued treatment in, institutions that the provision *will be used in the most economical and efficient manner* possible, consistent with the welfare of the patients concerned

STERILISATION BY DAKIN'S SOLUTION AND THE OCCURRENCE OF SECONDARY HÆMORRHAGE

BY E F BASHFORD, M D EDIN ,
CAPTAIN R.A.M.C
(*From a Surgical Observation Hut in France*)

SINCE the treatment of septic wounds is of prime importance and great improvements are being effected in it, no excuse is necessary for reinvestigation by a novel method of the relative potency of certain antiseptics which are fashionable at the present time An impartial judgment from time to time of the value of the methods in use and of others proposed proves of direct benefit to the wounded under treatment Such inquiries are indeed required to safeguard the patient against methods which although new or modifications of older procedures are not based on adequate trials and against methods which the wounded have seen described in the lay press and feel aggrieved at not receiving

Object and Nature of Present Inquiry

The ideal antiseptic has yet to be found, all those in use possessing certain disadvantages The present inquiry had its origin in the question of whether or not secondary hæmorrhage is more frequent under some forms of treatment at present in vogue than in others suspicion having been aroused that the walls of healthy vessels lying exposed in wounds might be corroded by the antiseptic solution employed The histological investigation of vessels from which secondary hæmorrhage had occurred has no lent support to this suspicion, as without exception, they were found to have suffered previous damage In a few cases the damage was purely physical and in one instance this physical injury was associated with an aseptic thrombosis In most cases septic thrombosis was present In yet others the bleeding point was surrounded by granulations showing that corrosion was not the cause of the hæmorrhage In another paper I have discussed the frequency of thrombosis in association with infected wounds [1]

Resort was had to experiment with chloramine Dakin's solution, Lorrain Smith's solution (eusol) and flavine For purposes of comparison parallel experiments were made with iodine and mercury perchloride

The method adopted consisted in the immersion of living tadpoles in various dilutions of the substances to be tested one advantage thus gained being the elimination of the question of soaking the skin with water such as occurs when watery fluids are applied to wounds The experiments were performed at a temperature of 24°-26° C The following observations were made

1 By snipping off the tail, some distance from the anus, and dropping it into broth, it was first ascertained that the skin of the tails of the tadpoles yielded a heavy growth of Gram positive and negative organisms—bacilli streptococci, and also coliform bacilli—and were therefore suitable for this investigation

2 The lethal concentrations of the several solutions for the tadpole were then determined, and the condition of the tails as regards sterility ascertained immediately after death, the nature of the lethal action being left out of consideration as immaterial

3 When a minimum dilution, sterilising the skin of the tail at death had been found, a new series of experiments was made to ascertain if sterilisation could be effected in non lethal solutions

4 Thereafter the minimum time required to sterilise the tails was ascertained, and then was compared with the time required to cause the death of the animal

5 Finally, the corroding or digestive action of the several solutions on the abdominal wall was noted

After the preceding necessary preliminary experiments had been carried out the whole series of observations could be combined simultaneously in a long series of beakers, each containing one or more tadpoles immersed in increasing dilutions of the substance or substances The accompanying tables give the results of such series of experiments

TABLE I —*Dakin's Solution (Diluted to give the Concentration of Hypochlorite shown in Column I)*

Dilution of hypochlorite	Average time required to cause death.	Condition of skin of tail at death	Minimum time required to sterilise skin of tail	Time required for abdominal wall to rupture
1 1 000	3 min	Sterile	3 min	35 min
1 2,000	6		3	3 hrs
1 : 4 000	12		5	4
1 10 000	18		5	44

[1] [illegible] Journal of [illegible] 7

Cases of pulmonary tuberculosis requiring treatment in a residential institution may be classified as follows —

"*Sanatorium cases*"—Cases in which permanent improvement or recovery can usually be anticipated

"*Hospital cases*"—Cases in which only temporary, though possibly prolonged, improvement may be anticipated.

The hospital group will include (1) Patients who may be expected to recover considerable ability to work, (2) patients admitted for a short term for educational treatment, (3) patients with advanced disease, many of whom improve greatly under institutional treatment, (4) advanced cases requiring continuous medical care and nursing Cases requiring special observation for the purpose of diagnosis or to determine the best form of continued treatment

Hospital cases are such in the sense that they are not admitted with a view to the possibility of complete recovery Probably they will improve under treatment, but recovery of permanent working capacity is not expected.

The duration of treatment required under each of the above headings varies greatly During the last five years a large number of patients with chronic and advanced phthisis have been treated under conditions especially suitable for sanatorium cases, and the treatment thus given has proved unsatisfactory as regards arrest of disease If in future the best results are to be obtained from treatment of consumptives in a residential institution the decision as to the form of treatment in each case must be made solely on the medical needs of the patient In the decision the hygienic conditions of the patient's home are necessarily considered, as if these are unsatisfactory both the patient and his family suffer But if, in addition, regard is had to other considerations, and patients are chosen for sanatorium treatment on other than medical grounds, sanatorium treatment is bound to continue to give relatively unsatisfactory results

(5) *The treatment of chronic and advanced cases of phthisis* —Under present conditions a high proportion of the patients coming under treatment for tuberculosis will not recover their health permanently or completely This being so it is well that treatment of such patients should be considered from the point of view of ordinary medical treatment Every patient is entitled to treatment, whether his illness be curable or not A local authority undertaking such treatment may have regard to economy, but on the merits this must not be secured at the expense of the patient Considered from the standpoint of the patient, the treatment of a considerable proportion of consumptives in residential institutions is most desirable This is especially true for patients who are acutely ill, or ill with advanced disease, and who cannot be satisfactorily nursed in their own homes

The question of treatment in residential institutions of patients suffering from phthisis at a probably incurable stage cannot, however, be considered solely from the standpoint of the patient's own interest Nothing should be done, and nothing need be done, contrary to these interests, but public and personal interests alike point to the desirability of treating the consumptive under conditions which will minimise the possibilities of acquirement of infection by contacts

For reasons of economy, as well as because of the unwillingness of patients to leave home, a large proportion of the infective lifetime of every consumptive and the whole of the lifetime of some consumptives will necessarily be spent at home Measures for securing that he shall not be a source of massive infection to others must be reconciled with this economic consideration Much can be done to secure this in connexion with domiciliary treatment or attendance at a dispensary, when associated with the oversight of the home conditions of patients But experience has shown that in such cases home supervision is much more efficient when preceded by a short term of stay in a sanatorium or hospital for tuberculosis in which the patient is trained in the hygienic and general management of his condition, including the proper use of sputum flasks, &c Unless he is suffering from advanced disease it is advantageous for him also to be trained during this time to sleep in a shelter, preferably one of a type which can afterwards be lent out to the patient to be slept in by him at home if sufficient open space is available near his home for this purpose Much of the value of this educational treatment may be lost if the patient is not kept under helpful supervision afterwards

At a later stage of disease, when the patient is unable to work or is bedridden, the necessity of continuous care and nursing arises For the majority of patients among the wage earning classes this can seldom be given satisfactorily at home The experience of large towns shows that such patients have during the last 20 years been attended to an increasing extent in Poor law infirmaries and in special institutions, and this treatment and simultaneous segregation of patients, who would otherwise have been nursed under unsatisfactory domiciliary conditions, must be credited as being largely responsible for the decline in the death rate from tuberculosis which has occurred during the same period, notwithstanding increasing urbanisation of the population with its associated relatively high mortality from tuberculosis

Happily it is becoming more generally appreciated that no scheme for the control of tuberculosis in an administrative area can be regarded as satisfactory which does not make provision on a considerable scale for the institutional treatment of advanced cases of consumption beyond what in most areas has been so far provided

Housing in relation to the prevention and treatment of tuberculosis —Not infrequently it is assumed that in the prevention of tuberculosis improved housing is an alternative policy to the provision of sanatoria and hospitals for consumption It is also suggested that sanatoria and hospitals may in a large measure be dispensed with in the treatment of consumptive patients The two points need to be considered together, inasmuch as measures for the treatment and prevention of tuberculosis are to a large extent identical An essential part in the prevention of the spread of tuberculosis consists in housing patients under conditions in which they will not spread infection When a separate bedroom is not already available this may be done by provision of an additional bedroom at home or by removing the patient to an institution In practice both plans are desirable, according to circumstances

Institutional treatment is needed when special sanatorium treatment is required or when the patient needs skilled medical attendance and nursing which cannot be obtained at his home Satisfactory treatment is extremely difficult to organise at home both for early and for advanced cases of consumption and although much may be done to improve home conditions, this difficulty will, in large measure continue to apply for a large proportion of the total population

Statements to the opposite effect are made without adequate consideration of the general facts as to national housing At the last Census 3,139,472 persons or 8 7 per cent of the total population of England and Wales were living in dwellings containing less than one room for every two persons, there being an excess of 780 776 persons in these dwellings on this basis Of the total population 2 580 814, or 7 1 per cent, were living in one or two-roomed dwellings, and 4 429 119, or 12 3 per cent of the total population, in three roomed dwellings Under these circumstances the impracticability of providing adequate and still more of providing separate bedroom accommodation for consumptive patients is evident Satisfactory family life even for a healthy family is difficult to maintain under the above conditions The conditions become dangerous when a sick person has also to be housed, intimate contact with whom is likely to infect others The problem, in large measure, has been solved for the acute infectious diseases by establishing isolation hospitals, and although these hospitals may not have completely fulfilled expectation in the amount of reduction of infection secured, they have done great work in this direction and have made themselves indispensable under modern social and industrial conditions

In the acute infectious diseases the onset of secondary cases occurs after a few days' incubation, in pulmonary tuberculosis there may be a latent period stretching over years, and cause and effect may be difficult or impossible to connect It is, however agreed that such infection occurs, that some persons and especially the young, more easily fall victims, and that even the more resistant may fall ill from tuberculosis when exposure to infection has been protracted or when, otherwise the infection has been in massive doses

The bearing of these facts on the institutional treatment of consumptives is obvious They cannot be institutionally treated continuously even if they were willing and there is no need for residential institutional treatment during a large part of their sick life, assuming that they follow out the simple instructions in which they have been previously educated, preferably in a residential institution

But sanatorium treatment and, even more important, hospital treatment of consumptives on the lines indicated in previous paragraphs must form an essential part of a satisfactory programme for the treatment and control of tuberculosis

The Local Government Board's grants to local authorities for the institutional treatment of tuberculosis have not yet reached a quarter of a million of money in any one year If to this be added the sum spent on the institutional treatment of insured consumptives, after deducting the contributions of insured persons and employers, the total cost borne by Government funds is certainly less than half a million sterling per annum This is apart from local expenditure

Housing and institutional treatment for tuberculosis cannot properly be regarded as alternatives They are necessary complements to each other, and there must be increased expenditure in both directions Housing is a problem in two divisions For the healthy and for the sick Special housing in institutions is needed for the sick when the care which their condition requires is not available in the home of the patient This is true whether the patient will be cured by the institutional treatment or not But it is the duty of administrators so to arrange the conditions of admissions to, and continued treatment in, institutions that the provision will be used in the most economical and efficient manner possible, consistent with the welfare of the patients concerned

STERILISATION BY DAKIN'S SOLUTION AND THE OCCURRENCE OF SECONDARY HÆMORRHAGE

BY E F BASHFORD, M D EDIN,
CAPTAIN R A.M C

(From a Surgical Observation Hut in France)

SINCE the treatment of septic wounds is of prime importance and great improvements are being effected in it, no excuse is necessary for reinvestigation by a novel method of the relative potency of certain antiseptics which are fashionable at the present time An impartial judgment from time to time of the value of the methods in use and of others proposed proves of direct benefit to the wounded under treatment Such inquiries are indeed required to safeguard the patient against methods, which although new or modifications of older procedures, are not based on adequate trials, and against methods which the wounded have seen described in the lay press and feel aggrieved at not receiving

Object and Nature of Present Inquiry

The ideal antiseptic has yet to be found, all those in use possessing certain disadvantages The present inquiry had its origin in the question of whether or not secondary hæmorrhage is more frequent under some forms of treatment at present in vogue than in others, suspicion having been aroused that the walls of healthy vessels lying exposed in wounds might be corroded by the antiseptic solution employed The histological investigation of vessels from which secondary hæmorrhage had occurred has not lent support to this suspicion, as, without exception, they were found to have suffered previous damage In a few cases the damage was purely physical and in one instance this physical injury was associated with an aseptic thrombosis In most cases septic thrombosis was present In yet others the bleeding point was surrounded by granulations, showing that corrosion was not the cause of the hæmorrhage In another paper I have discussed the frequency of thrombosis in association with infected wounds [1]

Resort was had to experiment with chloramine, Dakin's solution, Lorrain Smith's solution (eusol) and flavine For purposes of comparison parallel experiments were made with iodine and mercury perchloride

The method adopted consisted in the immersion of living tadpoles in various dilutions of the substances to be tested, one advantage thus gained being the elimination of the question of soaking the skin with water such as occurs when watery fluids are applied to wounds The experiments were performed at a temperature of 24°-26° C The following observations were made

1 By snipping off the tail, some distance from the anus, and dropping it into broth, it was first ascertained that the skin of the tails of the tadpoles yielded a heavy growth of Gram positive and negative organisms—bacilli, streptococci, and also coliform bacilli—and were therefore suitable for this investigation

2 The lethal concentrations of the several solutions for the tadpole were then determined, and the condition of the tails as regards sterility ascertained immediately after death, the nature of the lethal action being left out of consideration as immaterial

3 When a minimum dilution, sterilising the skin of the tail at death had been found, a new series of experiments was made to ascertain if sterilisation could be effected in non lethal solutions

4 Thereafter the minimum time required to sterilise the tails was ascertained, and then was compared with the time required to cause the death of the animal

5 Finally, the corroding or digestive action of the several solutions on the abdominal wall was noted

After the preceding necessary preliminary experiments had been carried out the whole series of observations could be combined simultaneously in a long series of beakers, each containing one or more tadpoles immersed in increasing dilutions of the substance or substances The accompanying tables give the results of such series of experiments

TABLE I —*Dakin's Solution (Diluted to give the Concentration of Hypochlorite shown in Column 1)*

Dilution of hypo chlorite	Average time required to cause death	Condition of skin of tail at death	Minimum time required to sterilise skin of tail	Time required for abdominal wall to rupture
1 : 1 000	3 min	Sterile	3 min	35 min
1 : 2,000	6		3 "	3 hrs
1 : 4 000	12 "		6	4
1 10,000	18 "	"	5 "	44 "
1 25 000	30 "	"	10 "	Action absent
1 50 000	35	"	16 "	
1 100 000	60		30 "	"
1 : 500 000	Alive after 24 hrs	Sterile after 4 hrs	—	
1 : 1 000 000	"	Not sterile after 24 hrs	—	"

TABLE II —*Eusol (Diluted)*

Dilution of hypo-chlorite	Average time required to cause death	Condition of skin of tail at death	Maximum time required to sterilise skin of tail	Time required for abdominal wall to rupture.
1 : 2 000	5 min	Sterile	2 min	5 hours
1 : 4 000	6 "		3 "	Action absent
1 10 000	8		4 "	"
1 : 25 000	16		5	
1 50 000	35		12	"
1 100 000	60		30	
1 500 000	Alive after 24 hrs		—	"
1 1 000 000		Not sterile after 24 hrs	—	"

TABLE III —*Chloramine*

Dilution of antiseptic	Time required to cause death	Condition of skin of tail at time of death	Minimum time required to sterilise skin of tail	Time required for abdominal wall to rupture
1 : 50	18 min	Sterile	3 min	No appreciable solvent action
1 : 100	25	"	6	
1 : 200	35		10	
1 : 400	45		15	
1 1 000	1¼ hrs	"	25 "

Results of Experiments

A comparison of the tables shows that Dakin's and Lorrain Smith's solutions (Tables I and II) are practically parallel both in their lethal effects and in their power to sterilise living tissue, the latter action taking place in, roughly, half the time required to produce death, but that the solutions differ in their power to digest dead tissue Although in the table eusol is shown as digesting the abdominal wall in five hours, it should be noted that the effect was in no way comparable to that obtained with the highest dilution of Dakin's solution having this action In higher concentrations of Dakin's solution the tadpole, after dying, was speedily reduced to a little heap of sand representing the intestinal contents but with eusol this result was not obtained

Chloramine (Table III), by comparison with Dakin's solution and eusol, is shown to be relatively less toxic to the animal and the minimum time required to sterilise the tail is a much smaller fraction of the time required to kill the animal, being roughly ¼ contrasted with a ½ for the former substances These three preparations have, therefore, the common property that lethal action and bactericidal effects exercised upon the surface can be separated

Flavine (Table IV), or to be quite correct the two samples examined, has not the same power to sterilise the skin of the tadpole's tail The figures given in the table were the best obtained in four series, sterilisation having been obtained only once at death by a dilution of 1 in 2000

Iodine (Table V) and mercury perchloride have only been tested for the purposes of control, because, so far as I am aware, the method employed has not before been applied to a comparison of antiseptic power For iodine it may be noted that it is efficient—a point of interest—because it is so extensively employed as an application to the skin of the wounded, as well as in other circumstances Mercury perchloride calls for no comment beyond a reference to the figures (Table VI) as ascertained. The only point of interest in the present connexion is that with these substances lethal action and bactericidal power coincide in the higher dilutions This is also the case for the strongest concentration of flavine, bactericidal power and lethal action not being separable

Limitation of Corroding Action

As the question of the corroding action of Dakin's solution on the walls of healthy vessels has been raised in connexion with secondary hæmorrhage, and is one of importance, a series of experiments have been made on this subject It is well to show how this deleterious action can probably be excluded by the present observations

The anterior abdominal wall of the tadpole is a delicate membrane formed mainly of two layers of cubical cells Normally the intestines do not show through the anterior abdominal wall, whether in the living or newly dead tadpole, but in the event of a corroding or digestive action, the wall thins and they soon begin to be visible Finally, rupture of the abdominal wall is indicated with great exactness by the intestines being set free and shooting out, somewhat like a watch spring released A tadpole having been killed by immersion in water in which a trace of chloroform had been shaken up, was put into a beaker of hypochlorite solution simultaneously with a live tadpole of the same size, and the time required for digestion of the abdominal wall noted in the two cases Results such as the following were obtained —

Dakin's Solution

Dilution of hypochlorite	Time for abdominal wall to rupture	
	Tadpole immersed when dead	Tadpole immersed when living
1 1000	30 minutes	40 minutes
1 2000	2¼ hours	3 hours
1 : 4000	3 hours 40 minutes	3 hours 55 minutes

In such an experiment the action of the solution on the abdominal wall while the circulation remains intact for some time is contrasted with its action on the same delicate and still living membrane after the services of the circulation have been impaired or entirely lost The differences between the time required for the abdominal wall to rupture in the living and the dead animal respectively are larger than the interval required to produce death, as shown in column 2 of Table I[2], and hence the vitality retained by the skin immediately after death of the animal offers resistance to the digesting action of the fluid Moreover, if living tadpoles be compared with those that have been kept in water for an hour after death, the difference is greatly increased, showing that the more vitality is impaired, the more readily the tissue is attacked, and probably that dead tissue is immediately attacked Therefore the activity of the circulation and the retention of local vitality place limitations on the corroding action of Dakin's solution, while on the other hand the absence of a circulation and reduced vitality promote this action

It would appear from the above table as if the local action of Dakin's solution was held in check by an efficient circulation either by providing protein containing fluid or by carrying off and rendering harmless the hypochlorites as they approach living tissues without entering into combination with them—i e, killing them It seems reasonable to infer from experiments with such a delicate membrane that equilibrium between the two processes is well established within an extremely narrow zone of tissue—in this case two layers of cubical epithelial cells—and is an expression of the limited extent to which Dakin's solution, owing to its great lability or chemical instability can penetrate or injure living tissue in the presence of an efficient circulation

---

[2] Death occurred for 1 : 1000 in 3 and for 1 : 2000 in 6 minutes for 1 4000 in 12 minutes The differences are therefore 7 and 23 minutes respectively for the first two dilutions The approximation of the times for the living and the dead tadpoles shown in the above table is characteristic of all reactions taking place in the extremes of dilutions at which they occur a all and may be left out of the argument except in so far as the table shows on the whole that if action on living tissue does not commence during complete vitality still an impairment of vitality by the solution itself cannot be excluded and that the solvent action is probably being attempted all the time and becomes efficacious immediately whenever the impairment short of death becomes sufficient. Further observations are in progress on the action of the hypochlorites on the web of the frog's foot both when the circulation is active and arrested

This lability has been urged as a disadvantage and certainly the necessity for repeatedly renewing the supply of the solution is a practical inconvenience, but the very lability of the hypochlorites is probably the essence of their efficacy in wound treatment as contrasted with antiseptics of known stability, and it still remains to be proved that the application of hypochlorites through other than watery media is equally efficacious, as in their application by means of the oily media now undergoing trial and which it is hoped may act as reservoirs parting slowly with the active ingredient and therefore not requiring frequent renewal

The other substances as tested are devoid of this solvent action on dead tissue which, unless of the highly delicate and easily balanced nature characteristic of Dakin's solution may readily be dangerous as in the case of the ferments The abdominal wall of a living mouse is rapidly digested by 1 c.c of a 1 per cent suspension of Fairchild trypsin, so that the intestines lie free from the cavity in a quarter of an hour whereas 30 times this quantity of trypsin is borne without any evident effect when injected intravenously

Secondary Hæmorrhage

I have heard different opinions expressed as to the manner of action of Dakin's solution The foregoing observations seem to make it clear that in a septic wound it acts both as an antiseptic and as a cleansing agent or remover of dead tissue liable to serve as a nidus for micro-organisms The latter are caught as it were, between two fires, the antiseptic action of the hypochlorites on the one hand, and the natural defences of the living tissues with which they are brought in direct contact on the other It may of course, be a disadvantage to remove, say all healthy fibrinous exudate from the surface of the wound, but this is more than counterbalanced by the removal of all dead tissue The removal of dead tissue is extremely well exhibited in a case brought to my notice by Captain F L A. Greaves R.A.M C The anastomotica magna had been ligatured in an open wound and the visible free end, under the action of Dakin's solution began to show signs of disappearing so that the occurrence of secondary hæmorrhage was feared Nothing of the kind happened, however the erosion stopping just before the point of ligature was reached

Were the erosion of sound vessels the usual cause of secondary hæmorrhage this accident would occur in practically all cases The evidence adduced above to the effect that erosion of the delicate epithelial membrane covering the abdomen of the tadpole is resisted by its local vitality may legitimately be taken as evidence that the same holds for man in view of the experience gained in the treatment of wounds Part of the frequency of secondary hæmorrhage may be due not to the action of the solution but only to its improper application say by pressure of the point of the Carrel's installation tube badly applied and thus leading to injury Where however secondary hæmorrhages are common or gross or obvious septic thrombosis can be excluded the accident should be regarded rather as an indication that the surgeon to-day can preserve wounded limbs damaged to such a degree that earlier in the war either the wounded man died or the limb was amputated. Even the most careful cleansing now habitually carried out may fail to detect small injured or infected vessels with or without thrombosis from which the bleeding apparently almost always arises The position in regard to secondary hæmorrhage appears to me to be very similar to that attending the occurrence of local tetanus or the more familiar post-diphtheritic paralysis Both the latter accidents are met with as a result of successful attempts in saving life

During the war much has had to be learned as to dressing or treating septic wounds as contrasted with those of intentional surgery, and although the goal has not yet been reached great progress has been made so far as one who is not a surgeon, although constantly observing wounds at a general hospital and a surgical observation hut can judge

Victor Hugo writing of events supposed to have taken place in 1832, tells us 'The dressings were complicated and difficult and it was not without difficulty that chloruretted lotions reached the end of the gangrene (Les Misérables), and perhaps had the beneficial eras of antiseptic and aseptic surgery not for the time banished such wounds as Victor Hugo alludes to we should have been better prepared for the proper application of the hypochlorites or have already obtained improvements on them

(Continued at foot of next column)

(Continued from preceding column.)

It would have been impossible for me to perform the numerous simple but tedious experiments of which examples are given without the able assistance of Private T C Reynolds R.A.M C In conclusion I have to thank Colonel H E Cree, A M S for granting me facilities for carrying out this investigation

THE RETRACTION OF BLOOD-CLOTS,

WITH TWO METHODS FOR SECURING A LARGE YIELD OF SERUM

BY W D'ESTE EMERY, M D B Sc LOND
CAPTAIN R.A M C (T) DIRECTOR OF THE LABORATORIES KING'S COLLEGE HOSPITAL.

I THE EXTERNAL FACTORS

IN spite of the large amount of work that has been directed to the study of the coagulation of the blood, comparatively little attention has been attracted to what is in reality a part of the process—namely, the retraction of the clot by which the serum is squeezed out The question is of much theoretical interest, and now that so much use is made of serum in diagnosis and treatment, of some practical importance. In this and a subsequent article I propose to discuss the theory of the process, and to describe two methods by which a very full crop of serum may easily be obtained

The Process of Retraction of the Clot

The main phenomena are well known

Blood when drawn from the living body, and collected in a non living vessel, clots after a longer or shorter time At first the clot is a uniform, soft, mass After a period which varies from a few minutes to several hours, it usually begins to contract and in doing so squeezes out from itself a larger or smaller amount of serum, mixed, in most cases, with red corpuscles and leucocytes This serum usually makes its appearance in two situations—between the clot and the sides of the vessel, and on the surface of the clot—where at first a few small drops of serum appear, which, by their coalescence, form ultimately one or more large drops, or a complete layer of fluid The clot is heavier than the serum, and tends to sink, so that when the process is completed it forms a dark purplish mass, having approximately the shape of the containing vessel lying at the bottom of a greater or smaller amount of serum

When clotting takes place a fine network of filaments of fibrin is formed enclosing within its meshes serum red corpuscles and leucocytes This is the first stage of the process or coagulation In the second stage or retraction each filament tends to contract, and when it can do so successfully the serum and some of the red corpuscles are squeezed out, and a firm mass of fibrin containing a comparatively small number of red corpuscles is left The leucocytes I may add, almost certainly make their way through the clot by their own active movements the serum and red corpuscles are of course, squeezed out mechanically.

A little consideration will show that the effects of this contraction of the fibrin filaments will differ fundamentally in the centre and at the periphery of the clot If we consider a point in the centre of the clot (say a red corpuscle surrounded by a network of fibrin) we shall see that it is exposed to equal and opposite tensions in all directions and as a result there is a general raising of the pressure in the mass but no tendency for the movement of the serum or of the corpuscles in any one direction rather than in another, just as a sponge lying at the bottom of the ocean and permeated with water under high pressure will be neither compressed nor expanded Retraction therefore must commence at the periphery—either at the sides of the vessel or at the surface of the clot Here the conditions are quite different Consider the case of a point lying in contact with the wall of the vessel It also will be pulled on by fibrin filaments but not in all directions Those filaments which lie parallel to the surface in their contraction will have exactly the same effect as would be exerted by a stretched membrane surrounding the clot tending to compress it and make it smaller Those which are not parallel to the surface are either vertical thereto in which case they tend to pull the clot away from the containing vessel or at an angle, in which case they can be divided into their horizontal and vertical components one tending to make the clot contract the other pulling it away from the glass At first these tensions are balanced by the adhesion of the clot to the wall of the vessel, and if this is sufficiently firm retraction will never take place , if not, the clot first detaches itself from the surface, and then continues to contract At the upper surface there is no such counterbalancing pull, so that it is more easy for contraction to take place , hence we see, as a rule that serum appears first on the free surface, especially in large clots As a rule, however, not much fluid appears in this situation It is noteworthy, also, that there is usually a decided difference between the serum which appears on the top and at the sides of the clot, that in the former situation being turbid from red corpuscles, that in the latter being quite clear The reason for this difference is obvious When the blood is drawn the corpuscles immediately begin to settle and by the time clotting has taken place (unless this is very unusually rapid or unless the corpuscles sink with unusual slowness) there is a layer of corpuscle free plasma on the surface, and when this clots it interposes a barrier which allows the escape of serum, but not of corpuscles

Under certain circumstances (rapid settling of the corpuscles or slow coagulation of the blood) a thick layer of plasma may be formed before coagulation occurs In this case the clot that forms may be so firm that not even serum is squeezed out But here, I think, other factors may come in

A similar process takes place in the walls of the lower part of the clot as retraction proceeds The fluid that is squeezed out at the beginning of the process contains very many corpuscles, but as it continues these become less and less numerous, until at last only pure serum escapes This is obvious on careful examination, and I have corroborated it by actual count Here it is easy to see that the corpuscles which have been entangled near the surface will escape very easily, and in doing so leave a relatively firm mesh impassable to corpuscles, though permeable to serum After a time all the corpuscles which have passages open to them will have escaped and the sides of the clot will become to all intents and purposes similar to the non corpuscular layer at the top of the clot That this is the case may be shown by cutting a section of a clot in which complete retraction has taken place

Consideration of External Factors

I will now consider the factors which cause a difference in the retraction of different clots—why some retract quickly and give an abundant crop of serum, and some do so slowly, giving a smaller crop, or fail to retract at all

Two sets of factors have to be considered The first which I shall call the internal factors, are those which differ in different specimens of blood The second, the external factors, which I shall consider are the size and shape of the containing vessel, the nature of its walls, temperature, and gravity These are the main factors which we can alter more or less at our disposal, and in doing so cause great alterations in the process This paper deals with these external causes alone

(1) *The Shape and Size of the Vessel*

Reverting to our idea that the contraction takes place at the surface of the clot, which behaves as if it were enclosed in a slightly stretched elastic membrane theory shows what experiment clearly proves, that these factors are of prime importance This has not, I think been previously recognised In dealing with ordinary surface tension such as is always present at the surface of a liquid, it is a well known law, based on simple mathematical considerations that in the case of curved surfaces the smaller the sphere of which they form part the greater the tension the tension per unit being constant Thus if two soap bubbles of different size are connected the one with the other by means of an open tube the smaller will continue to contract (blowing out the larger one as it does so) until it forms a flat diaphragm across the tube

The force tending to draw the clot away from the surface is largest in small tubes and gets progressively less in larger tubes, reaching its minimum in a vessel with flat walls, in which the retraction commences and is most marked at the angles

In these experiments I have used human blood drawn directly from the veins This has been collected in a tube lined with paraffin, in which it will keep unclotted for a sufficiently long time for the experiments to be made Measurements, where necessary, are made with paraffined pipettes The following may be quoted as a proof of the effect of the size of the tube on the process The same specimen of blood was divided into eight tubes, two capillaries having an internal diameter of a little more than 1 millimetre, two narrow tubes having an internal diameter of about 4 mm , two "Wassermann" tubes with an internal diameter of 9 mm , and two test-tubes of 17 mm The results were as follows —

Diam of tube	½ hour	1 hour	2 hours	4 hours	24 hours	Yield of serum
17 mm	No retraction	No retraction a little serum on the top	No change	No change	No change.	0% except for a little at the top.
	,	,,				
9 mm	No retraction	No retraction	No retraction a little serum on the top	Slight retraction	Marked retraction	21·5%
		,		Nil	Slight retraction	6 3%
4 mm	No retraction	Retraction just obvious	Much	Much	Much	30 7%
,		No retraction			,	29·2%
Capillary rather more than 1 mm	Abundant retraction	Abundant retraction	No obvious alteration	No obvious alteration	No obvious alteration	56·0%
,		–			,	59·6%

Room temperature throughout

As a result of a considerable number of observations I can make the following statements with regard to specimens kept at the room temperature 1 Blood collected in capillary tubes always contracts completely, yielding the full theoretical amount of serum In most cases it commences in less than 15 minutes and is complete, or nearly so in another 15 2 In the tubes such as I use for Wright's collecting capsules, which have an internal diameter of 3-4 mm , retraction almost always takes place and is usually complete, or nearly so, but it is occasionally only partial and is always decidedly slower than in capillaries 3 In Wassermann tubes retraction is the rule, but there are occasional exceptions It is much slower and not as a rule complete in less than 12-24 hours 4 In large test-tubes it is very frequently absent and is always slow and often incomplete

The practical application of this is that where a good crop of serum is required the blood should always be collected in tubes as small as is convenient

(2) *Influence of the Nature of the Walls of the Vessel*

If this is of such a nature that the fibrin filaments can attach themselves firmly thereto, much of the force of their contraction (which I believe can only act for a limited time) may be expended in tearing the clot from the wall with the result that but little serum will be squeezed out In dealing with glass vessels of ordinary cleanliness I do not find this is a factor of any great importance and I have never yet found any medium which is sufficient to prevent the retraction of the clot from the walls of small tubes provided the proper temperature is employed In general the cleaner and newer the vessel the easier and quicker is the retraction , it takes place best of all in tubes that have recently been drawn out and in a tube that has been dry sterilised whilst not quite clean it may be appreciably delayed

In the course of a search for some material from which the clot would not detach itself at all I have had the best results with paraffin A tube lined with hard paraffin and allowed to set will often show no trace of serum long after complete separation has occurred in an ordinary tube I shall show subsequently how this fact is used in procuring a large and quick yield of serum

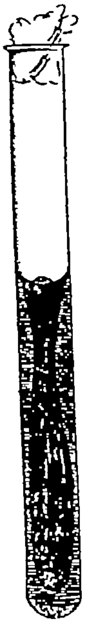
I do not think a clot formed in a living vein retracts from the walls I have never seen any unmistakable indication of this in sections of thrombosed veins and have not found it to occur in some observations I made in vessels in amputated limbs When separation of the clot, with resultant embolism takes place, I believe it is always due to a partial liquefaction of the clot by the trypsin given off by the polynuclear leucocytes—or of course, it may be separated by violence

(3) *Effect of Gravity*

If a freshly formed clot be suspended in air, the process of expression is very rapid the contraction of the fibrin being assisted by the weight of the serum, which tends to run out, just as water would do from a suspended sponge But if the clot remains in the serum this assistance from gravity is very much less, and at first sight it may not be apparent how it is brought about at all, for the serum within and that outside the clot have, of course, exactly the same specific gravity, and that within will have no tendency whatever to drain away

Two cases may be considered In the first, which usually occurs in comparatively narrow test-tubes, the clot remains adherent by a "rim of attachment" at its upper angle of contact with the wall of the tube, retraction always begins at some point on the side, and extends until every point except this rim of attachment has detached itself from the glass If we study such a clot (Fig 1) we shall see that it has a wide top, a comparatively narrow neck, and a wider base which is often almost or quite as wide as the tube, and may in some cases be almost spherical The shape is due to the action of gravity on a soft mass, originally cylindrical, which is lifting itself up by the contraction of its surface membrane The narrow neck is, of course, due to the stretching by the weight below whilst the rounded shape of the base is due to the fact that all stretched membranes tend to assume a spherical form

FIG 1



It surprises many to whom this phenomenon is first pointed out to realise that the very delicate rim of attachment should support the whole weight of the clot, but a little consideration will show that this is not really remarkable When the clot is first formed it has, of course, the specific gravity of the whole blood (about 1056) As soon as retraction commences it begins to rise, some of the serum, which is lighter (sp gr 1030), escapes At first the pull on the rim of attachment is practically nil As the clot shrinks its specific gravity gradually rises, ultimately reaching something just under 1100 At this point it will only weigh, whilst in the serum as much as if it has a specific gravity of 1100 – 1030, or 70 The force of gravity which helps to squeeze out the serum is never more than would be exerted on a cylinder of this specific gravity, suspended in air It does help the process somewhat, as is shown by the narrow neck of the clot from which the serum must be pretty thoroughly expressed The slight weight of the clot whilst suspended in serum may be understood when we realise that the contraction of the fibrin filaments will be quite sufficient to lift a large clot bodily from the bottom of the tube

If we cautiously insert a narrow pipette doing as little harm to the rim of attachment as possible, and pipette off the serum, the clot will regain its full weight so that the upper part will be forcibly stretched, and there will in addition, be the direct action of gravity on the serum in the clot The most efficient method by which we can assure gravity is by pipetting or drawing off the serum as fast as it is formed

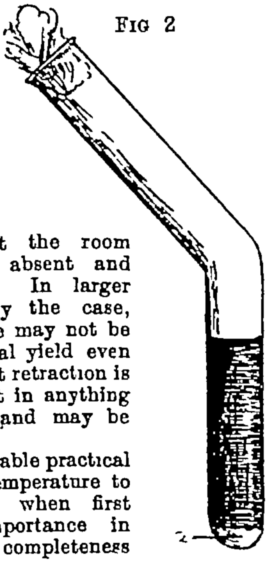
In the second case, which usually occurs in large vessels, the rim of attachment will not hold and the clot sinks to the bottom This is because the length of the rim increases only proportionately to the diameter of the vessel whereas the weight of the clot rises in proportion to its cube Here gravity helps in that the upper part of the clot presses on the lower, and tends to press out the serum, but the conditions are much less favourable for, firstly, the clot may be pressed against the walls of the vessels and the serum be thus prevented mechanically from escaping, and secondly, the compressing force exerted by the upper part of the clot tends to counteract the contraction of the lower part Of course if the clot does not separate itself from the walls of the vessel at all it may be necessary to separate it mechanically by means of a sterile wire, but where it can be avoided it is best not to do so, it is much better to leave the clot attached at the upper rim as long as possible and to pipette the serum off as soon as it appears

(4) *Effect of Temperature*

This is of the highest importance, and in general terms it may be stated that the nearer the temperature of the vessel to that of the body the quicker and more complete will be the retraction I have stated that every specimen of blood that I have ever seen has retracted at room temperature when kept in tubes about 3-4 mm in diameter, though the retraction is not always complete and is usually slow Retraction at incubator temperature is always rapid and complete In tubes about 1 cm in diameter retraction always takes place in the incubator, and is usually complete, at the room temperature it is sometimes absent and usually slow and incomplete In larger tubes this is very frequently the case, and even in the incubator there may not be anything like the full theoretical yield even after 12 hours In the ice chest retraction is usually absent or but very slight in anything larger than a capillary tube, and may be incomplete in these

Another point of very considerable practical importance is this it is the temperature to which the blood is exposed when first drawn that is of chief importance in determining the rate and completeness of the retraction, and in some cases the effect of exposure to an unsuitable temperature at this period cannot be afterwards undone

FIG 2



In Figs 2, 3 4 and 5 *a* represents the paraffined surface

One or two examples must be quoted —

(1) A specimen of blood in a paraffined tube was divided into two Wassermann tubes One was placed at once in ice water, kept there for half an hour, and subsequently kept at the room temperature It showed no retraction in 1¼ hours, and next day the percentage of serum present was 13 In the control tube, which was kept at room temperature throughout retraction was well marked in a quarter of an hour and in 48 hours the crop of serum was 34 6 per cent

(2) In a similar experiment four tubes were used, two of which were incubated 1 hour and then kept at the room temperature These gave 56 6 per cent and 50 per cent of serum (The blood was from a slightly anæmic person) Two other tubes were kept at the room temperature through out They gave 41 6 per cent and 34 6 per cent respectively

(3) In this experiment two Wassermann tubes of blood were incubated from the first, two kept at room temperature for 1 hour, then incubated, and two kept on ice for 1 hour, and then also incubated The following table shows the rapidity and completeness of the retraction —

—	½ hour *	1 hour	2 hours	Yield of serum after 3 hours
Incubated from the first	Retraction nearly complete	Apparently complete.	No change	53 3 % 56 6 %
Room temperature 1 hour then incubated	No retraction	No retraction	Much retraction	51 7 % 51·7 %
Ice-water 1 hour then incubated	No retraction	No retraction	No retraction Marked retraction	10 0 % 18 1 %

* Not counting the first hour

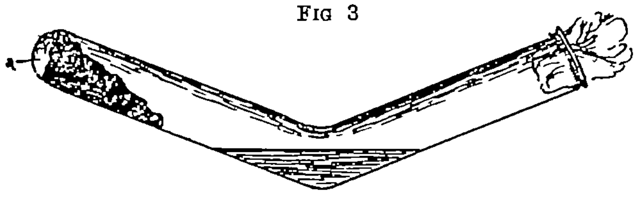
Hence when we wish to collect as much serum as possible we ought to collect our blood in warmed tubes and incubate it as soon as possible After an hour or two it may be kept at the room temperature if desired but the ice chest should be avoided until complete retraction has taken place I should add that this fact was first pointed out to me by Dr Cartwright Wood

I will conclude by giving two methods by which a very full crop of serum can be obtained in a very simple manner, and one which does away with any chance of contamination or the addition of foreign substances They are based on the power that a clot has of adhering with some tenacity to a paraffined surface

Description of Methods

1 Bend a test-tube (as long as possible) about the middle to an angle of 135° or thereabouts After sterilising it pour in a small amount of melted paraffin, heat it, and keep the tube upright until it is cold When set the paraffin will form a layer at the bottom of the tube , it is an advantage to let it run along the side of the tube away from which the upper limb is turned (that which is lower when the tube is placed on its side, as in Fig 3) A tube thus prepared will, of course, keep indefinitely To use it, fill with blood short of the angle and keep it upright until coagulation has taken place—of course in the incubator (Fig 2) Then put it down on its side, slightly tilted so that the serum may drain down into the angle With a tube of the ordinary test-tube diameter and containing 8–10 c c of blood retraction will usually be complete in two hours or less, and it will be seen that the clot has stuck to the paraffined surface of the tube, whilst it has retracted elsewhere, and has allowed the serum to collect in the angle of the tube (Fig 3)

FIG 3



Workers may like to compare this method with that described by Dr Gardner in THE LANCET of July 14th Beside the advantage that the tubes can be kept ready for use, I find it more efficient Thus in one experiment in which a sample of blood was divided between one of my tubes and one of Dr Gardner's, and the crop of serum examined after two hours' incubation, I got the following results —

In the paraffined tube Total volume of blood, 7 7 c c Volume of serum, 3 3 c c Amount, 42 9 per cent

In the agar tube Total volume of blood, 12 6 c c Amount of serum, 3 1 c c , or 23 8 per cent

The experiment was a little unfair in that the paraffined tube contained rather less blood so that a relatively larger crop might have been expected Retraction in the agar tube is, as Dr Gardner states, decidedly better than in ordinary tubes

FIG 4

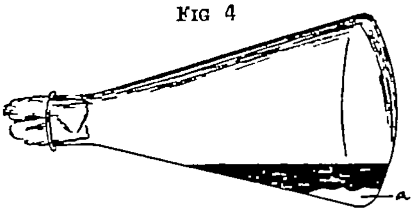


FIG 5

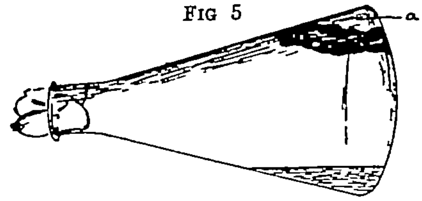

2 In case the angled tube is objected to, and only ordinary laboratory apparatus preferred, I have modified the method by paraffining the side of a flask The blood is allowed to clot in contact with this surface, the flask being kept on its side the paraffined surface should not be so large that the blood does not touch the glass or coagulation will be unduly delayed When this is complete, turn the flask round so that the blood is uppermost The serum will be very rapidly expressed and form a pool on the opposite side of the flask In one experiment the blood took one hour to clot and gave 42 8 per cent. in another half hour (Figs 4 and 5)

I have to thank Mr H T Rymer for his kindness in drawing me the illustrations which accompany this article

GASTRIC ATONY AND WAR NEURASTHENIA

BY J CAMPBELL McCLURE, M D GLASG ,
CAPTAIN C A M C PHYSICIAN TO OUT PATIENTS FRENCH HOSPITAL, AND TO RED CROSS CLINIC FOR PHYSICAL TREATMENT OF OFFICERS LONDON

I SHOULD like to begin this short paper by an extract from Cannon s article on the Nature of Gastric Peristalsis [1]

> ' Tonus as an essential factor of gastric peristalsis is first given by vagus impulses and later maintained by the stomach itself—for (1) severing the vagi before feeding results in inactivity (2) severing the vagi after digestion is started causes no change in gastric movements or in the rate of discharge Probably a psychic tonus is developed by the taking of food The method of maintaining the tonic state locally as digestion proceeds and of increasing it as the stomach empties is not yet determined It may be the result of a ' contraction remainder after each rhythmic pulsation
>
> The above results account for the functions of the vagi and the splanchnics They are nerves which increase or decrease the tonus of gastric musculature and thereby affect peristalsis The absence of stomach movements for example in states of exhaustion can be explained by the failure of vagus impulses and in emotional states by the presence of splanchnic impulses Both conditions result in absence of gastric tonus '

It seems to me that this physiological observation may throw some light on a condition which is at present a source of considerable trouble to those who are dealing with war neurasthenics

Description of Condition

I have seen in the past two years a large number of soldiers suffering from neurasthenia, either with or without a definite history of shell shock, who, in addition to the physical exhaustion and psychasthenia common in these cases, have suffered definitely from sensations referable to the abdomen, such as aching in the left hypochondrium, pain in the epigastrium, a sensation of constriction in the lower sternal region, and a general feeling of sinking referred not only to the epigastrium but perhaps to the whole abdomen Many of these show disordered cardiac action, particularly in the direction of intermittent tachycardia, extrasystoles, or persistent rapid action The systolic blood pressure is usually low, between 110 and 120 Many of them have suffered also from slight but definite pain in the right hypochondrium and right and left iliac regions They are for the most part listless suffer from loss of appetite, and complain of a feeling of distension after eating which persists for some hours, and indeed may not pass off before the time for the next meal Most of them are constipated, and some suffer from alternate constipation and diarrhœa

All these men have been subjected, apart from definite shell shock to experiences which are exhausting physically and mentally trying Vigilance, anxiety responsibility and lack of sleep, together with *exposure to noise* have all contributed to produce a condition of physical and mental exhaustion combined with severe emotional disturbance One has to remember in dealing with such patients at the present time that in the case of the bravest man the emotion of fear, or if we choose to call it so, of anxiety, is a contributing factor in the production of any condition of muscular and nervous weakness

The progress of such cases is in most instances unsatisfactory They improve after rest in hospital up to a point—that is to say, they get stronger, sleep better lose their fears and are able to take an interest in their surroundings and in the general topics of the day They may even be able to take up serious reading with interest But the abdominal symptoms remain although pain may disappear uneasiness may persist either in the epigastrium or in the right or left hypochondrium and under excitement or worry the feeling of sinking in the abdomen and the general muscular feebleness are apt to recur

In the vast majority of such cases, in my experience, auscultatory percussion of the stomach reveals the fact that the upper border of clear percussion is unusually high associated in many cases, but not invariably with some spreading to the left of tympanitic percussion An X ray examination after an opaque meal shows a high air bubble and a stomach slightly more capacious than normally and rather slow to empty There may or may not be an undue amount of ileo colic stasis

---

[1] Cannon The Nature of Gastric Peristalsis Am Journ of Physiology 1911-12 xxix p 264 &c.

Treatment

This condition of gastro-intestinal atony may persist for a long time and is irksome to the patient and physician alike It does not disappear even after a prolonged rest and careful dieting or, if it does so, is apt to recur as soon as the patient begins to get about It is not influenced very greatly by rigid dieting, indeed a patient seems to do better on an ordinary sensible, mixed fresh food diet, so long as the food given does not contain too much indigestible residue, than when he is confined to a diet that is fluid or semi fluid In fact, in most cases the patient has a very fair idea of what he can eat and what he ought to avoid, but, of course, alcohol and the excessive use of tobacco must be forbidden. In respect of this point there is one caution that must be insisted upon, and that is that in those cases where the abdominal discomfort and pain is practically constant patients are apt, unless encouraged to eat, to avoid food almost entirely, and it has to be explained to them that any kind of food would give them the same amount of discomfort, and that they must eat if strength is to be maintained This is a difficulty which presents itself in dealing with any kind of gastric neurasthenic

Cannon s paper throws some light on the causation of their condition and also indicates along what lines treatment should proceed The experiences of a man, and especially of an officer, during this war are such as to produce just that condition of exhaustion of vagus centres and emotional disturbance which tend to produce atony of the stomach either from failure of vagus impulses or from an excess of splanchnic impulses, with a resulting loss of gastric tone The difference between the atony produced by emotional states through the splanchnics and that produced by the failure of vagus impulses on account of exhaustion of centres may be of some clinical importance both as regards prognosis and treatment It is often of considerable difficulty to determine with which class of case one is confronted, and in the absence of any definite laboratory test there remains only the test of the clinical progress of the patient It is my practice to keep all such cases in bed for a while after they have come under my observation, although they may have been in hospital for a considerable time previously, and treat them by the use of such general sedatives as bromide and belladonna direct stimulants such as hydrastis, which Major Black has used with good effect in this connexion,[2] and by the manipulative methods and proper spacing of meals as described by Mitchell,[3] Wethered,[4] and McClure [5] In a number of cases both the neurasthenic and abdominal conditions clear up rapidly under this combination of treatment, and I am inclined to believe that in these cases the gastric fault is largely due to an undue increase of splanchnic impulses, combined, perhaps with local lesions of the gastro-intestinal mucous membrane, the result of hurried or improper feeding There may be in such cases a certain amount of vagus failure but not to any serious extent Such patients do well, and are speedily advanced to convalescence and successfully returned to duty

The Two Classes of Cases

The majority of cases, however, do not recover quickly The gastric condition improves and relapses and although after many weeks of careful manipulative treatment or even general massage electrical treatment, and encouragement on the part of all in contact with him, the patient may leave the hospital feeling fairly well or even quite well he tends to relapse at once if he undertakes work involving any great degree of muscular or physical strain.

These are the main differences between the two classes of neurasthenia associated with gastric atony which I have met with in soldiers. In the former class, who recover quickly and apparently completely after suitable treatment, I believe that the gastric atony is due to over influence of splanchnics By the use of suitable sedatives and stimulation of the vagus trunk by manipulative treatment over the abdominal areas first described by Mitchell [3] and confirmed by Wethered [4] and McClure,[5] the proper balance between the vagus and splanchnic impulses to the stomach is restored and the organ recovers its tone rapidly and completely In the latter class wh se convalescence is long and too often incomplete, it appears likely that the nervous fault which produces the gastric atony is failure of impulses due to exhaustion of the vagus centres This belief seems to be confirmed by the results of manipulative treatment in such cases It appears to be likely that the stimulation of the skin areas over the abdomen induces increased tonus and peristalsis of the stomach through the vagus trunk, and the comparative failure of this line of treatment to produce either a rapid improvement or permanent cure in this latter group is only natural if the atony be due to exhaustion of vagus centres

Cases Due to Vagus Failure

Such cases are difficult to handle from the start Their muscular feebleness, combined with abdominal discomfort, makes them apprehensive and depressed From the psychological point of view it is no use telling them to buck up and help themselves to get well A physician in charge can best encourage his patient by explaining from the outset that the illness is likely to be fairly long, improvement must be gradual, and perhaps a little slow, but that the ultimate outlook is good It is not wise to keep these cases too long in hospital, as they absorb with great ease the hospital atmosphere and develop habits of invalidism The best way of treating them is to have them rested sufficiently long and treated by all the special methods suitable for their condition, such as manipulative treatment of the abdomen suitable baths and douches, and various kinds of electrical treatment, including the static It is necessary to caution those who have such patients under their care that the manipulative treatment of the stomach by the excitation of the cutaneo gastric reflex, while forming in my opinion an essential part of their treatment, must not be carried on too long at one sitting, as one is apt to tire the patient too much, simple and slight as the manipulation may appear to be

After the first definite improvement has taken place and the patient is able to go about, it is usually better in such cases to send him away from hospital for a time, so that he may live quietly in the country and take slight exercise well within his powers After this period of rest the patient may be brought back again to hospital or may be treated as an out patient, either in the consulting room or a clinic while living in some place other than a hospital, that is, in his own home or some small convalescent hospital where the medical atmosphere is not too obtrusive, and yet where he is still under control

After a period of out-patient treatment of this kind the patient should again be sent to the country, and the necessity for recalling him as an out-patient depends upon his capacity for taking exercise and developing some hobby

In addition to the forms of treatment mentioned many cases of this kind respond well to certain organo-therapeutic preparations Certain polyglandular extracts, extracts prepared from the duodenal mucous membrane, pituitary extract, and small doses of thyroid combined with didymin, have all been found useful in suitable cases I have come to the conclusion that proper organo-therapy is an essential part in the treatment of cases of vagus failure, and materially helps in the prevention of relapses

It is well to point out that in a bad breakdown of this type it is useless to expect anything like a reasonable convalescence for many months, and during the whole period of treatment the patient should, as far as possible, be spared any unnecessary worry or excitement I have known a case that was progressing favourably so upset by unskilful handling at his medical board that a serious relapse was induced. In this particular instance a most enthusiastic young soldier was practically charged with malingering, and the mental effect of this was disastrous It is well for people to realise that even in war time and in the case of a soldier a man may be very ill without presenting any very gross lesion on physical examination and may, indeed, as far as fitness for service goes, be in as bad a condition as the man who has a stiff joint as the result of a bullet wound. It is true that a skilful malingerer may simulate with some success a neurasthenic state, but no one need make the mistake of classing as a malingerer a man who suffers from neurasthenia associated with gastric atony, whether due to the over influence of splanchnics or the failure of vagus impulses A little care in the examination of the abdomen in the recumbent position will reveal an upper border of stomach that is abnormally high, and perhaps some spreading of the gastric area of clear percussion to the left, while an X ray examination in the upright position will show a very high air bubble, and as often as not a definite degree of gastric stasis with some dropping of the stomach

[3] THE LANCET Jan 28th 1911

[4] Practitioner December 1911

[5] THE LANCET Sept 25th 1915

It is very wise in cases of this kind not to subject the patient too often to examination by a medical board It is quite sufficient to examine them every three or even six months to begin with and the time for such an examination, also, should be definitely fixed and the appointment kept by the examiners I have known cases have a relapse while waiting anxiously for ten days or a fortnight before hearing that their medical board has been fixed These may be small matters, but the treatment of neurasthenics is successful only by scrupulous attention to small matters, and the physician in charge needs every possible assistance from all those in any way connected with the case, whether in or out of hospital

Harley-street, W

DIATHERMY,

FOR THE TREATMENT OF CERTAIN LOCAL ABNORMALITIES OF THE SKIN

BY LULLUM WOOD BATHURST, M D LOND ,
PHYSICIAN IN CHARGE OF THE ELECTRO-THERAPEUTIC DEPARTMENT (OFFICERS SECTION) ROYAL FREE HOSPITAL.

THERE appears to be among the general public quite a widespread impression that certain affections of the skin, which may be grouped under the title of "blemishes," are such as the medical profession does not deign to treat or considers of so little importance (perhaps merely a question of vanity) that they would not be inclined to give the attention which, in the opinion of the patient, the particular condition deserves It is true, also, that a large number of practitioners are not aware of the advance in electro therapeutics which permits of these 'blemishes" being removed with an efficiency and accuracy which were not possible a few years ago Small wonder, therefore that many such sufferers are attracted by the flaunted advertisements of miraculous cures, whether by local applications, medicines, or at the hands of some unqualified practitioners

In diathermy we possess a means of dealing with, and in most cases of effectually curing, many conditions of the skin which till recently had been treated in various other ways, often with only partial success

The conditions referred to are such abnormalities as the different forms of moles and warts, corns, stellate veins, telangiectases, capillary nævi, port-wine marks, xanthelasma, acne, keloid, adenomata, freckles, &c

The treatment formerly employed in these cases has usually come under one of the following heads 1 Local applications of a caustic, such as silver nitrate acetic acid, nitric acid, sulphuric acid, trichloracetic acid, &c 2 The actual cautery 3 Ionisation with chlorine, magnesium, zinc, &c , by means of pads soaked in solution of the appropriate salts and applied to the surface 4 Simple electrolysis 5 Transfixion with a zinc or copper needle and the passage of the electric current, thereby again employing the caustic ions of zinc or copper 6 Freezing by means of carbonic acid snow

Some of the advantages which the method shortly to be described presents over these methods are (*a*) The rapidity with which the treatment can be carried out (*b*) The absence of inflammatory reaction (*c*) The accuracy and limitation which can be secured to definite areas whether large or small and however irregular (*d*) The depth to which destruction of tissue is to be carried out can be gauged and regulated (*e*) Scarring is much reduced in area and less noticeable. (*f*) The treatment is comparatively painless Even children frequently tolerate it without a murmur

The Mode of Treatment

The apparatus necessary consists of one of the various patterns of diathermy apparatus (several very efficient ones are now on the market made by English firms) and a high frequency couch with handles The patient is placed on the couch with his hands grasping the handles, and the electrodes from the diathermy apparatus are fastened to the metallic plate at the back of the couch and to the handles respectively The current is then turned on to give a reading of from 0 25 amp to 0 50 ampere By this means the patient becomes part of a charged condenser, of which the cushion of the couch is the dielectric and he and the metallic plate at the back of the couch are the two conducting surfaces If, then, a metallic instrument be approximated to his skin a discharge of electric current takes place from the skin to the instrument in the form of a spark. For the purpose under consideration a pointed silver probe (uninsulated) answers the purpose very well, but for the sake of adjustment to individual cases it is convenient to have several probes with fine and blunt pointing An ebonite rod may be held in the left hand to place against the patient as a means of support for the operating hand If this is not done unpleasant sparking may occur through inadvertently touching the patient

The instrument is then brought at right-angles to the skin so that the point is almost in contact with the surface to be attacked, when fine sparking is observed to take place This is allowed to occur for a variable time, measured by seconds, according to the depth and area to be treated, when a yellowish white, depressed surface remains Little or no surrounding inflammation occurs and no dressing is required The destroyed area crumbles away in the course of a few days, leaving in the case of small moles no perceptible scar, and when larger surfaces have been treated a slightly depressed whitish, soft scar

As an instance of the quickness with which this treatment can be carried out, I not long ago removed 17 moles on the face in less than ten minutes

The powerful mental effect which, in the case of women particularly, so often accompanies a comparatively slight facial disfigurement is alone a justification of the importance of dealing effectively with many of these abnormalities

THE RELATION OF THE CASE OF CEREBRO-SPINAL FEVER TO THE POSITIVE CONTACTS

BY P FILDES, M B , B C CAMB ,
ASSISTANT BACTERIOLOGIST TO THE LONDON HOSPITAL HONORARY STAFF SURGEON R N V R.
(*Working on Behalf of the Medical Research Committee*)
AND
S L BAKER, M R C S , L R C P LOND ,
TEMPORARY SURGEON R.N
(*From the Laboratory, R N Hospital, Haslar*)

ONE of the problems of practical importance in connexion with cerebro-spinal fever is the question whether the case has infected those of his contacts who are subsequently found to be positive, or whether the case has been infected by one of a collection of already positive contacts

There appear to be two fundamentally different views upon this subject According to the *first*, the case is essentially a carrier and is responsible for propagating the disease by spraying cocci from his throat The positive contacts have derived their infection from the case and may develop the disease According to the *second* view the case is not a carrier in the ordinary sense of the word, and is not specially responsible for propagating the disease The positive contacts, if any, have derived their infection from another carrier, and the case is infected by one or more of these contacts

The correct elucidation of this problem has a bearing upon cerebro-spinal fever administration in the Navy The first view would suggest that if, for instance a case is brought into a general ward before removal to an isolation hospital, not only the original messmates of the case should be swabbed, but also the patients in the ward, *to see if the case has infected anyone* On the other hand, the second view would not entail the swabbing of the ward, because the object in view is to *find the carrier who infected the case*

There appears to be no direct method by which this question may be settled, however excellent are the facilities for tracing infection The positive contacts are only discovered upon the occurrence of a case, and then it cannot be deduced which individual acquired the coccus first Indirectly however, important evidence is forthcoming According to the first view, the case must be a carrier before the onset of the disease Further if the case is a carrier it must be common for carriers to develop cerebro spinal fever

Our results obtained from a very large material indicate that neither of these consequences is correct

1 *The presence of meningococci in the throats of cases before the onset of the disease* —Owing to certain regulations which exist in the Navy it has been possible for us to examine the throats of a number of men who subsequently developed cerebro-spinal fever On the outbreak of symptoms these men were treated in Haslar Hospital and were then repeatedly examined by us In the following table the interval of time between the first swab and the onset of symptoms is indicated —

Case No	Date of swab before onset	Result	Date of onset.	Days interval
437	Dec 1st 1916	Neg	Feb 4th 1917	65
182	15th		Jan 3rd	19
705	22nd		March 7th	75
343	23rd		Jan. 13th	21
357	29th		22nd	24
206	31st		4th	4
344	31st		20th	20
414	Jan 8th 1917		31st	23
469	26th		Feb 8th	10
468	31st		8th	8
568	Feb 1st		19th	18
704	3rd		March 6th	31
536	10th		Feb 15th	5
567	11th		19th	8
565	11th		19th	8
868	15th		April 11th	70
633	18th		Feb 22nd	4
696	22nd		March 5th	11
790	25th		7th	10
737	25th		10th	13
809	27th		21st	22
687	March 2nd		4th	2
841	6th April 4th and 10th		April 18th	43 14 and 8
706	March 8th		March 12th	4
845	13th and 16th		April 2nd	20 and 17
1028	18th		May 27th	70

It will be observed that in every one of the 26 cases the swab taken before the onset was negative One of the cases was examined three times and another twice The swabs were taken at varying times before the onset, some of them very shortly before—namely, one 2 days and three 4 days

It would, therefore appear that cases of cerebro spinal fever are not carriers before the onset of symptoms, or, allowing for an experimental error which cannot be high, cases can seldom be carriers before the onset

2 *The occurrence of cerebro spinal fever among carriers* —It has been stated by Colonel M H Gordon 'that every case of cerebro spinal fever is an instance of a carrier developing the disease ' In the last section however, it will be seen that this statement requires modification In endeavouring to establish the occurrence of the disease among carriers it is necessary to confine the inquiry to men who have actually been proved to be carriers before the onset of the supposed disease Captain M Flack in his report upon the outbreak in London [1] refers to four such cases as occurring among his 185 carriers From the account given, however, it cannot be said to be certain that all of these men were instances of this phenomenon We have had a considerably larger number of carriers under observation—namely, 485, all were interned in one camp, and all were proved to be carriers of epidemic types of meningococci None of these men developed cerebro-spinal fever and therefore we may conclude that a carrier very rarely develops the disease

Since therefore both foundations for maintaining to the contrary are found to be wrong we conclude that the case of cerebro-spinal fever is not specially responsible for the spread of the disease and is infected by one of the positive contacts

We look upon the case as one of the rare individuals who cannot confine the meningococci to the naso-pharynx and merely "carry Our results also appear to indicate that in such a case the cocci pass very rapidly to the central nervous system after gaining access to the naso-pharynx

---

CARDIAC DIGITAL PERCUSSION

BY W GORDON, M D CAMB, F R C P LOND,
PHYSICIAN TO THE ROYAL DEVON AND EXETER HOSPITAL
AND
C E W BELL M R C S ENG, L R C P EDIN,
SURGEON TO THE ROYAL DEVON AND EXETER HOSPITAL.

[*Prefatory Note by* Dr GORDON —My colleague, Mr Bell, has been so good as to associate himself with me in this paper I cannot over emphasise the importance of his support Mr Bell is well known to be one of the finest violinists in the West of England, and the accuracy of his ear is unquestionable For my own ear I can make no such claim, but in the technique of digital percussion even an indifferent pianist possesses some advantage]

Consideration of Three Points

We desire to direct attention to the following three points (1) That the "superficial" as distinguished from the "deep" cardiac dullness is at present practically unimportant, (2) that the difference, generally described, between the results of "light" and "heavy" percussion in defining the cardiac dullness is, usually if not always, due to faulty methods of percussion, and (3) that the general failure to recognise the striking changes usually produced in the digital cardiac dullness by change of posture from erect to recumbent, is due to faulty methods of percussion, and is responsible for errors in diagnosis and prognosis which go far to interfere with the progress of cardiology

1 "*Superficial" and deep" cardiac dullness* —We know of no authority on cardiac physical signs who does not lay stress on the distinction between "superficial" and "deep" cardiac dullness But neither do we know of any who gives an adequate reason for doing so For at present no practical use is made of the ' superficial" dullness A little reflection will make that evident Some day some important use may be found for the "superficial" dullness, but at present it only serves to confuse the student, distracting his attention from the "deep" dullness which, with existing knowledge alone really matters We feel justified therefore, in what follows, in ignoring the unimportant "superficial" dullness and in speaking of the "deep" cardiac dullness simply as ' the cardiac dullness "

2 "*Light" and ' heavy" percussion* —It is commonly said that 'light" and 'heavy" percussion give constantly quite different results in delimiting the cardiac dullness Our experience is not in accordance with this On the contrary we find that, if a clear note be elicited, "light" and "heavy' percussion yield practically identical results Obviously either we or those who find differently from us must be defective in hearing or in methods of percussion As we are approaching the subject with a specially trained ear we do not admit any defect of hearing on our part With methods of percussion we shall deal immediately

3 *Posture and cardiac dullness* —The failure of the profession generally to recognise the change in the cardiac dullness, which is usually produced by change of posture from the erect to the recumbent, is remarkable But there can be no doubt of this failure For when the change so caused in the normal dullness was pointed out in 1905 at a meeting of the Royal Medical and Chirurgical Society, it was a new fact and had to be verified [1], in 1910 when attention was again drawn to it, and especially to the change in the rightward edge of the dullness, both in health and disease [2] the correctness of the observations was at once called in question, and at the present time cardiac cases are continually being recorded with no statement added of the posture in which percussional measurements are made

Text-book medical literature is silent on the subject Obviously, therefore, either our method of percussion or that in general use must be defective The question is "Which?" We naturally think that our own frequently repeated observations are correct yet, if they are unverifiable by others, the presumption would be strong that some fallacy underlay them They have however, been repeatedly so verified Further they have yielded useful results which appear undiscoverable by the methods in fashion Thus we have found almost constant differences in dullness in differing positions whose recognition enables us to watch week by week with no fear of fallacy the progress of cardiac cases under our treatment, where they are not present evident reasons have been found to explain their absence, and the remarkable diminution in the recumbent dullness in cases of cancer[3] has placed within our reach a new aid in diagnosis All these facts have been already sufficiently enlarged on and illustrated in former papers[4] We have therefore been emboldened to ask ourselves whether the methods in common use are superior to our own and to arrive at the very definite conclusion that they are not. In fact we believe that we are enunciating a very important truth in asserting that the methods of digital percussion now in general use are faulty and misleading

Comparison of Methods

But, in making this assertion, we have first to define exactly what we mean by digital percussion Of recent years, the modifications which, naturally enough, have arisen in percussional methods have rather tended to confuse the subject Obviously we are not dealing with results obtained with pleximeters, equally obviously not with so-called "auscultatory percussion." Nor with so called "palpatory percussion," which concerns itself, either wholly or in part, with the sense of differing resistance Our remarks relate solely to the production of sounds by the percussion of finger on finger, at present incomparably the most important form of percussion, because incomparably the commonest We would recall in passing the admitted fact that the results obtained by it in competent hands coincide remarkably with anatomical findings

There is nothing new in our method, which differs in no material particular from that which is theoretically approved in text-books It is this Moving the right hand loosely from the wrist-joint, we strike with its middle finger, bent, as in piano playing, to deliver the blow perpendicularly, upon the middle phalanx of the middle finger of the left hand, laid flat, evenly and rather lightly on the chest, parallel to the margin of the dullness to be defined The note thus obtained, whether loud or faint, according to the force used, is clear

When comparing the dullness in the erect with that in the recumbent position, in order to avoid possible errors of observation due to differing modes of application of the left hand to the chest, the left hand has been applied in both positions in the same way, with the fingers directed towards the abdomen

On the other hand the methods now in common use are by no means such as are theoretically approved in text-books Comparatively few persons percuss loosely from the wrist or use their fingers as we have described Two or three fingers are often used together to strike with they are not bent to strike perpendicularly to the chest wall and the impact is often more of a push than a blow The results are what might be expected The note is not clear and is sometimes scarcely even audible Such indistinct percussion sounds are quite incapable of defining dullness with precision Nor is this faultiness of method confined to the careless or to the second rate We have sometimes been filled with admiration, whilst listening to the percussion of better men than ourselves, at the acumen which could deduce anything from sounds so inadequate

And for this the reason seems to us not far to seek We venture to believe that the teaching of percussion is much below the high level otherwise maintained in medical education It would appear that percussion is thought too simple an affair for serious trouble to be taken with it But that is a most unfortunate mistake A good method of percussion —i e, one capable of producing a clear clearly audible note —does not come naturally to anyone *except a pianist*, and often great pains must be spent upon its acquisition Let us ask ourselves how often such pains are taken, or how often the need for them is insisted on Not commonly, we believe And so a most important means of clinical investigation is not commonly acquired

The history of percussion itself illustrates the difficulty the profession has always found with it Auenbrugger of Vienna, published his discovery of digital percussion in 1761 Yet little came of it for nearly half a century Then in 1808 Corvisart Napoleon I's physician, lighted on Auenbrugger s work and republished it in French with commentaries of his own Even then, according to Sahli,[5] it did not become the common property of physicians until the second half of the nineteenth century Something like a hundred years for the profession to acquaint itself with one of the most valuable clinical methods we possess!

In conclusion, we hope that the points we have raised will receive indulgent examination For if we are right—and there is at least a reasonable case for our contentions—diagnosis and prognosis in heart disease are now commonly rendered defective to a serious degree, and, if this be so it needs no tedious arguments to show that the progress of cardiology is thereby seriously interfered with

NERVOUS CRETINISM

BY F G CROOKSHANK, M D LOND, M R C P LOND,

PHYSICIAN TO OUT PATIENTS HAMPSTEAD GENERAL AND NORTH WEST LONDON HOSPITAL MEDICAL REGISTRAR, LONDON HOSPITAL, E.

Major R McCarrison I M S, in his lectures on goitre published several years ago,[1] declared that he has observed in Gilgit, and other places where cretinism is endemic, certain cases in which some *indicia* of cretinism are associated with nervous disorder of the nature of spastic diplegia He referred to these cases as "nervous cretinism," and described them as being often longheaded deaf mutes typically exhibiting a knock kneed spasticity of the legs with a stiff bobbing gait, and exaggerated knee jerks He stated also that the upper limbs are frequently spastic with the thumb tucked into the palm whilst the toes are often flexed on the sole The face was spoken of as "cretinoid," coarse nystagmus was mentioned as frequent, and variable squint as not uncommon

A picture was drawn, in fine, of a kind of idiocy, associated not with the physical characters of the orthodox cretin but with cerebral "*spastic diplegia of the types so* common at our out-patient departments and in our large institutions, and a definite relationship was established, on various grounds including that of therapeutic result, between these cases, and the commonly recognised cases of endemic dysthyreosis known as "cretins' At the same time the existence of *minor degrees of "nervous cretinism'* was clearly indicated

Demonstration of Cases in England

Little notice, unfortunately, was taken of this portion of Major McCarrison s lectures, but Dr (Major) Frederick Langmead, in 1913, demonstrated what he suggested to be a case of "nervous cretinism"[2] which was somewhat freely criticised in that the child did not appear to be a cretin in the ordinary sense of the word—one of the chief points made by McCarrison himself!

Such criticisms were, however, not substantial, and there is no doubt I think, that Dr Langmead did indeed show a case of dysthyreosis of the type called 'nervous cretinism" by Major McCarrison It at once called to my mind a private patient of my own a *little girl*, whose mother suffered from a mild degree of exophthalmic goitre, and who was brought to me because, to use the mother s own words "she always stood on her toes and pointed them in a funny way" There was, indeed, a tonic and persistent spasm of the calf muscles and the child walked badly She was cutting her last milk teeth and I thought she looked hypothyroidal I ordered her some thyroid gland substance for that reason and, on seeing her again some weeks later found that the gait was much improved and that the spasm had disappeared

At the time that Dr Langmead showed his case I was attached to the Belgrave Hospital and was able, in the course of a few months, to find several cases (corresponding to McCarrison s description of the milder types) which improved on thyroid feeding One of *these* was shown at a meeting of the Section for the Study of Disease in Children of the Royal Society of Medicine[3] My predecessor, Dr Hildred Carlill had seen the child some months earlier, before, indeed, the onset of the nervous symptoms and had marked the case sheet "? hypothyroidal " When I saw her there were spasm and weakness of the legs, and the "cretinoid" manifestations were as slight as they usually are in these cases But the spasm and diplegia disappeared completely under thyroid feeding and the child began again to talk freely She had latterly been relatively mute

I therefore express the opinion that, just as McCarrison has established the existence in places where cretinism is endemic of a spastic diplegia of varying degree, relieved, at any rate, when not of long standing, by thyroid treatment, so also in England are sporadic cases of similar nature to be met with *if looked for* In nearly every case of this nature that I have seen there has been definite evidence of dysthyreosis in the mother or in one or more other children of the same family

A Form of Thyroiditis in Brazil

Reference must now be made to the work of Chagas who is the discoverer, in Brazil of a peculiar "epi endemic" variety of thyroiditis associated with a trypanosome infection, and who insists that a proportion of the individuals attacked by this trypanosome (*T cruzi*) and developing the specific thyroiditis come to suffer from a kind of ' Little's disease" or ' cerebral diplegia," whereof the signs and symptoms vary from slight spasticity, with increase of knee jerks and tottering gait, to absolute idiocy and gross spastic diplegia.[4]

I do not know that Chagas has treated any of his cases with preparations of thyroid gland, and I gather that he is inclined to attribute the amentia and spastic palsy to cerebral changes wrought by the trypanosome rather than to any consequence of the thyroiditis itself, but the fact remains that he, independently of McCarrison, has established the clinical co-existence of dysthyreosis and spastic diplegia

And moreover, one must recall that which has been written or is known concerning the relation between the thyroid the parathyroids, and tetany making particular reference to the valuable paper by Paton and Findlay and to the letter by Dr Forsyth in response thereto, that have recently appeared in the *British Medical Journal* [5] [6]

Bearing in mind, too the association of lenticular degeneration with a form of hepatic disease, it is foolish to assert as I have heard it asserted on *a priori* grounds, that the cerebral changes of Chagas's long standing cases can have *no* relation to thyroidal or parathyroidal insufficiency, and equally unwise hastily to discredit the suggestion that there is a definite spastic diplegia to be met with in England associated with dysthyreosis and relieved by thyroid feeding

Later Observations Description of Condition

Since returning from France early this year, after an absence of more than two years that has broken all links with the 10 or 12 cases I had under observation in 1914 I have come across ten or a dozen more of which eight are at present under treatment and definitely and steadily improving and I venture therefore provisionally to summarise some present conclusions in dogmatic form —

The nervous symptoms that are associated in the child with atypical athyreosis are *to be* recognised as forming degrees of the state described by McCarrison as "nervous cretinism "

Nervous cretinism " occurs in England possibly endemically but certainly, if not sporadically," at any rate without obvious endemic associations

In almost every case that I have seen which appears to deserve the appellation of nervous cretinism," there has been evidence of dysthyreosis in the mother or other members of her family

The earliest manifestations of *mild* " nervous cretinism " are generally regarded as ' tetany, and occur towards the end of the second year of life (or a little later) when the child has well learnt to walk and talk

There is sometimes seen about this time a pale puffiness or fatness that represents the myxœdematous phase of dysthyreosis, it is usually only transient and there is some reason also to think that the nervous symptoms themselves are not necessarily progressive even when untreated, but may tend towards regression

Following the ' tetany '—or stage of remittent spasm—there may ensue a stage of weakness, with tottering gait and a more persistent spasm that passes into a condition not to be distinguished from "congenital spastic diplegia" or ' Little s disease ' of moderate degree

In the more severe cases mental defect is obvious almost from very earl days, and the early appearance of spasm with nystagmus leads to the confident diagnosis of congenital spastic diplegia

The relation of these cases to the group of "mild" nervous cretinism is shown by the familial dysthyreosis and by the at least partial response to thyroid medication sometimes by familial incidence The mild cases whose nervous symptoms first attract notice towards the end of the second year or thereabouts are not "cretins" in the ordinary sense of the term and frequently, in the beginning, docile and pleasing children They are sometimes, however, broad-headed and their "hypothyroidal" quality may be manifest in the arrangement of their forehead hair and eyebrows, and in the waxen puffiness of their skin

Whilst there is no reason at all to suppose that more than a certain proportion of cases of "congenital spastic diplegia" are really cases of " nervous cretinism " it should be remembered that (*a*) The results of the post-mortem investigations on these cases are oddly puzzling, anomalous, and inconsistent,[7] (*b*) in many cases of congenital spastic diplegia there is *no* history of prolonged, difficult, or instrumental labour, (*c*) oftentimes the mother definitely asserts that the child had "nothing wrong till two or later," and once walked well, (*d*) *familial* congenital spastic diplegia is described

No claim is made for the " cure " of established cases of "Little's disease" or congenital spastic palsy by thyroid tablets, but certain cases of young children, diagnosed by specially competent physicians as "congenital spastic diplegia with amentia," have definitely responded to treatment by thyroid, whilst *cases of "tetany" 'spasm,"* "weak legs," and so forth, recognised as corresponding to McCarrison's milder cases of nervous cretinism, have become quite cured whilst taking the same substance The effects, on similar cases, of parathyroid medication, I have not yet noted

A NOTE ON THE OCCURRENCE OF "BLUE PUS" IN SEPTIC WOUNDS

BY THOMAS H KELLOCK, M C CAMB, F R C S ENG,
CAPTAIN R.A M C (T)
AND
C RHODES HARRISON, M B, B S LOND,
CAPTAIN R A.M C (T)

THE appearance of "blue pus" in an open wound has long been recognised as a complication that may occur during the healing process and has generally been regarded as an ill omen and dealt with by the application of antiseptics, such as carbolic acid, with a view to its destruction, the results of this were generally quite successful, the blue colour and peculiar odour disappearing almost at once from the wound

In the many septic wounds with which we have had to deal recently it has struck us as peculiar in what a relatively large number of them the *Bacillus pyocyaneus* has appeared, it makes its appearance suddenly, in wounds both recent and old generally in one that has rather a large open surface pays but a short visit and vanishes as rapidly as it appears

Sometimes in opening the dressing of a wound which has apparently been running a normal course the characteristic odour is at once noticeable and one finds the wound, dressings and surrounding skin all covered with blue pus, the same dressing may be continued and in one, two, or three days all blue colour and odour may have disappeared and the wound apparently returned to its former condition Meanwhile the patient s general condition shows no change, the temperature is not altered, pain is neither more nor less, and in spite of the great disturbance that must have occurred among the microbic inhabitants of the wound owing to the extraordinarily rapid increase of *B pyocyaneus* the short visitation would seem to have brought about no change. It has, however, been our experience that wounds in which this occurs almost invariably do well afterwards , there may be no change for a day or two, but then an improvement takes place, the granulating surfaces become more healthy and vigorous, and healing follows quickly Why this should be is not very apparent, it may be that the very rapid growth of *B pyocyaneus* merely ousts or actually destroys the septic organisms that were present in the wound, or it may be that the bacillus is present from the beginning, and only increases with such vigour when the other organisms are weakening and have lost some of their vitality, so that the wound is already beginning to mend, and thus the spread of *B pyocyaneus* may have no share in bringing about an improvement , in the latter case one would have expected the growth of *B pyocyaneus* to continue instead of disappearing again rapidly as it generally does

It has thus come about that we have learnt to regard the appearance of blue pus in a septic wound as a favourable sign rather than the contrary, fully expecting that in due course improvement will come, and this has been so sure that a trial has been made to see what good would come of infecting sluggish or unhealthy-looking wounds with *Bacillus pyocyaneus* It proved to be rather difficult to get the infection to take , at first the wounds were merely touched with an emulsion of living organisms, and subsequently other more vigorous methods were employed, such as packing a wound with infected gauze, scratching the surface of the wound before infecting it and inserting on to a wound a living culture with the medium The results were variable , in many absolutely nothing occurred, but in some infection took place, and in these a marked subsequent improvement occurred in the condition of the wounds , on no occasion did any harm come to the wound or to the patient. Here, again, the question will naturally arise, Did the infection destroy or oust other organisms and so do good, or was it that only in those wounds that were on the point of improving naturally could infection be obtained ?

An interesting point noticed lately has been that the antiseptic flavine appears to have no effect on the *Bacillus pyocyaneus*, at any rate, in open wounds where septic organisms are also present the two seem quite compatible, to the great advantage of the wound.

From a bacteriological point of view this clinical observation is of interest, for the antagonism of *Bacillus pyocyaneus* to certain other bacteria has been shown by its power to impede the growth of the bacillus of anthrax in cultures and by the injection into an animal susceptible to anthrax of a mixture of the bacilli of blue pus and of anthrax, the latter disease then failing to develop Porcelain filtered cultures of *B pyocyaneus* are said to have similar properties Kitasato found that *B pyocyaneus* prevented the development of the vibrio of Asiatic cholera, and Rumpf claimed similar antagonism to *Bacillus typhosus*, but experiments designed to repeat the latter's observation show that the subject appears to be rendered more than usually susceptible to the action of enteric and of colon bacillus The ferment pyocyanase has been used for the removal of diphtheritic membrane and in the treatment of nasal catarrhs

Bacillus pyocyaneus shows considerable morphological variation and its chromogenic powers seem equally inconstant For example, from one of the wounds described above cultures infected on the first day of the sudden appearance of blue pus in the dressings showed *B pyocyaneus*, which produced abundant brilliant pigment, and by the rapidity of its growth rendered isolation of accompanying organisms difficult, while on the next day the wound and dressings without alteration in treatment presented neither the characteristic colour nor odour, and cultures on the same media showed *B pyocyaneus* in markedly reduced numbers growing feebly, and only after three days producing pigment even that being of the brownish variety, the bluish colour being absent throughout

Although usually harmless and sometimes apparently beneficial to a wound *B pyocyaneus* must always be regarded as at least a possible source of danger, as it can (though rarely) be recovered from the blood stream in certain terminal conditions, and has been described as the primary cause of a few cases of otitis and of enteritis

Experiments *in vitro* suggest that *B pyocyaneus* has little, if any power to impede the growth of *Streptococcus pyogenes* and *Staphylococcus aureus*, though possibly its products in the complex media presented by a wound may be of a different and deterrent nature

A CASE OF STRANGULATED FEMORAL HERNIA

BY THOMAS E COULSON, M D EDIN , F R C S EDIN ,
SURGEON TO THE MERTHYR GUEST HOSPITAL TEMPLECOMBE, AND TO THE WINCANTON AND GILLINGHAM V A.D HOSPITALS

THE following case of strangulated femoral hernia presents some unusual features

Mrs A., a strong, healthy looking woman, aged 50, whose only previous illness was perimastoid suppuration four years ago, gave a history of her present illness as follows During the last five or six months she had been suffering from occasional severe attacks of pain in the right iliac region The pain was so severe that it doubled her up," and if it came on when she was out for a walk it was with difficulty she reached home It usually made her sick, kept her in bed for a day or so, and then passed off, leaving her little the worse except for a bad taste in the mouth and a distaste for food for some days She was constipated, as a rule, both before and after an attack She had never noticed any swelling in the groin during any of this time

On June 1st, 1916, an exceptionally severe attack developed, but passed off as usual next day On June 12th, 1916, she went to bed as usual, but was wakened in the night by a severe pain in the right groin and was sick The pain continued to increase and spread over the whole abdomen It was still present next morning and was getting worse, being now especially severe round and above the umbilicus. She was sick again about midday (June 13th) and sent for me

When I saw the patient about 2 P M she was in bed had an anxious drawn expression, and had just vomited about a quarter of a pint of green stomach contents She complained of pain in the abdomen, coming on in paroxysms, especially in the right groin and just above the umbilicus The bowels had been opened that morning The temperature was 97° F and pulse 68 per minute The tongue was furred and inclined to be dry down the centre The abdomen was slightly distended and tympanitic, but was flaccid on palpation There was no special area of tenderness, but in the right groin was a firm, hard lump about the size of a Tangerine orange, dull on percussion, and with no impulse on coughing I diagnosed a strangulated femoral hernia and advised immediate operation for its relief She was accordingly admitted to the Merthyr Guest Hospital, Templecombe, and I operated at 3 P M that afternoon

Operation —After the usual shaving and painting the skin with chloroformum iodi an incision was made vertically and to the inner side of the lump about three inches long The hernial sac was thin and, on being opened, was found to contain, besides about one ounce of clear fluid, the cæcum and appendix The cæcum was nearly black in colour but shiny in appearance The appendix was swollen to twice its normal size, was black in colour and dull and lustreless in appearance There were also some tough adhesions between the base of the appendix and the peritoneum forming the neck of the sac There was no doubt in my mind that the appendix would not recover if returned to the abdomen , I therefore decided to remove it I first of all cut the adhesions between two ligatures, and, after tying the meso-appendix, removed the appendix and invaginated the stump in the cæcum by means of a purse string suture I then made two small incisions in Gimbernat's ligament, returned the cæcum to the abdomen ligatured the sac as high up as possible, and cut it off below the ligature Making no attempt at a radical cure, as the condition of the patient would not admit of this, I sutured the skin with salmon gut and returned the patient to bed

The wound healed by first intention, recovery was uninterrupted, and she has been free from all pain in the abdomen since the operation, which was performed a year ago

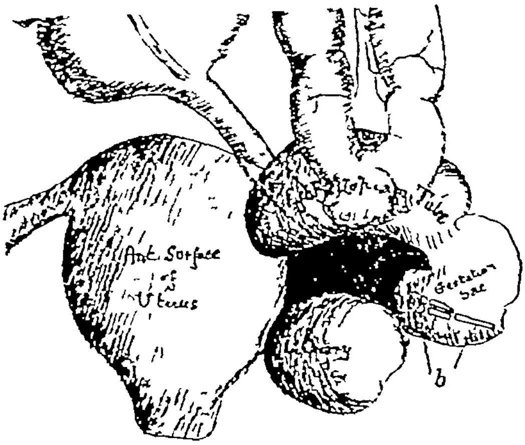
The interest of this case lies in the fact that the patient had before strangulation probably suffered from, at least three attacks of appendicitis of a mild nature but sufficiently severe to cause the formation of adhesions between the appendix and parietal peritoneum Another point of interest and importance is the fact that when the cæcum and appendix became strangulated in the hernia it was the appendix which suffered the more severely, evidenced by the fact that the appendix was dull and lustreless whilst the cæcum was shiny in appearance, this is possibly accounted for by the fact that the appendicular artery anastomoses with the vessels in the cæcum to a very limited extent,[1] so that in the event of it becoming obstructed, gangrene of the appendix is very prone to supervene with great rapidity

CASE OF EXTRA UTERINE GESTATION

By Evelyn A Constable, M B, B S Durh,

SURGICAL REGISTRAR, LONDON TEMPERANCE HOSPITAL.

Patient aged 31 was admitted to the London Temperance Hospital on Oct 10th, 1916, under the care of Dr Kevin Byrne, she had had abdominal pain for 12 months She was married in August, 1914 Confined on Nov 4th, 1915, of her first child at seven months (died in 15 hours) Six weeks later had her first monthly period, which was a heavy one and lasted one week. One month after this there was a very scanty loss every few days up to February, 1916, when a ' piece of shaggy flesh was passed (no blood with it) Then *total cessation* of menses until August after which periods became regular and normal in amount Patient had had abdominal pain since her confinement, but in February last she had "labour like pains," and considered herself pregnant Sent into an infirmary, where she remained from March to July Here she was curetted "for a miscarriage" The pains continued, and patient felt weak



b Fœtal bones

On admission to the London Temperance Hospital on Oct 10th a large swelling was in right side of pelvis and pouch of Douglas No vaginal discharge Uterus slightly larger than normal and pushed over to the left Nov 8th Note by Dr Byrne "The swelling on right side is smaller but still tender There is a swelling not previously observed, in corresponding region to left of uterus She has complained of rather more pain in lower abdomen and extending from right side to left" Nov 12th Menstruating Nov 16th Pain in lower abdomen especially right side much worse to-day Pain on superficial palpation, relieved on *deep* palpation No rigidity Nov 24th Operation by Mr J McClure

On opening abdomen the omentum vermiform appendix, and a loop of ileum were found adherent to the fundus of the uterus on the left side On freeing these (in doing which a small part of serous coat of gut was torn and had to be stitched up) a hard mass was found at the left tubo-uterine junction This turned out to be the left greatly dilated tube and ovary on the surface of which were some fœtal bones (as in figure *b*)—viz, a femur, tibia and fibula also metatarsals of both feet Close to the former and parallel to them were some nodules thought to be the spine with cranium at lower pole Parts removed were both Fallopian tubes, left ovary, gestation sac and vermiform appendix Patient made an uninterrupted recovery

I am indebted to Dr Byrne and Mr McClure for permission to report this case.

[1] A Treatise on Applied Anatomy by E. H Taylor p 455

St Thomas's Hospital Medical School — R H O B Robinson King's College Cambridge, has been awarded the University Scholarship of £50

Reviews and Notices of Books.

1. *The Causes of Tuberculosis* By Louis Cobbett, M D Camb, F R C S Eng, University Lecturer in Pathology, Cambridge Cambridge The University Press 1917 Pp 707 Price 21*s* net
2. *Clinical Tuberculosis* By Francis Marion Pottenger, A M, M D, LL D With a chapter on Laboratory Methods by Joseph Elbert Pottenger, A B, M D In two volumes London and Glasgow Henry Kimpton 1917 Pp 1416

1. This book on the Causes of Tuberculosis is primarily a digest of the work of the late Royal Commission on Tuberculosis, of the reported activities of the Local Government Board, of the Health Department of the City of New York, and of the Imperial Board of Health of Berlin It is also a good deal more, for the author, who has personally contributed much spade work to researches on tuberculosis, has gone considerably further afield in collecting valuable material He has also brought out his facts so skilfully that the validity of most of his conclusions will be questioned by few His is the ambitious object of providing a book at once for the medical profession and the lay public Undoubtedly it will prove useful to both and as a basis for lectures both to students and the public it should be invaluable The earlier chapters deal with the incidence of tuberculosis and the wonderful decline in the mortality from this cause during the last half century On the basis of the calculation that ' the ratio of deaths to population has fallen by more than 50 per cent " in this period, the author anticipates that ' tuberculosis will have become a rare disease before the end of the century " One of his most interesting conclusions is that in the case of both human and bovine tuberculosis " in the main it is the large doses of bacilli which are dangerous, and that small ones are often harmless or even beneficial by increasing resistance " His recommendations for combating both these forms of tuberculosis reflect this view The author is in favour of segregation, but he thinks that compulsion with this object must except in very exceptional cases, be renounced He is as a rule, so careful to weigh available evidence before attempting to formulate his conclusions that it is surprising to find him digressing from his main thesis to pass judgment on the achievements of sanatoriums without adequately reviewing the arguments for and against them They "take," he says, ' away with one hand what they give with the other " This attitude is surprising in a "segregationalist," as the provision of ample sanatorium accommodation automatically helps to solve the problem of segregation in the least objectionable manner To recommend segregation without a full discussion of all it implies is dangerous in a book partly intended for non medical readers The book, as an exposition of present-day knowledge of the causes of tuberculosis merits unreserved praise

2 Progress in our knowledge of tuberculosis is, along certain lines, so rapid that the sight of these bulky volumes at once suggests the mournful reflection that in a few years they may be out of date But on closer scrutiny these regrets prove superfluous, for this work is not just a compilation of others' researches brought up to date It represents rather the experience and thoughts of one man—the author His is a record of observations made during 20 years of clinical study conducted mainly at the Pottenger Sanatorium, California, and the reader will be struck by the originality of thought and the consistency of effort directed along certain specialised lines And yet the author shows a catholic knowledge of other aspects of his subject In the chapter on modes of infection the author says he has not had a single case of direct infection of employees and attendants in sanatoriums brought to his attention He sees in "massive" infection of children the chief danger which if avoided, would greatly limit active tuberculosis in the adult Further, he believes that recognition of the significance of early lymphatic tuberculosis would supply "the key to the tuberculous problem" He notes that tuberculin in childhood may often be the determining factor for good between the years 5 to 10 or 12. In a later chapter he says of tuberculin that after 20 years experience, he

believes that, properly administered, it "will add at least a minimum of 20 per cent to the chances of healing" But he is evidently no blind tuberculin fanatic, and he insists on its uselessness except in the hands of the expert prepared to individualise and to avoid all routine or haphazard methods A distinctive feature of the chapters on diagnosis is the almost meticulous study of symptoms, of which, even in the early stages, about 30 are described By careful analysis these symptoms are placed in three groups according to their etiology, which may be toxæmic, reflex, or local (the tuberculous process *per se*) Nervous instability belongs, for example, to the first group, cough to the second, and hæmoptysis to the third The author then tries to show how toxæmia can produce nervous instability and reflex action produce cough His main clue to these problems is sought in the nervous system, and he is indefatigable in following up the paths of reflex action As he says —

> In tuberculosis we must conceive of a condition in which both the vagus and the sympathetic systems are simultaneously stimulated, but one in which either one or the other usually yields with a resultant disturbed equilibrium

This, for example, is how he analyses the rapid pulse of tuberculosis (p 231) —

> It has long been said that a persistently rapid pulse in tuberculosis means a bad prognosis While this is not invariably true, there is some ground for it, because it means that the patient's sympathetic tonus is in the ascendancy It would be more rational to state that those patients who are distinctly of the sympathetic tonus type, or those people who have a decreased vagus tonus, which means practically the same thing, are not as able to withstand the disease as those who have increased vagus tonus

The author attaches great importance to the mental factor in tuberculosis, and he sees in the possession of magnetism, "Geist," personality by the physician an almost essential qualification Thus (p 651) —

> I would rather have a patient treated in a room, if I could give him the benefit of hydrotherapy and psychotherapy, with good food, than treat him in the open air with hydrotherapy and psychotherapy omitted

We have dwelt rather on the unusual than on the more commonplace features of this book, so let us add that it also represents broadly speaking, the views of the ablest pathologists and physicians of the day on the various aspects of tuberculosis The author has a trick of iteration The points he would emphasise and establish as pivots about which lesser factors revolve recur again and again They constitute refrains running throughout his work It would be easy enough for him greatly to condense what he has to say, but it would be at the loss of a fluent easy rhythm which conveys a vast store of knowledge The book offers no points of comparison with the average text-book and forms a comprehensive survey of its subject

---

1 *Les Psychonévroses de Guerre* By G ROUSSY, Professeur agrégé à la Faculté de Médecine de Paris, and JEAN LHERMITTE, Ancien Chef de Laboratoire à la Faculté de Médecine de Paris With 13 plates Paris Masson et Cie 1917 Pp 187 Price 4 francs

2 *Hystérie Pithiatisme et Troubles Nerveux d'Ordre Réflexe* By J BABINSKI, Membre de l'Académie de Médecine, and J FROMENT, Professeur agrégé Médecin des Hôpitaux de Lyon. With 37 figures and 8 plates 1917 Pp 267 Same publishers and price

1 THIS useful little volume is one of the latest additions to the series of war monographs published by the well known house of Masson The authors include under the term psychoneurosis every variety of functional disturbance from the simplest to the most complex, from those whose expression is almost entirely physical to those where psychical symptoms predominate Thus they comprise in their précis impairment of gait, involuntary movements of all sorts, sensory phenomena, disturbances of the special senses visceral troubles anxiety hysteria and the various mental symptoms of head injuries shell shock cases, and the other pathological states with which the war has made us familiar A chapter is devoted to commotio cerebralis The etiology of these different neuropathic and psychopathic conditions is outlined in some detail, and several sections are taken up with an attempt to guide the reader to a clear understanding of the part played by "simulation exaggeration" and 'simulation prolongation" The chapters on treatment are particularly good The rôle of the physician, and of the patient, the environment, and the exact procedures desirable receive full consideration The authors believe in reasoned and persuasive psychotherapy after the manner of Dejerine, Dubois, and Babinski They hold that suggestion under hypnotism should be abandoned altogether In their hands the methods here specified have been successful in from 98 to 99 per cent of cases

2 In view of the therapeutic importance of clearly distinguishing hysterical from other functional disorders of the central nervous system arising in the course of warfare a practical knowledge of their differential diagnosis is essential We do not know any modern volume in which the reader will find these difficult subjects so lucidly explained as in this not merely because one of the best working hypotheses of hysteria is associated with the name of M Babinski, but also because of the learned way in which the peculiarities of the condition known as reflex paralysis, often confused with hysteria, are here presented for consideration Reflex paralysis is a subject to which much attention has been given, yet in England the profession as a whole can scarcely be said to be familiar with it, since, however, it appears to occupy a place intermediate between the organic and the functional, its importance is considerable No doubt in this excellent little book the authors are more concerned with an exposition of their own views than with an examination of the views of others but its obvious merits should commend it to all who are in search of a compendium of information on war hysteria and allied conditions where questions of diagnosis, prognosis, and treatment are handled at some length There is, at the same time, more in the book than its appeal to the physician on the ground of practical usefulness, its appendices contain observations of much scientific interest for the neurologist, and there is a bibliography of some 250 references There are illustrative photographs and diagrams

Microbiology A Text book of Micro-organisms General and Applied By Various Contributors Edited by CHARLES E MARSHALL Professor of Microbiology and Director of Graduate School, Massachusetts Agricultural College Second edition revised and enlarged With 186 illustrations London J and A Churchill Pp 900 Price 12*s* 6*d* net

IN a review of the first edition of this book in THE LANCET of April 27th, 1912 the special features which distinguished the work were noted at some length It differed from the ordinary text-book in that it was a collection of short monographs by specialists and not the product of a single author There was, however, less overlapping and greater uniformity of treatment than might have been anticipated Further, the book was not apparently directed to the needs of any special group of readers, but furnished part of a general liberal education Its descriptive title was "Microbiology for Agricultural and Domestic Science Students," and "domestic science" was interpreted so as to include the diseases of men and animals plant diseases, sanitation, and, in fact any subject in which micro-organisms played a part The articles were not, however, of a popular character, but were a series of able, if necessarily limited monographs All laboratory methods were eliminated The qualifying expressions of the original title have now been dropped, and the book is described as an elementary technical treatise on the subjects included under the term microbiology, but there is no essential change in this second edition either in method or scope There has been a general revision of the work, and certain additions have been made which have increased the size of the book by some 300 pages while the illustrations are also more numerous The cytology of micro-organisms has become more defined in recent years and has received additional attention in the present edition at the hands of Dr Guilliermond professor of botany at Lyons A chapter has also been added on intestinal microbiology The space devoted to the microbial diseases of insects has been increased and especial attention is paid to those diseases which are of economic importance such as that caused by *B acridiorum* in locusts and those which affect bees

The book certainly gives a good general view of a very wide field of knowledge The size of the book still remains moderate and no fault can be found with the type and general appearance

Cerebellar Abscess, its Etiology, Pathology Diagnosis and Treatment, including Anatomy and Physiology of the Cerebellum By ISIDORE FRIESNER, M.D , Adjunct Professor of Otology and Assistant Aural Surgeon Manhattan Eye, Ear, and Throat Hospital New York, &c. and ALFRED BRAUN M D F A.C S Assistant Aural Surgeon, Manhattan Eye, Ear, and Throat Hospital New York, &c With 10 full page plates and 16 illustrations in text. London William Heinemann 1917 Pp 186 Price 12*s* 6*d* net.

THE authors have compiled a useful monograph on cerebellar abscess in all its bearings The sections on the anatomy and physiology of the cerebellum contain a résumé of the most recent work on the subject, of German origin be it remarked for while Lewandowsky Rothmann and Bárány are quoted from freely there is little apparent appreciation of the investigations of Horsley and R H Clarke and the valuable researches of André Thomas and Durupt on cerebellar localisation are ignored Further in the sections on symptomatology Bárány s tests are described in full, but there is no reference to the methods of Babinski, which are in some ways preferable It is curious too that while investigations associated with the names of German workers are usually quoted from the original sources methods of examination for which we are entirely indebted to the French and English schools of neurology are freely described without any acknowledgment of their origin The apparently one-sided nature of the writers' knowledge of cerebellar research is regrettable

From the clinical standpoint the common cerebellar symptoms are on the whole fairly presented to the reader though we notice a differentiation is drawn between the character' and the "behaviour" of nystagmus which is far from clear Further we are of the opinion that a greater acquaintance with cerebellar disease other than abscess might have led the authors to modify certain of their statements Tremor is mentioned but its localising significance is not stated, deviation of the head in certain cases is referred to, but not described in the specific way in which it usually occurs Cerebellar gait is not noted except in the briefest fashion, dysmetria asynergy, and adiadokokinesis are described separately without any hint of their interrelation The chapters on the prognosis and treatment of cerebellar abscess are, on the other hand, more complete and satisfactory

The Treatment of Tabetic Ataxia by Means of Systematic Exercise By Dr H S FRENKEL, Medical Superintendent of the Sanatorium Freihof in Heiden (Switzerland) Second revised and enlarged English edition by L. FREYBERGER, J P M D Vienna, M R.C P Lond Barrister at-Law of the Middle Temple &c. With 129 illustrations London William Heinemann 1917. Pp 209 Price 12*s* 6*d* net

Dr Frenkel s exercises for the treatment of the ataxia of tabes dorsalis have become justly famous and their abiding value in the tackling of a troublesome symptom has been demonstrated over and over again in the experience of physicians of all countries Their rationale can be readily grasped when we remember the words of Hughlings Jackson that when the dorsal columns of the cord are sclerosed the tabetic walks badly 'with what of his cord is left." Hence the importance of endeavouring to educate rather than to re-educate the muscle groups by a new combination of the eye and what remains of the cutaneous and deep sensory apparatus In this new edition there is full appreciation of the fact that the cause which keeps up the sclerosing process in the central nervous system must be obviated as far as possible by specific treatment and in the last chapter modern methods are described with some detail. It is not the purpose of the book however to go into this question completely But given a tabetic in an early stage or for that matter in a chronic stage his ataxia other things being equal will certainly be influenced favourably by patient treatment along the lines here described with ingenious care We have said that Frenkel s exercises are familiar to the physician, he should become a possessor of this handbook to realise how much the method can effect and how applicable it is to all forms of impaired control over the muscular system

JOURNALS

Military Surgeon (Washington, D C, U S A.)—The September number of this journal contains several articles of value on war surgery Dr E B Downer Red Cross surgeon in Serbia and director of a private mission to Russia, reports excellent results from bone-grafting in the treatment of ununited fractures The surgeon who takes up this branch should be first a skilled mechanic and next requires motor-driven tools Dr Downer declares he himself has the only motor driven outfit in Russia Bone splints lead to bone formation but steel plates prevent it The author's observations on surgical methods in each of the successive years of the war are judicious and should be read —Lieutenant-Colonel W L Keller, Medical Corps U S Army, sends a valuable paper on Surgical Work in a United States Army Hospital Amongst other things he describes a novel and successful treatment for bubo and for phagedænic ulcer The Report of the Mesopotamia Commission is reviewed It is regretted that the Commission included no medical member and it is noted that under those circumstances it was unlikely the medical department would escape censure It is observed that the preservation of the health of an army, and the efficient removal of its wounded have so much influence on the success or failure of every military undertaking that 'so long as the medical department has no representation on the General Staff there never can be any team play in an army"—Colonel Goodwin, A.M S, in an address to the United States War College, states as having held the post of A.D M S of two divisions in France that when he has heard staff officers declare a particular A D M S "difficult to manage,' he has considered that a great compliment had been paid to the administrative medical service He observes that the higher the discipline of a unit the more efficiently is its sanitation carried out, and that sanitarily the best conducted troops are the Guards He further notes that to avoid ' a medical breakdown' after an action, the A.D M S must secure information in advance from the headquarters staff For he is always working with a rope round his neck and when the medical breakdown comes as come it will it is he who will be "hanged," so he had better get this delaying of information removed before the breakdown it is rendering inevitable occurs —The same issue of the journal contains an interesting account by Lieutenant-Colonel E L Munson of an outbreak of measles occurring in a military camp in Texas in which the author lays stress on the respiratory symptoms

Archives de Médecine Navale —In the issues of this journal for June and July Dr René Potel, médecin de 1re classe of the French Navy gives an account of an epidemic of typhus fever amongst Serbian soldiers and the Frenchmen who associated with them in February and March 1916 On Feb 1st 2400 Serbian soldiers who had escaped from Serbia after many hardships were embarked at Corfu in the French transport *France IV* for Tunis. There was neither time nor opportunity to clean them before embarkation nor even to give them clothing and they came on board in their rags On Feb 12th cases of typhus began to appear among the French sick berth staff, in all, 14 of the ship s company were attacked These men were on arrival sent to the naval hospital at Bizerta where they being few were completely cleaned and no further cases occurred The 486 Serbian cases were sent to Sidi Abdallah, near by where emergency hospitals had been prepared for them but as they arrived in scores and hundreds little could be at once done beyond washing them and putting them into clean clothes, they were not like the others shaved and so freed from nits and 21 days after their arrival cases of typhus began to appear amongst the medical officers and the orderlies This period of 21 days was occupied, it is suggested three days of it in the hatching of the nits and the development of the parasites therefrom, eight days in the maturation of the cause of the infection within these young parasites and ten days in the incubation of the fever in the bitten human patient Ten days after there had been time to work over all the patients to get them shaved completely and their bedding disinfected no more cases occurred. The cases amongst the Serbians were numerous but mild, those amongst the French few but severe Dr Potel observes that the sanitary measures employed were directed against lice only, and that they brought the epidemic to an end Whence he concludes that it is by lice and by lice only that the fever was spread The measures taken became more rigid as time went on At first men were allowed to keep their purses and tobacco pouches, but later they had to leave all their possessions behind As to diagnosis, Dr Potel notes that this is at first difficult, as there is so much resemblance to enteric The temperature, however, is high and steady without the marked morning remission of typhoid fever, beside the cutaneous rash there is a blue punctate rash on the congested soft palate, there are headache, wakefulness, abolition of the superficial reflexes, and a hebetude which may by persistent provocation be changed to irritation During convalescence, it may be said the pre existence of typhus is shown by exaggeration of the deep and loss of the superficial reflexes, great wasting, poor sleep, and nocturnal pains in the legs In doubtful cases the injection of 40 minims of the patient's blood, intraperitoneally, into a guinea pig will produce in ten days the characteristic symptoms Dr Potel was very fortunate in being able to get an antityphus serum from Dr Nicolle—apparently (it is not definitely stated) the non centrifuged serum of an ass carefully immunised [1] Of 3 cases without serum 2 died, of 31 treated by serum, cases equally grave all but 1 recovered The devoted work of the French medical staff who suffered so heavily in their splendid work for the refugee Serbian soldiers is made clear in the report, from which it also appears that if the embarkation at Corfu had been definitely delayed and spread over two days, while the Serbians were in turn being washed and shaved and embarked, and having their clothes boiled, this epidemic would have been much lighter We learn that a medical officer stood out against receiving the Serbians till these things were done, and if he had had his way his orderlies would have been saved from disease, and his country from much unnecessary expense

Reports and Analytical Records

FROM

THE LANCET LABORATORY

TOILET LANOLINE (WELLCOME BRAND)

(Burroughs, Wellcome and Co Snow Hill Buildings, London, E C 1)

The curious characteristic of dry wool fat of readily emulsifying into a uniform cream with water renders it a valuable skin application Hydrous lanoline is thus easily absorbed by the skin, rendering it supple and smooth without leaving a greasy impression. The sample submitted to us contained, according to our analysis, exactly 30 per cent of water, while it was entirely free from mineral matter On heating, the creamy mass melted and the water and wool fat separated, and after a time a clear yellow oil remained It is pointed out that while this preparation is primarily intended for toilet use it is also suitable for application in many skin conditions particularly as the wool fat employed is highly refined It is delicately perfumed

JARDOX

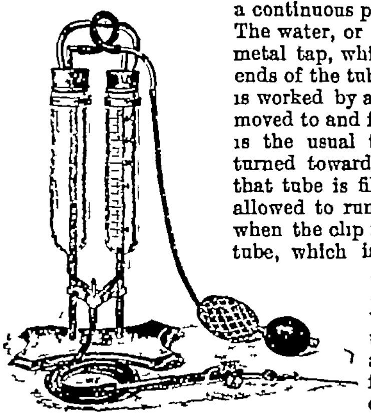
(Jardox Limited, Crystal Palace Works, Anerley, London, S E 20)

Jardox is a viscid meat expression which, in addition to the ordinary extractives and bases of meat, contains a notable proportion of finely divided fibrin, as well as coagulable albumins On analysis the following results were obtained Moisture, 35 00 per cent, total meat derivatives, 55 30 per cent, mineral matter 9 70 per cent The meat derivatives were made up of 50 per cent extractives and bases and 5 30 per cent. of fibrin and albumin The presence also of a notable proportion of proteoses was confirmed, inasmuch as a material yield was obtained on the addition of saturated ammonium sulphate solution The mineral matter was chiefly salt and potassium phosphate The flavour is agreeably "beefy" and not too rich Besides its stimulating properties, this preparation provides a definite food value due to proteoses, fibrin, and albumin, which renders it useful for invalid purposes and also for general use as an emergency restorative

New Inventions.

A ONE MAN "606" APPARATUS

This apparatus is easily portable, easily taken to pieces for sterilisation easily rearranged, and all the parts can be replaced, and it is safe There are two vertical glass tubes connected above by corks to an ordinary spray bellows which by frequent compression give a continuous positive pressure within The water, or "606," runs through a metal tap, which is connected to the ends of the tubes by rubber, the tap is worked by a handle which can be moved to and fro at will—beyond this is the usual tube The handle is turned towards the water side, and that tube is filled up and the water allowed to run until it is free of air when the clip is closed The "606" tube, which is divided into 30 c c and subdivided into 10 c c is then filled with one or more doses, the corks firmly put in and the air pressure fully raised, and, the corks holding the operation can be started Directly the vein is entered the water runs down the glass and the handle can be then switched on to the "606" and the measured quantity allowed to run in The "606" is then turned off, and it is washed in by the water till the colour disappears in the window On the first occasion I gave 22 injections, and I have always found it to work well, and since then I have given 41 in an hour The left hand must always be on the needle and the right hand free to move the handle, &c



The apparatus called the Simplex "606" Infusion Set is manufactured by A Day 8 Albemarle street Clerkenwell E C 1, and is obtainable from all surgical houses

James S Robertson
House Surgeon, London Lock Hospital

A MODIFIED ANCHOR TOURNIQUET

In the ordinary pattern of Samway tourniquet though the anchor catch gives a satisfactory hold, it is not easy to fix the instrument at the required tension nor can it be rapidly detached These shortcomings are due to the lack of any part of the apparatus upon which a firm purchase can be obtained To provide this I have had a handle added in rigid continuity with the anchor The form is sufficiently shown by the illustration It will be found that a tourniquet fitted with this modified anchor can be readily applied at any tension and can be rapidly detached, even when out of sight The pattern shown has been made for me by Messrs Allen and Hanburys Wigmore street, W

Success and Failure in the Treatment of Tuberculosis

GLOOM has fallen on the *treatment* of tuberculosis, at all events in the public mind The keen hopes raised by the open air methods introduced from Nordrach, by the Edinburgh dispensary scheme, and by the Frimley graduated exercises have died down During the years when these pioneer methods were being worked out the death rate from tuberculosis was falling steadily from year to year, and although critics were not wanting to point out that this fall in death rate was nothing more than a continuation of the steady fall already in progress during the last half century, and even possibly the diminution of this rate, yet the feeling was widespread that a new and hopeful era in the treatment of tuberculosis had been introduced How different is the position now Sanatorium treatment is regarded by many as having failed in its promise and succeeded merely in interposing an interval of improvement in the inevitable course of a fatal disease The death rate from pulmonary tuberculosis has risen during the last three years in a way which no thoughtful person can overlook The figures from headquarters are given in another column by SIR ARTHUR NEWSHOLME, who adds an instructive table of the rate for the last three years in comparison with the favourable year 1913 Both 1915 and 1916 show a 12 per cent increase on 1913 in the death rate from pulmonary tuberculosis, and it must be remembered that in a slow disease like tuberculosis the death rate is rather a clue to conditions prevailing in previous years The discouragement extends to all the schemes, set in motion on the recommendation of the Departmental Committee on Tuberculosis in 1912, in spite of a vast amount of trouble and administrative machinery we have not kept pace with the disease The tendency is a natural one to regard the whole of this machinery as useless and to wish it scrapped for something better The contrast is so vivid between apparent administrative failure in regard to tuberculosis and the dramatic success achieved in stamping out enteric fever by means of prophylactic measures, that increasing pressure is being brought to bear on authorities to treat tuberculosis as a contagious disease and the sufferer from tuberculosis as a social pariah to be isolated from his fellows

It may not, therefore, be out of place, even at the risk of wearying the well informed, to return once more to the essential difference between the course of tuberculosis and that of strictly limited acute infections As the late W R HUGGARD acutely observed, the dead house has no bias, and the observations of NAGELI on the prevalence of tuberculosis in hospital autopsies at Zürich have never been challenged Quite recently his figures have been confirmed from another pathological institute in Switzerland by Dr. A REINHART,[1] who found in a series of 360 consecutive autopsies only 13 bodies which did not afford evidence of previous infection with tubercle This indicates that 96 per cent of the ordinary hospital population of Berne, a bleak but not unhealthy city, have had tuberculosis, and of these only 32 had progressive lesions at the time of their death, while 64 per cent had healed foci consisting merely of calcified scar tissue Dr REINHART cautions his readers that the result of hospital material must not be applied to the generality of mankind without due consideration, and that the post mortem material of the war will alone afford conclusive evidence of the extent of tuberculisation, but his conclusion is unassailable that tuberculosis is acquired and recovered from without treatment by a vast majority of civilised people This stamps it at once as a social disease which cannot intelligently be dealt with on the lines of acute epidemic disorders The Departmental Committee, recognising this, set in movement a vast social organisation to deal with tuberculosis, and the question which must be asked is whether this herculean labour has shown any commensurate results The answer is emphatically that neither material for proof or disproof is yet available SIR ARTHUR NEWSHOLME tells us that in 1911 there were 1300 beds available for the institutional treatment of tuberculosis and about 25–30 tuberculosis dispensaries in action During the two years *following* many local authorities were persuaded to establish tuberculosis schemes Then came the war, which put a stop at once to the realisation of any schemes recently initiated and prevented the full working out of those already in action But the war did more than this It brought with it precisely those factors known to have a harmful influence on tuberculosis Obviously the restriction of food supply, which has had such a terrible influence in Belgium and the districts of France in German occupation, has not been a widely felt influence in this country, but the results of mental stress and physical strain have been the same, although in less measure With regard to the fighters themselves, it was contended with some show of probability that the free open air life of the trenches, with abundant food and exercise, might exert a favourable influence on the course of tuberculosis acquired in town life In the full light of his official knowledge SIR ARTHUR NEWSHOLME says No A few consumptives have been able to withstand the strain of active warfare, the majority unfortunately have broken down and he adds that the records already show a material national increase in tuberculosis due to the war

The position, then, is this Tuberculosis is being given a new start while the measures for its control

said with reason, that the latter has been shot in the head and the former has been shot in some other part. Is this a sufficient justification for making their futures so different? We scarcely think so. We are bound to give due weight to the sentimental aspect of the problem, though not at the expense of abandoning our professional view that any measures calculated to enlighten public opinion on the unreality of the insane stigma should be patiently emphasised.

Another point arising out of the discussion must not be ignored, especially as we have reason to believe the Board of Control may be in possession of facts not accessible to the lay public. It is impossible in many cases to tell an epileptic patient by merely looking at him, nor will a routine medical examination necessarily reveal the truth. Such men may therefore be accepted in good faith by the authorities, but before they have been in the Navy or Army a week they may develop fits and be transferred to a Service hospital. They have been of no value whatever from a naval or military point of view, and the appearance of epileptic degeneracy may not be far distant, yet meanwhile separation allowances and the usual privileges are granted. It is possible that in some cases medical officers may have been deliberately deceived for the sake of the monetary advantages. Similarly, in the lucid intervals of certain forms of recurrent insanity men may have been accepted, though only by reason of denial on the part of the recruit or his relatives of the facts of the case. Again, certain forms of mental disease, in an early stage may have been missed by the medical officer for one reason or another. Technically these patients have become sailors or soldiers, but they have passed through no "extraordinary vicissitudes" to develop their disease, quite the contrary. They have been accepted but only as the result of the suppression of material data, and we are not inclined to regard any attempt at discrimination between such and the genuinely traumatic insane as sophistry or refinement. There is at the least, another side to the proposal that all insane Service men should be taken as "Service patients" irrespective of former attacks of insanity, any history of heredity or mental deficiency, or any form of insanity due to syphilis contracted years before the war. We feel it is only fair to the genuine cases that that form of sharp practice which pushes the frankly unfit into the Army for ulterior motives should be exposed, where technical acceptance is due to the holding back of material facts and where the patient's actual service with the colours is numbered by days or even hours. We cannot see that any particular hardship would arise were these cases to be dealt with in the usual routine way of civilian practice. However, we cordially agree with Dr GEMMEL that only good can come by clearly envisaging these various aspects of a most important question, which calls for immediate discussion with a view to practical measures of an acceptable kind, and in regard to which further pronouncement on the part of the Government will be welcome.

Annotations

"Ne quid nimis."

THE WAR EMERGENCY FUND OF THE ROYAL MEDICAL BENEVOLENT FUND

THE aims of the War Emergency Fund of the Royal Medical Benevolent Fund were more precisely defined at their conference last week with members of the medical profession in general. As we have already noted, the chairman described it as a civilian fund to be managed by civilian doctors and with the principal object of assisting men on laying down their medical commissions to rehabilitate themselves in practice. Including the result of the recent appeal, a sum of £7000 is now in hand but the immediate objective is a sum of no less than £25,000, with a probability of finding even this insufficient if only 3 to 4 per cent of the medical men holding commissions prove to need help. It cannot be too strongly emphasised that the War Emergency Fund begins where other funds leave off and that no question of competition or overlapping arises. Proof of this, if proof were necessary, is afforded by the fact that the heads of the Medical Services of both Navy and Army accompanied their regrets for absence at the conference with good wishes for the success of the Fund. Important details of administration rather than questions of principle occupied the main attention of the meeting. Several of those present urged that the Fund should be administered as a loan to be repaid at leisure, and this view gained acceptance in the form "Take this to start you on your legs again, you can return it whenever you like, with or without interest as you please." Decentralisation for the collection of funds was a second point which met with general approval, a speaker stating that a personal appeal through an enthusiastic local leader, however unknown in wider circles, would attain a better response in any district than circulars from headquarters. The value of the help of Local Medical War Committees in making recommendations arising out of their local knowledge was recognised, while keeping steadily in view the necessity for absolute secrecy. The plan for ensuring this secrecy is the investigation of the case of any applicant by a single officer of the Fund, who places the name on a register accessible only to the executive, the application being dealt with in future as a number only. As on previous occasions, the conference wished it to be made abundantly clear that no question of charity must arise in accepting help from the Fund. Of the 12,000 or more medical men who have received commissions some have undoubtedly improved their financial position, while others, for the most part young men in process of building up practices, have suffered to a serious extent. The War Emergency Fund may well be regarded as a pool from which to equalise the war sacrifice made by the medical profession as a whole in so far as money can redeem the loss. The Fund appeals, in the first instance, to the more prosperous in our own profession, and then to a larger public which recognises its obligation to medical science and skill during the war. Such, in brief, was the message of the meeting, and while the Executive Committee of the Fund remains the same for the time being, a large General Committee of supporters was elected to uphold them in their work.

are handicapped And yet another factor tells in favour of the disease on which insufficient emphasis has yet been laid—viz , the restriction on ventilation caused by the Home Office lighting regulations More than 12 months ago Dr S Davies, of Woolwich, attributed the increased incidence of tuberculosis and other respiratory diseases in Woolwich to this cause The habit of the fresh air life, an essential part of the tuberculosis campaign which was just beginning to take hold of the nation as a whole, has received an incalculable setback by the insistence on closely screening windows But there is in all this no cause for depression The mechanism of tuberculosis control is good and only requires to be properly applied The work of the tuberculosis dispensaries of our great cities and such an organised system of control as that under the direction of the Chair of Tuberculosis at Edinburgh are on the right lines Sir Arthur Newsholme is most helpful when he points out the defects of these efforts and their appropriate remedies On the side of the patient the harm comes from delay in applying for treatment until the disease is fully established and his unwillingness even then to accept sanatorium treatment neglect and concealment are still potent factors On the side of the practitioner is the difficulty nowadays of devoting the time necessary for early diagnosis, and a certain unwillingness to refer doubtful cases for consultation to the tuberculosis officer Against the work of the tuberculosis officer is the insufficient staff available for the new service, and the number of experienced assistants is now reduced almost to a vanishing quantity by the war No serious progress can be made without close coöperation between these three essential links in the chain of administrative control—the patient, his doctor, and the tuberculosis officer In certain places where the coöperation has been complete the success of dispensary treatment has been such that undue emphasis has been laid on such minor adjuvants as the administration of certain remedies With the return to normal conditions after the war, with the more complete training of the tuberculosis officer, and greater coöperation with the general practitioner, the administrative control of tuberculosis will come into its own

◆

The Problem of the Insane Sailor and Soldier

Of the various after the war problems already beginning to attract public and professional attention that of the future of Service men who have become insane or otherwise mentally afflicted is not one of the least important It may be taken for granted, in general terms, that the Government and the country desire that all who have broken down while wearing the King's uniform should be treated justly and even generously For there is a feeling that in dealing with those who have suffered most, and who are unable to do anything further for themselves, any error that is made should be on the side of generosity To those acquainted with the handling of the nervous and mental wreckage of warfare on land or sea the inadequacy of the accommodation at present provided has long been noticeable Certain institutions admitting mental cases from a command of wide limits have been more or less crowded out Nor are the numbers of such cases likely to diminish for some time yet Further, a large number, the approximate percentage of which it is at present impossible to gauge, will pass into the category of the chronic or the incurable

From a letter which we publish in another column it will be gathered that the official suggestions, accepted by the Board of Control, for the disposal of such cases are already meeting with criticism It will be seen that the Government propose to provide the required accommodation in the ordinary civilian pauper asylums, with an allowance of 3s 9d above the pauper maintenance rate A mild attempt at further distinction from the pauper insane is to be effected by resort to the term "Service patients", and by a recent order every military case is regarded as a private patient, to be paid for by the Ministry of Pensions until his status has been determined We do not know whether in such institutions the "Service patients" are to be kept in separate blocks or not, although we cannot suppose, as Dr J F Gemmel seems to hint, that they may not be segregated even from the criminal insane One of the objections to such suggested treatment is undoubtedly associated with the fact that in the lay mind there is a stigma attached to insanity and asylums The persistence with which this keeps cropping up is such that it cannot be dismissed airily from consideration, absurd though it may be and is The public have not yet learned that mental disease is nervous disease, or that mental symptoms may be the outcome of pathological processes in the brain whose occurrence elsewhere, say in the liver, would never be regarded with distress or spoken of with bated breath It is a commonplace of practice that the average family will do anything to avoid the certification of the insane relative, and Dr Gemmel appears to welcome the possibility of saving the "Service patient" from "at least documentary evidence of insanity," though he would, of course, admit this can make no difference to the medical facts of the case While, however, the public is not yet educated to regard insanity through the spectacles of the physician, the question of avoiding certification as far as practicable is not to be ignored, especially as the sentimental side of the matter also demands consideration By this we mean that there is something repellent in the idea that some of the men who have fought for us should as a consequence spend the rest of their lives in a lunatic asylum Elaborate schemes are on foot to provide homes and blocks of residences for disabled Service men where they may spend their days by themselves in comparative comfort, hundreds, of another class, will be adequately cared for in such places as the new Star and Garter home, yet the only difference between these men and the unfortunate traumatic insane is, it may be said with reason, that the latter has been shot in the head and the former has been shot in some other part Is this a sufficient justification for making their futures so different? We scarcely think so We are bound to give due weight to the sentimental aspect of the problem, though not at the expense of abandoning our professional view that any measures calculated to enlighten public opinion on the unreality of the insane stigma should be patiently emphasised

Another point arising out of the discussion must not be ignored, especially as we have reason to believe the Board of Control may be in possession of facts not accessible to the lay public It is impossible in many cases to tell an epileptic patient by merely looking at him, nor will a routine medical examination necessarily reveal the truth. Such men may therefore be accepted in good faith by the authorities, but before they have been in the Navy or Army a week they may develop fits and be transferred to a Service hospital They have been of no value whatever from a naval or military point of view, and the appearance of epileptic degeneracy may not be far distant, yet meanwhile separation allowances and the usual privileges are granted. It is possible that in some cases medical officers may have been deliberately deceived for the sake of the monetary advantages Similarly, in the lucid intervals of certain forms of recurrent insanity men may have been accepted, though only by reason of denial on the part of the recruit or his relatives of the facts of the case. Again, certain forms of mental disease, in an early stage, may have been missed by the medical officer for one reason or another Technically, these patients have become sailors or soldiers, but they have passed through no 'extraordinary vicissitudes' to develop their disease quite the contrary They have been accepted but only as the result of the suppression of material data, and we are not inclined to regard any attempt at discrimination between such and the genuinely traumatic insane as sophistry or refinement There is at the least, another side to the proposal that all insane Service men should be taken as "Service patients' irrespective of former attacks of insanity, any history of heredity or mental deficiency, or any form of insanity due to syphilis contracted years before the war We feel it is only fair to the genuine cases that that form of sharp practice which pushes the frankly unfit into the Army for ulterior motives should be exposed, where technical acceptance is due to the holding back of material facts and where the patient's actual service with the colours is numbered by days or even hours We cannot see that any particular hardship would arise were these cases to be dealt with in the usual routine way of civilian practice However, we cordially agree with Dr GEMMEL that only good can come by clearly envisaging these various aspects of a most important question which calls for immediate discussion with a view to practical measures of an acceptable kind, and in regard to which further pronouncement on the part of the Government will be welcome

Annotations

"Ne quid nimis"

THE WAR EMERGENCY FUND OF THE ROYAL MEDICAL BENEVOLENT FUND

THE aims of the War Emergency Fund of the Royal Medical Benevolent Fund were more precisely defined at their conference last week with members of the medical profession in general As we have already noted, the chairman described it as a civilian fund to be managed by civilian doctors and with the principal object of assisting men on laying down their medical commissions to rehabilitate themselves in practice Including the result of the recent appeal, a sum of £7000 is now in hand but the immediate objective is a sum of no less than £25,000, with a probability of finding even this insufficient if only 3 to 4 per cent of the medical men holding commissions prove to need help It cannot be too strongly emphasised that the War Emergency Fund begins where other funds leave off and that no question of competition or overlapping arises Proof of this, if proof were necessary, is afforded by the fact that the heads of the Medical Services of both Navy and Army accompanied their regrets for absence at the conference with good wishes for the success of the Fund Important details of administration rather than questions of principle occupied the main attention of the meeting Several of those present urged that the Fund should be administered as a loan to be repaid at leisure, and this view gained acceptance in the form 'Take this to start you on your legs again, you can return it whenever you like, with or without interest as you please Decentralisation for the collection of funds was a second point which met with general approval, a speaker stating that a personal appeal through an enthusiastic local leader, however unknown in wider circles would attain a better response in any district than circulars from headquarters The value of the help of Local Medical War Committees in making recommendations arising out of their local knowledge was recognised, while keeping steadily in view the necessity for absolute secrecy The plan for ensuring this secrecy is the investigation of the case of any applicant by a single officer of the Fund, who places the name on a register accessible only to the executive, the application being dealt with in future as a number only As on previous occasions, the conference wished it to be made abundantly clear that no question of charity must arise in accepting help from the Fund Of the 12,000 or more medical men who have received commissions some have undoubtedly improved their financial position, while others, for the most part young men in process of building up practices have suffered to a serious extent The War Emergency Fund may well be regarded as a pool from which to equalise the war sacrifice made by the medical profession as a whole in so far as money can redeem the loss The Fund appeals, in the first instance, to the more prosperous in our own profession, and then to a larger public which recognises its obligation to medical science and skill during the war Such, in brief, was the message of the meeting, and while the Executive Committee of the Fund remains the same for the time being, a large General Committee of supporters was elected to uphold them in their work.

LOCAL ARGYRIA DUE TO ORGANIC SILVER COMPOUNDS

THE generalised argyria following the prolonged administration of silver nitrate is well known, and so is the local argyria which follows its local use and also occurs in silver workers But the local argyria due to the local use of argyrol and other organic silver compounds is a recent observation In the *Journal of the American Medical Association* Dr G M Olson has reported the following case —

A woman came under observation in November, 1916 Four years previously she sustained fracture of the nose with laceration of the soft parts extending to the right lower eyelid Argyrol was dropped into the eye, and made its way into the lacerated tissue of the lid, nose, and cheek An unsightly bluish green and slate grey pigmentation resulted for which the oculists were consulted Bichloride of mercury injections were given and, according to the patient, effected a slight improvement For two years the condition had been stationary Dr Olson prescribed hexamine, 5 grains thrice daily The condition improved at once, and in two weeks half the area of pigmentation had disappeared The dose was increased to 10 grains and the improvement continued, but was not so marked After six weeks the drug proved irritating to the stomach and kidneys and was discontinued About three fourths of the pigmentation had disappeared

The hexamine treatment was discovered by an American practitioner, A M Crispin, who published in 1914 a case of universal argyria due to collargol He gave the patient hexamine for a cold and was astonished to find that the pigmentation became several degrees lighter Another American, Davidson, reported in 1916 a case of general argyria due to urethral injections of argyrol and protargol The pigmentation following the application of the organic silver compounds comes on very slowly, but when subcutaneous injections are made the cutis and subcutis are stained at once, and if the skin is thin, as in the eyelids, a bluish green discolouration immediately becomes apparent The danger of argyria is not great, provided certain precautions are taken Intact epidermis and mucous membranes do not take up the silver stain unless solutions are used steadily for a long time But raw surfaces, such as ulcer of the cornea and burns, from which epithelium is absent, readily take up the stain In chronic inflammation the epithelium of the mucous membranes also takes up the stain more readily There is special danger in forcibly injecting the lacrymal duct urethra, and similar places, as the solution may be forced into the loose connective tissue Solutions should never be used near lacerated wounds, and patients should not be allowed to use them unsupervised for long periods The prognosis of general argyria due to internal administration of silver nitrate, in which there is a large amount of silver in the tissues, is almost hopeless But in local argyria, due to organic silver compounds, the amount of silver present is small, and in some patients the pigmentation disappears spontaneously Even in occupational argyria, due to metallic silver, the pigmentation occasionally fades spontaneously Treatment has not proved of much service, the principal remedy has been potassium or sodium iodide given by the mouth Dr Olson considers that the hexamine treatment is promising, but so far it has been tried in only two cases He suggests that it acts by forming a soluble compound with the pigment which is absorbed and probably excreted by the kidneys Under the treatment the stain should diminish in two weeks But as it fades slowly the treatment should be continued for months, with intervals, so as to avoid irritation of the stomach and kidneys

ROYAL SOCIETY OF MEDICINE

THE Royal Society of Medicine has just issued the calendar for 1917-18, which contains much interesting information on the origin, progress, and work of the society, with a complete list of officers, members of Council, sections, and dates of meetings With Sir Rickman Godlee as President (the Past President being Sir Frederick Taylor), the Council has the following list of Vice Presidents who are also Presidents of sections Mr G Rowell (Anæsthetics), Dr Preston King (Balneology and Climatology), Dr H Morley Fletcher (Diseases in Children), Dr H. D Rolleston (Clinical), Dr J Galloway (Dermatology), Dr G Harrison Orton (Electro Therapeutics), Dr G S Buchanan (Epidemiology), Dr Raymond Crawfurd (History of Medicine), Dr A Brown Kelly (Laryngology), Dr A E Garrod, F R S (Medicine), Dr R P Smith (Neurology), Dr G F Blacker (Obstetrics and Gynæcology), Mr J H Badcock (Odontology), Mr W Lang (Ophthalmology), Dr H J Banks Davis (Otology), Dr W Bulloch, F R S (Pathology), Dr R P Smith (Psychiatry), Sir Anthony A Bowlby (Surgery), and Dr W Hale White (Therapeutics and Pharmacology) Dr W Pasteur and Mr H S Pendlebury are the honorary treasurers, Dr Norman Moore and Mr W G Spencer the honorary librarians, and Mr C H Fagge and Dr J C Briscoe the honorary secretaries The secretary, consulting librarian, and editor of the society's proceedings is Mr J Y W MacAlister, into whose energetic dispensation of business no sign of this multiple pressure of work has intruded

OUR DAILY SUGAR

A SERIES of questions and answers published recently in the *Local Government Chronicle* not only illustrate the difficulties which will beset some members of the public in obtaining their authorised portion of sugar in the coming year but serve to remind us also that the work of the Government department responsible for the nation's first experiment in compulsory rationing has been, and will be, no sinecure The questions are, of course, those propounded by readers of the periodical containing them, and a considerable portion of them relate to persons who change their residence frequently, in some cases at every week end, by "going home" or by leaving their homes for change of air Arrangements, it is stated, are being made for those who thus remove from one registered household to another and for others who, having no fixed address, cater for themselves and are constantly travelling They will have to form a code of a comprehensive and ingenious character if they combine to satisfy the requirements of the chronic week ender, of the bachelor and spinster entering the bonds of matrimony after registration, of a mobile anti aircraft unit, and of "a person who has no fixed abode and lives first with one friend and then with another," all of whom are anxious to know what the future may hold in store for them We can conceive the last mentioned nomad being made comparatively welcome in the hospitable circle in which he moves if he were to promise before arriving at each temporary abode that he would contribute his ration to the family stock for general cooking purposes, and abstain from drinking it in tea, coffee, and other beverages This is a form of economy in sugar which hardly seems to be enough impressed upon the public by their many advisers in the newspapers and elsewhere. And yet a large number of persons by choice drink no sugar in their tea, and some, perhaps fewer, omit it from coffee also Many, too, have voluntarily forgone it as a form of "war economy,' and we have not yet heard that either class believes that it has suffered in health thereby, as many believe that they have done through eating "war bread' The temporary shortage of tea with which we appear to be threatened will cause far more inconvenience to all than voluntary abstinence from sugar in it, but may have an indirect advantage through compelling an economy in the latter which many housekeepers will welcome. In respect of sugar, however, and of tea alike, we urge upon all cheerful acquiescence in deprivations which are temporary only and are inevitable Our population suffer in a country which flourished and grew strong long before either tea or sugar was in general use, and which only in a very recent period of its existence has adopted the former as a national beverage

EPIDEMIC POLIOMYELITIS

THE central facts in the bacteriology of poliomyelitis have not seriously been called in question, though the claims of certain streptococci to be regarded as the specific cause of the disease have been urged with some insistence by several investigators These streptococci are frequently found in the central nervous tissues in cases of the disease as seen in man or as artificially produced in monkeys Recent work seems to show that these organisms must be regarded as *secondary infections* since they are unable to produce the lesions of poliomyelitis or to protect against infection by the filtrable virus of that disease, nor do they differ from streptococci isolated from cases of sepsis Interesting researches on the delicacy of the relation which exists between infection and alterations in the meninges and choroid plexus have been recorded by Flexner and Amoss The slight alteration which is caused by lumbar puncture and the injection of such physiological fluids as monkey or horse serum, isotonic salt solution, Ringer's and Locke's solutions, promotes infection with the virus of poliomyelitis which has been introduced into the blood or subcutaneous tissues or swabbed on the nasal mucous membrane Even so minute a disturbance as the substitution of the cerebro spinal fluid of one monkey for that of another may, in some instances, promote infection as does also simple lumbar puncture if attended with the slightest hæmorrhage The same observers found that the intrathecal injection of normal horse serum in protected monkeys caused the passage of protective substances from the blood of the injected animal into the cerebro spinal fluid. There are still many lacunæ in our knowledge of the spread of epidemic poliomyelitis, but some light is thrown upon the irregularities by the discovery that a material is present in the nasal and pharyngeal mucosa of man which can inactivate or neutralise the active virus, and that this power is not found in all cases or at all times in the same individual The poliomyelitic virus has been shown by Flexner to survive in glycerol for at least six years Though much work has been done on the part played by insects in the epidemiology of the disease the evidence as to their importance is still of the slightest

NUTRITIVE VALUE OF BUTTER SUBSTITUTES

AN important point in connexion with the comparative dietetic values of butter and butter substitutes is raised in an interesting paper on the subject appearing in the September number of the *Journal of Physiology* by W D Halliburton and J C Drummond For the purposes of the investigation the butter substitutes were divided broadly into three classes as follows (1) Animal fat margarines (the higher priced margarines), (2) vegetable oil margarines (the cheaper forms of margarine), and (3) nut butter, a class of product forming a comparatively insignificant fraction of the butter substitutes consumed in this country, and which the authors state is prepared exclusively for the use of vegetarians and consequently has a limited sale The experiments were made on rats, but the belief is expressed that the results have a direct bearing upon the dietary of the growing child This belief is, of course, well founded, since experiments on rats have been fruitful in indicating particularly the importance of the presence of accessory growth substances in the dietary As the net result of their investigations the authors conclude that (1) the fat soluble accessory growth substance (vitamine) is present in beef fat and "oleo oil," and is present in margarines prepared upon such a basis Such margarines, the authors consider, are nutritively the equivalent of butter (2) Coconut oil, cotton-seed oil, arachis oil, and hydrogenated vegetable oils contain little or none of this accessory substance, and hence margarines prepared with a basis of these fats have not an equal nutritive value to that of butter (3) Nut butters prepared from crushed nuts and vegetable fats are similarly not equal to butter, while (4) lard substitutes prepared from vegetable oils are equal to lard in their nutritive value, but both alike are destitute of the fat soluble accessory substance. In a well balanced diet the deficiencies pointed out may not be a serious matter, as so many articles of food carry accessory substances, and so a compensation is obtained Curiously enough, this compensation is found in the present war bread as was pointed out in our columns last week Thus while the Government regulation bread contains less starch than wheat flour it is decidedly richer in every other constituent, and particularly in regard to accessory growth substances and phosphorus The importance of a balanced diet is again emphasised in an admirable pamphlet on 'Food and How to Save It" by Dr Edmund I Spriggs, published last week by His Majesty's Stationery Office This consists of a series of articles already issued by the Ministry of Food, which are written in such simple terms as to afford a valuable and instructive guide to the general public The fact however, that some of the fats available to the public are deficient in certain essentials should be carefully considered, as doubtless amongst the poor the fat dietary is largely based on cheap vegetable oils As Professor Halliburton and his co worker Mr J C Drummond, point out, it would be truer economy even for the poor to purchase smaller quantities of an oleo oil margarine if they cannot afford the luxury of real butter But we should like to ask, Are vitamines so difficult to prepare as to exclude the practicability of adding them to accessory free fats, so making up for the deficiency? This question might well receive the careful attention of our food authorities as well as the manufacturers of inactive butter substitutes

ICTEROGENETIC SPIROCHÆTOSIS

Professor Umberto Carpi[1] has had opportunity for investigating over 300 cases of epidemic jaundice occurring in two base hospitals during 1916 from the Isonzo sector The epidemic, which made its appearance with a few sporadic cases at the end of 1915 and reached a high figure in the following January, died out from March to June, and attained its maximum intensity from August to December, 1916 There was a strict parallel between the epidemic of camp jaundice and sporadic cases among the troops in garrison Several interesting facts in Professor Carpi's observations deserve notice He found that the period of incubation was usually 15–20 days, and in some cases 25–30 days or longer, and the question arises whether the disease may not have a still longer incubation period or whether cases of this kind are the result of infection in hospital He found that inoculation of the virus in a guinea pig could give rise to a latent infection capable of manifesting itself only after a long period, in one instance as much as 131 days, and he therefore inclines to the view that in man also there may be a long period of incubation and latency of the infection, and that many of the cases arising sporadically may represent the active phase of an infection contracted some time previously at the original infective focus and slowly developed A further interesting point is the result of the blood examination in Professor Carpi's cases In the initial period of the disease there was a polynuclear leucocytosis and in some severe cases myelocytosis with erythroblasts In the later stages the polynucleosis gave way to lymphocytosis with eosinophilia These peculiarities may afford a differential diagnosis between spirochætic jaundice and certain forms of typhoid and paratyphoid infection which are characterised by leucopenia with lymphocytosis Serological investigations from the point of view of the differential diagnosis between spirochætal and typhoid or paratyphoid infections also afforded results worthy of mention Out of 112 cases it was found that a positive agglutination with typhoid and paratyphoid A was very rare, but somewhat less so with paratyphoid B These results in individuals recently vaccinated do not lend much support to the theory of Frugoni, which attributes the greater part of cases of epidemic camp jaundice to paratyphoid infection None of the cases under observation showed any clinical affinity with either typhoid or paratyphoid Good therapeutic results were obtained by the administration of mixed mercurial and arsenical preparations, as evidenced by the prompt diminution of jaundice, lymphatic gland enlargement, and tumefaction of liver and spleen Even during the febrile period no harmful results ensued from their administration, neither was albuminuria unfavourably affected

As we go to press the Conference of Representatives of Local Medical and Panel Committees has begun its deliberations in regard to the important matters at issue between insurance practitioners and insurance committees

AT its meeting on Monday last the National Council for Combating Venereal Diseases ratified the resolution of its Executive Committee to refrain from recommending artificial prophylaxis

THE CONTROL OF VENEREAL DISEASES

SOME PRACTICAL POINTS IN INTRAVENOUS MEDICATION

WITH SPECIAL REFERENCE TO THE INJECTION OF ARSENOBENZOL PREPARATIONS

BY H W ABBOTT, M.R C S ENG , L R C P LOND

THE treatment of syphilis by the intravenous injection of salvarsan or one of its substitutes is becoming daily of more and more frequent occurrence, and, most probably, in the near future, will be the one recognised method of combating this disease In the vast majority of cases the sufferer applies to the general practitioner for advice and thus it will inevitably become necessary for him to gain proficiency in intravenous medication in order to be able to give his patients the benefit of this, the latest, and probably the best, means of treatment

The operation, though requiring a certain amount of skill, should not be beyond the ability of anyone who cares to give a little time and thought to learning its technique, and it is with the hope of smoothing away any difficulties which may have been encountered that I have ventured to write this paper It is in no wise intended for the specialist, but for that large branch of our profession, the men in general practice, many of whom have probably not had the opportunity of attending any of the post-graduate courses on venereal disease Much of the subject matter of this article has been obtained from personal observation and experience, but a certain amount is based upon, and follows, the teaching of Lieutenant-Colonel L W Harrison and Mr (late Captain) C H Mills, of the Military Hospital, Rochester row, London, S W , to whom my indebtedness is gladly acknowledged

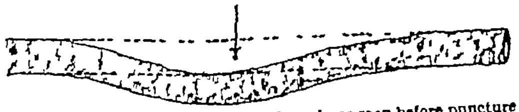
There are several methods employed in passing a needle into the lumen of a vein, but in the present paper I shall confine myself to describing one which is very frequently adopted and which is perhaps, on the whole, the best. Certain preliminary conditions are, however, common to all methods, and much of the success of the operation depends upon the precise fulfilment of these precedent requirements Thus, the patient must be properly prepared, he must be placed in a definite position with regard to the source of light, the skin must be fixed near the site of the injection, &c

Preliminary Considerations

First, then it will be as well to consider these preliminary conditions upon which success so much depends

(*a*) *Preparation of the patient* —This should be very similar to that required for an anæsthetic The patient ought to have fasted for at least six hours previous to the intravenous injection otherwise there is a great liability of his vomiting during or immediately after the operation A smart saline purge is to be given on the previous day, and he should be instructed to avoid drinking much fluid during the 12 hours immediately preceding the injection and to abstain altogether from taking liquids for the last six hours Thus the tissues have lost a good deal of moisture, they are physiologically "thirsty," and simply "mop up" the arsenic from the blood stream after it is injected much to the detriment of the health of the *Spirochæta pallida* the micro organism which causes syphilis

FIG 1



The dotted line shows the course of the vein as seen before puncture of the skin The arrow indicates point of the needle in the overlying skin. The firm line illustrates the displacement of the vein caused by the thrust of the needle though the unfixed skin

(*b*) *Fixing of the skin* —Fixation of the skin, the essential feature of which is that it immobilises the subcutaneous vein, is one of the most necessary factors of success If this be not done the thrust of the needle as it traverses the skin will most probably displace the vein laterally and longitudinally—i e it will produce a kink in it (Fig 1) I need hardly remind the reader that it is extremely difficult to place the bevel of a needle within the lumen of a kinked vein The skin is fixed by pressure exerted on its surface It is convenient to use for this purpose the second and ring fingers, slightly separated, of the left hand, but any digit will serve the thumb in certain positions being extremely useful The pressure should be exerted at a spot about 3 inches nearer to the hand than the site of the puncture, this leaves sufficient room in which to work In fixing the skin, do not drag the vein towards either side but just pull the skin slightly down towards the hand, exactly in the same direction as the course of the vein The integument is thus put gently on the stretch but enough force must not be used to obliterate the lumen of the vein. Now press the skin upon the subcutaneous tissues sufficiently firmly to counteract the thrust of the needle

---

[1] Il Policlinico Practical Section, July 29th 1917

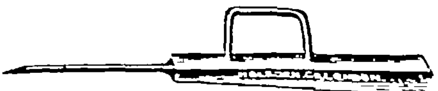
(c) *Position of the patient* —Until fairly recently it was considered necessary for the patient to lie down during an intravenous injection of salvarsan or one of its substitutes, and this recumbent position was maintained for some 24 hours subsequently It has been shown, however at the Military Hospital, Rochester row, that such procedure is an unnecessary precaution. Many hundreds of injections have now been given while the patients have been seated in a chair Moreover, at the conclusion of the operation they have been free from restraint, neither has there been the slightest cause for anxiety arising therefrom In private practice the fact that our patient can be sent away immediately after the operation is completed very much simplifies the matter Let the patient therefore sit on a chair placed alongside a narrow table about 3 feet wide and of a convenient height He is thus sitting sideways close to the table, over which a couple of sterilised towels are placed, and upon these the patient lays his arm It will be seen that, by reversing the position of the chair, either arm can be used for the injection There should be ample light coming towards the surgeon To ensure this the table is placed near a window and the chair will be along that side which is nearer the source of illumination Make the patient lean well back in his chair and a flood of light will stream along the arm showing up, like thick cords, the prominent distended veins

(d) *The tourniquet* —The arm having been bared a length of rubber tubing of 18 inches is applied above the elbow as a tourniquet a piece of lint first being placed round the arm to take the immediate pressure of the tubing Put the rubber on the stretch as it is used and make it tight enough to constrict the veins but not to obliterate the radial pulse Commence by placing the middle of the tourniquet behind the upper arm. Bring the two ends to the front looping one end under the other to keep the tourniquet in position The loop is easier to undo than a knot simply requiring to be pulled. Now instruct the patient tightly to clench his fist If in doing this there is a tendency to flex the forearm put a roller bandage under the back of the wrist and press the fist down over this so as to keep the arm straight

(e) *Position of the surgeon* —When passing a needle into the interior of a vein one can often see the course of the vessel better by looking somewhat horizontally along the arm rather than vertically over the top In this way the course of the veins appears very like the metals of a railroad when looking along its track. The position the operator assumes is somewhat like that which a billiard player adopts when making a shot "

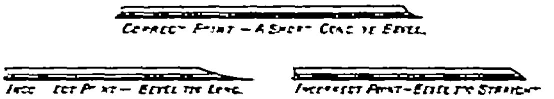
(f) *The needle.*—The best method of holding the needle is to grasp its shoulder between the thumb and first finger of the right hand if an ordinary instrument, say a Weintraud or a Record be employed A much more sensitive touch can be obtained by this method than by holding the instrument in any other way The writer however always uses a needle made for him by the Holborn Surgical Instrument Company, Limited, of Thavies-inn London, E C It has a handle placed on the upper surface of its mount and over the centre of gravity of the instrument, thus giving a perfect sense of balance In practice it is held by its handle when it will be found that the "grip' so obtained imparts to the instrument a greater delicacy of touch than has hitherto been possible and the surgeon can, with the utmost ease give to the point of the needle every gradation of movement which may become necessary in order to ensure its entry into a vein (Fig 2.) The bevel of the needle used for its intravenous injection should not be as long as that of a needle ordinarily used for serum work because it is necessary that the whole of the bevel be in the vein If however the bevel be very long there is the possibility of its being partly within and partly without the blood stream Another point to note is that the bevel ough not to be ground straight but should be concave because this shaped edge more easily picks up the vein wall See Fig 3)

FIG 2.



(g) *The site of the injection* —In the writer's opinion the best vein to select for the injection is the radial, and at a point some three inches below its junction with the median cephalic. Here the radial vein lies over a convexity so that the operator is not working in a hollow, which is frequently the case, especially in fat arms, when one of the veins at the bend of the elbow is selected Further, the radial is one of the most immobile veins in the arm It is also straight and fairly long In selecting a vein it is not wise to choose one of the largest, because a clot sometimes forms after the injection and it is as well not to risk a clot in one of the main channels Again, if a vein of medium size is chosen, we still have the larger ones to fall back upon if we fail successfully to pass the needle into the first vein Before passing the instrument make quite certain, by rolling the selected vessel between the finger and the subcutaneous tissue that there is not a thrombus from a previous injection. If there should be one then select another vein. Clean the needle well before using it, or you may leave a black puncture mark, caused by oxide of iron, which is irremovable

FIG 3.



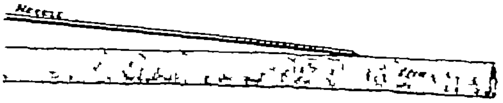
Correct Point — A Short Concave Bevel.
Incorrect Point — Bevel Too Long.
Incorrect Point — Bevel Too Straight.

(h) *Methods of producing venous turgescence* —Sometimes the veins of the arm, notwithstanding the application of the tourniquet, do not stand out so prominently as desired and, in order to achieve this most helpful condition the surgeon may employ any or all of the following methods —1. Hang the arm down for a couple of minutes, at the end of which time apply the tourniquet while the arm is still dependent 2. Subsequent to the application of the tourniquet swing the arm round like a windmill for a dozen times 3. After the tourniquet has been applied, make your patient clench and unclench his fist several times 4 Give the arm half a-dozen really sharp slaps—enough to redden the surface This manœuvre frequently causes the veins to become tense with blood, probably through reflex stimulation 5 Massage the arm from the wrist to the elbow To do this, separate widely the thumb from the rest of the hand, and apply the concavity thus formed to the convexity of the surface of the arm Then rub firmly upwards towards the elbow for half a dozen times The operator will be surprised at the result unless he have already practised this movement 6 Soak the hand and arm in water as hot as can be borne for ten minutes Then apply the tourniquet The limb can be conveniently soaked in hot water by means of an enamelled pail

Insertion of the Needle

Having thus disposed of the preliminary considerations, we now come to the actual injection of the drug The skin having been fixed hold the needle very nearly flat—i e very nearly parallel with the plane of the skin, and likewise in the direction of the vein and immediately over its crown,' by which of course is meant the centre or highest point of its track. With one movement pass the needle bevel upwards, through the whole thickness of the skin and proceed onwards subcutaneously for half an inch

FIG 4



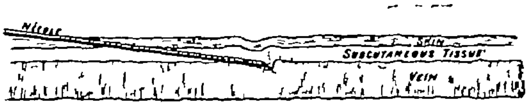
It has been stated by some authorities that the "eye" or bevel of the needle should be downwards—i e., towards the vein but you will find that the needle is much more easily passed through the skin, and it picks up the outer wall of the vessel much more readily when its bevel is turned upwards away from the vein Indeed the bevel of the needle is very like the edge of a carpenter's plane, and should be directed similarly towards any object it is intended to cut (See Fig 4) The point of the needle is now in the subcutaneous tissue between the skin above and the vein below and lies immediately over the vein. At this stage it is very important to define the position of that portion of the needle which is under the skin Without knowing this the inexperienced operator is very liable blindly to plunge about in the subcutaneous tissues, often traversing the vessel, and in any case failing to get the bevel of the instrument into the venous blood stream In order to determine the position of that portion of the needle lying subcutaneously lift the needle bodily up away from the deeper structures towards the surface of the skin and depress the shoulder slightly This movement reveals the exact situation of the whole of that portion of the needle under the skin, because, in bodily lifting the instrument up, you have stretched the skin tightly over it, and thus its position is accurately marked

Now look for the vein and note its course with your eye or feel it with your left hand If by any chance the point of the needle be not lying over the centre of the vein, alter subcutaneously the position of the instrument so that the point does occupy this situation relative to the vein Refix the skin if you have released your hold in order to search for the vein Then simply depress the point of the needle sufficiently to engage the wall of the vessel, but not enough to traverse it, and push gently and steadily along the course of the vessel, the needle *must* pick up the vein, and as you proceed you will feel a sudden "give" in the resistance, a sudden relaxing of the tissues as the needle enters the vessel, and on looking at the end blood will be seen to be flowing Sometimes a distinct "click" is heard as the needle pierces the vessel wall It often takes, however, an appreciable time, something like two or three seconds, for the pressure in the vein to force the blood backwards through the narrow lumen of the needle and flow out at the other end Therefore, do not be in too great a hurry to decide that the bevel of the needle is not within the interior of the vessel

Another phenomenon which will be noticed is the formation of a dimple in the skin, a little distance behind the point of the needle This occurs at the instant when the needle first impinges upon the vessel wall and the mechanism of its production is as follows When the needle, as it is gently pushed onwards, first reaches the vein it does not immediately pierce it, because the actual tip of the needle is really the apex of a triangle, the sides of which are formed by the bevel Now these sides, diverging from the apex, offer a certain amount of resistance to the passage through the coats of the vein Thus the first result of the impact of the needle against the vessel wall is to push it onwards The vein is, however, connected to the skin by the subcutaneous tissue, and as the vessel is pushed in front of the needle it drags the skin after it Finally, however, the needle pierces the coats of the vein, the vessel slips back, the tension between itself and the skin is released, and the dimple disappears The formation of this dimple in a good "rallying point" in the operation of intravenous medication It does not always occur, especially if one is using a fine needle with a very sharp point or if the instrument is thrust into the vein by 'stabbing" at it There is then very little pushing of the vessel in front of the instrument

The formation of the cutaneous depression (' the dimple") *is diagrammatically illustrated in Fig 5*

FIG 5



It is often found that after the application of the tourniquet to an arm practically devoid of fat the veins present immediately beneath the integument—i e, that there is no pad of subcutaneous tissue between the vessel and the skin In such patients the operator will find that as soon as he has passed the bevel of the needle fairly through the whole thickness of the skin the instrument is already within the venous blood stream, the skin and the closely applied vessel having been punctured practically at one and the same time

As soon as the blood is definitely and continuously flowing from the end of the needle the tourniquet can be removed and the instrument connected with the apparatus which the practitioner is using for the injection of the drug

The one certain indication that the bevel of the needle is within the lumen of the vein is blood issuing from the end of the instrument In order to prevent contact with the patient's skin I have found it useful to place a piece of lint soaked in 1 in 1000 hyd et potassii iodidi over the arm at an appropriate distance from the puncture, which thus absorbs the extravasated blood If there be no blood escaping from the base of the needle, then its bevel is not within the lumen of the vein unless of course the instrument be not patent This loss of patency occasionally occurs through a tiny mass of subcutaneous tissue intimately mixed with blood clot plugging the vessel, which condition is sometimes brought about by repeated unsuccessful attempts to pass the needle into the vein If this sequence of events has happened the surgeon will often notice that, although blood be not issuing from the base of the needle, yet it is leaking a little along the track of the instrument, and appearing at the site of the skin puncture, there is thus a great probability of the bevel of a blocked needle having been passed into the venous blood stream It is better in such a case to try venipuncture at another spot Do not withdraw the first needle until the second has been successfully passed, because, when left *in situ*, the needle acts as a plug for the previous puncture in the vessel wall and prevents, to a large extent, extravasation into the surrounding tissues during turgescence of the vein. To obviate any blocking of the needle by other material it is wise always to keep a wire stylet in the instrument when not actually in use

Sometimes, however, blood begins to issue from the base of the needle, proving that the bevel is within the vein but the flow will cease almost as soon as it has begun This phenomenon indicates that the needle has completely transfixed the vein, and consequently that the bevel is now lying in the tissues beyond the distal portion of the vessel wall If this happens it is only possible for blood to flow from the end of the needle during the time that its bevel is passing across the blood stream, as soon as it is beyond the flow stops It is a sign of faulty technique, the instrument having been held at too great an angle with the plane of the skin It can scarcely be too strongly impressed upon the operator who is commencing intravenous medication that the needle should be passed, at all events, through the skin very nearly parallel with its surface If this accident has befallen the operator the instrument should be slowly withdrawn until you find that a position is reached when blood re commences to flow Then you will know that the bevel has been withdrawn from the tissues beyond, and is again within the interior of the vein Should, however, a clot have been formed meanwhile in the stem of the needle, blood will not flow until the obstruction has been removed, the method for doing which is described later in the article.

Injection of the Drug

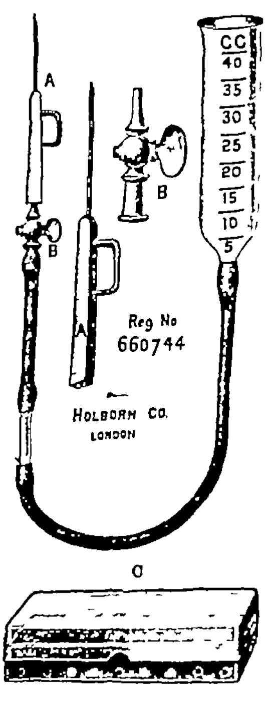
Salvarsan or one of its substitutes may be introduced intravenously either (1) by pumping it into a vein (2) by the action of gravity

Gravity is the better method, because if the needle is not in the vein the solution will not flow at all events but very slightly, whereas one can always force, by means of a syringe or a pumping apparatus, fluid into the subcutaneous tissues At first sight it would seem that if the operator were forcing the solution into the tissues and not into the vein it would be quite easy to recognise the swelling so caused However, many a good operator has failed to do so, especially in a thick arm, and where the point of the needle is deep, and on the far side of the vein Moreover, gravity apparatus is simpler, all that is required being a funnel, a length of rubber tubing with a glass "window" and a tap

After a trial of both methods the writer has now come to use exclusively the gravity apparatus, the only drawback to the use of which very simple contrivance is that an assistant is needed

For the average general practitioner who is, of course, not giving intravenous injections every day the '914' preparations—viz, neo salvarsan, novarsenobillon, neo kharsivan &c—are preferable to the "606 preparations, because salvarsan and its substitutes have to be rendered alkaline before they can be used, whereas the others are sent out already alkalinised moreover as they are extremely soluble in water there is absolutely no technique required in order to form an alkaline solution All one has to do is to empty the contents of an ampoule of, say, novarsenobillon into a vessel containing distilled water, solution takes place immediately and the drug is ready for injection

FIG 6



Salvarsan has not given me any better results than novarsenobillon and for many months now I have exclusively used this latter preparation with the happiest effects on the patients In practice it is dissolved in 20 c c of distilled water, with which it forms a perfectly clear yellow solution The glass funnel (Fig 6) employed is of 40 c c capacity, marked in 5 c c 's, the rubber tubing measures 40 inches complete with the window, which is situated 3 inches from the end To the extremity of the tubing is fitted a Harrison s tap (B), which makes a perfect joint with the special needle (A) I have devised, or with a Weintraud's needle This apparatus is very conveniently kept in a strong metal nickel plated box which has been specially designed by the Holborn Surgical Instrument Company, Thavies Inn, London, E C, for sterilisation by means of boiling The box is of such a size *that if one does not happen to have a* steriliser handy it can be put into an ordinary saucepan (See Fig 6, C)

If the practitioner prefers to use 606 preparations—i e, salvarsan, kharsivan, arsenobillon, &c —*then the funnel* should be of 300 c c capacity, because the best dilution of salvarsan is about 1 decigramme to 30 c c of water, hence 0·6 gramme will require 180 c c to dissolve it, otherwise the technique remains exactly similar The tubing is emptied of air by allowing saline to run through This can be very expeditiously accomplished by first lowering the funnel containing the saline until it becomes the most dependent part, then as the *funnel is gradually raised again* the fluid "chases" the air of the tubing As soon as the needle has been passed into the vein the tap is connected, turned on, and a little saline allowed to run into the vein, then the solution of novarsenobillon is poured into the funnel and the saline renewed just before the last of the solution has disappeared As soon as the surgeon sees that the fluid passing along the "window" has changed colour from yellow to white he will know that all the drug has passed into the vein and he is now only injecting saline solution If the medical practitioner is not situated near a hospital, where, of course freshly distilled water and normal saline made therefrom can be readily obtained, he will be able to get both from Messrs Allen and Hanburys, of 7, Vere street, London, W, or the Holborn Surgical Instrument Company The distilled water supplied by the former under the name of "Apyrogen" water is specially prepared as a diluent or solvent of substances for intravenous injection It is distilled in a Jena glass apparatus and is free from water toxin The distilled water or normal saline is put up in sealed amber glass tubes ("azoules") of a capacity varying from 10 c c to 250 c c, and can be kept for an indefinite period The firm distil nearly every day, so that fresh solutions can always be obtained, but I have used distilled water and normal saline of their manufacture over three months old for intravenous medication without the slightest febrile reaction, although the temperature was taken morning and night for one week after the operation These ampoules of distilled water, normal saline, &c, are kept in stock by the Holborn Surgical Instrument Company

While the injection is being given it occasionally happens that the flow ceases This may be due to either of the following causes 1 The eye of the needle may be pressing against some part of the vein wall, the remedy for which is to revolve the needle 2 A clot may have formed in the lumen of the needle To remove this obstruction disconnect the needle from the apparatus Constrict the venous circulation, pass a stylet *down the lumen of the* needle so as to loosen the clot, when the venous pressure set up by constricting the veins will drive the clot out of the needle, and the operation may be resumed 3 The bevel of the needle may be out of the vein This can be verified by a manœuvre similar to that used under heading 2 If after constricting the venous circulation and clearing the lumen of the needle no blood issues from the end of the instrument, then the eye is not in the *lumen of a vein*, and a fresh puncture had better be made, unless by moving the needle backwards or forwards one can replace the bevel of the instrument within the blood stream, as is evidenced by the blood flow After the injection is completed the patient has a pad of sterilised lint placed over the puncture, the tap is turned off, the needle is withdrawn by a quick movement, and he holds his arm vertically upwards for a couple of minutes, keeping light pressure on the pad, which is then removed The site is now cleansed with a solution of 1 in 1000 hyd et potassii iodidi and painted with a solution of iodine 2 per cent in spirit, as was also done immediately preceding the puncture

Finally, a piece of rubber plaster an inch square, with a tiny piece of boracic lint in the centre to cover the actual wound, is applied, and the dressing is complete The arm should not be flexed at the elbow for one hour after the injection, so as to prevent blood being *forced from* the puncture in the vessel wall into the subcutaneous tissues

The patient is now free to go home, and should not indulge in any form of strenuous exercise for a couple of hours, indeed, it is better when he arrives home to lie down for this period

F t = Faint trace.

There were no returns from Victoria Park London station for April and May and at Tollcross Park Glasgow owing to an accident the April sample was lost.

"Tar" includes all matter insoluble in water but soluble in CS_2 "Carbonaceous" includes all combustible matter insoluble in water and in CS_2 "Insoluble ash" includes all earthy matter fuel ash &c. One metric ton per sq kilometre is equivalent to: (*a*) Approx 9 lb per acre; (*b*) 2·56 English *tons* per sq mile (*c*) one gramme per sq metre (*d*) 1/1000 millimetre of rainfall.

The personnel of public health authorities concerned in the supervision of these examinations and of the analytical work involved remains the same as published in previous tables

THE ARMY COLLECTION OF WAR SPECIMENS

THE OPENING OF THE EXHIBITION

AN exhibition of the Army collection of war specimens was declared open on Thursday, Oct 11th, at the Museum of the Royal College of Surgeons of England by SIR ALFRED KEOGH, Director General of the Army Medical Service, who, at the same time, was presented with the *Honorary Fellowship* of the College With reference to this presentation an interesting fact is revealed by the archives of the College Many years ago Sir Alfred Keogh had actually received his number in the examination room of the College, when sitting for the Fellowship, at which point he was unexpectedly called up for foreign service, and had to discontinue the examination

The ceremony of presentation took place in the presence of a large number of leading surgeons and physicians and medical officers serving with the Navy and Army, as well as of notable civilians In a brief speech SIR GEORGE MAKINS, President of the College, recalled to the meeting Sir Alfred Keogh's distinguished services to his country as the head of the medical department of the Army in the South African War, as Rector of the Imperial College of Science and Technology, and now as Director General of the Army Medical Service in the greatest war which the world has ever known

Sir Alfred Keogh's Address

SIR ALFRED KEOGH, after acknowledging the honour that had been done to him personally, as well as to the Service which he represented, declared the exhibition open in a brief address, in which he described the stages in the movement which had resulted in an increasing and most valuable store of pathological objects As early in the history of the war as November, 1914, he said, a committee was constituted under his presidency to compile a medical history of the war, one of whose aims was to collect from casualty clearing stations and military hospitals examples of the diseases and wounds being endured by the soldiers in order that the best means might be adopted for their treatment Specimens in illustration of these diseases and wounds would constitute an original and reliable source of knowledge for all time The Army Medical College at Millbank, overworked and understaffed at the beginning of the war was not in a position to undertake the formation of such a collection as the Medical History Committee had in view, and in May, 1915, Dr Walter Morley Fletcher, secretary of that Committee, asked the assistance of the Council of the Royal College of Surgeons of England who at once placed the Museum staff and workrooms of the College at the disposal of the Army Council In January, 1916 Lieutenant-Colonel T R Elliott was placed in charge of this particular service in France, and specimens began to arrive in numbers, the willing coöperation being secured of younger pathologists attached to the clearing stations and hospitals in France—namely, Captain Herbert Henry Captain H W Kaye, Lieutenant T G Shore, Captain G Richardson, Captain Adrian Stokes, Captain W S Lazarus Barlow Captain E M Cowell, Major J W McNee, and Captain A. Petrie Consignments from Egypt representing the diseases and wounds of the campaign in Gallipoli were sent by Captain G B Bartlett, and proved of particular value In the spring of 1917 he appointed Sir John Bland Sutton to organise the collection of specimens from hospitals at home—especially hospitals at which particular kinds of wounds are being treated, and in that direction also said Sir Alfred Keogh, the objects of the Medical History Committee were being fulfilled

The credit of holding an exhibition of the collection while the war is still going on was attributed by the Director General to Sir Arthur Sloggett, Director General of Medical Services in France, who urged that in this way the exhibition of specimens would have an immediate educative value On the question being referred to the Council of the Royal College of Surgeons of England, the College said Sir Alfred Keogh, at once made arrangements to proceed to the preparation of specimens for exhibition, the Medical Research Committee giving financial assistance Mr S G Shattock, pathological curator to the College and his assistant, Mr Cecil Beadles, undertook the dissection, examination, and exhibition of wounds in the various systems of the body Colonel F M Caird, Colonel Sir R Jones, Captain E M Cowell Captain Raymond Johnson Sergeant F A Izzard (of the Pathological Museum of the University of Cambridge) Captain G Richardson, Mr R H Burne, Captain H E Gamlen, Dr F Stoney Captain F A Hort, Dr Colin Mackenzie, and Sergeant A K Maxwell were among those mentioned by the Director General as having in various capacities assisted to make the collection thoroughly representative, while he added that special thanks were due to the conservator of the Hunterian Museum, Professor A Keith, who assumed responsibility for the description and arrangement of macerated specimens illustrating the lesions inflicted by modern missiles so far as bones and joints were concerned

The Director General closed his address by making a special reference to the exhibitions of plastic surgery supplied from the Queen's Hospital, Sidcup, where admirable sketches have been made of before and after conditions by Professor H Tonks, F R C S, with models and casts by Private J Walkley Edwards, from the Military Orthopædic Hospital, Shepherd's Bush, represented by casts and drawings of deformed limbs before and after operation, and from No 13 Stationary Hospital in France, whence have come a remarkable series of models, for which Major A Charles Valadier and Captain H L Whale are responsible, showing war wounds of the jaws and the means which have been adopted for their treatment To an extensive series of skiagrams of face and jaw injuries from the Croydon Military Hospital, sent by Colonel W T Lister, the Director General also called attention He then declared the Museum open

The Collection of War Specimens

Three rooms in the Hunterian Museum have been given up to the exhibition of the Army medical collection Room 1 contains the section illustrating general means of wound prevention and the specimens of bone injury Under the heading of Means of Protection we find metal helmets, breast plates, masks and respirators, several helmets being shown bearing evidence that the heads of the wearers had been saved from mortal wounds We next have specimens of wounds of the vault of the skull, among which are remarkable examples of extensive destruction, of perforation in all the diameters, of gutter wounds, and especially some interesting injuries where a very small missile has produced a far larger fracture than could have been expected, and other cases where a blow has caused a fracture of the inner plate of the skull, the outer plate remaining intact There are in this room some notable specimens of injury also of the base of the skull and spinal cord, the upper and lower limbs and pelvis

The second room contains specimens prepared by Mr Shattock and Mr Beadles, and it is here that the effective characters of the wounds met with in modern warfare may be studied, both in their immediate and in their remote effects Examples are set out derived from former wars—chiefly dried or bone preparations, also examples of gunshot wounds culled from civil practice There are specimens from soldiers who fought with Sir John Moore in his retreat to Corunna, there are a few examples from Waterloo, and more of the wounds and injuries of the Crimean War and there is quite a good series from the Austro Prussian and Franco-Prussian wars In those wars the same type of bone injury and the same septic inflammatory sequelæ may be noted, as is to be observed in the specimens of the present war, for the wounds produced by shrapnel and by shell fragments are of the same nature now as in former wars, the septic sequelæ are also the same In this room are placed a number of models obtained by the late Sir Victor Horsley from his experiments to demonstrate the explosive effects of high velocity bullets Such bullets were fired into blocks of soft clay, the models represent the track of the bullet in the clay In this room the study of modern military wounds can be made—wounds of entrance, wounds of exit wounds at various stages after the date of infliction, in various stages of healing, and in various stages of sepsis There are specimens of "excised wounds"—from cases where the surgeon has sought to remove the injured and infected tissues as soon as possible after the date of infliction A series illustrating injuries to the chest, pleura, and lungs with the various sequelæ which may follow such lesions, is of great interest There is one very remarkable injury of the heart, the anterior wall of the right ventricle is extensively lacerated—yet the officer, a member of the Flying Corps, brought his machine safely to earth! There is a very complete representation of vascular injuries, selected and recorded by Sir George Makins

Injuries of the bowel, stomach kidney genito urinary tract, spleen, spine, larynx, and lung come next for exhibition Certain specimens will be bound to attract serious study as well as reflection They represent the lungs of men who suffered in the first cloud of poisonous gas sent over our lines by the enemy early in 1915 at Ypres The effects of that poison on the whole respiratory system may be studied at all stages, early and late On the same stand are recorded the changes which become apparent in the kidney in cases of trench nephritis Here, too, are represented the conditions, organic disturbances, and disorganisation produced by the *Bacillus aerogenes*

In one group of specimens are shown successful operations of a general kind, as distinguished from those upon special parts like the face and mouth This group comprises successful removal of injured kidney or spleen, of pieces of wounded blood vessels, cases where vessels have been successfully sutured, the successful removal of wounded loops of the intestine, artificial union of the fractured ends of bones, removal of large fragments of bone or even entire bones, such as the astragalus and scapula, resulting in the saving of limbs

In the third room there are hung on the walls a series of drawings by Sir Charles Bell, made in Belgium when he was treating the wounded from Waterloo, and in company with them will be found a wonderfully graphic series of sketches by Colonel F M Caird representing certain conditions studied by him in France such as the various stages in the development of "trench foot" There are also rapid drawings of the conditions resulting from guillotine amputations and pictorial notes of the effects of Yperite, one of the poisonous offensive German gases

Then follow, on the same wall, a collection of Sergeant A K. Maxwell's drawings, accurately and minutely detailed records of clinical conditions, seen in our military hospitals in France To the expert each drawing tells its own story, for the less expert the attached explanatory cards will be of service There are also here some excellent drawings by Mr S A. Sewell, who is well known as an illustrator of pathological subjects

At the north end of Room III, close by the door entering into the Museum Hall are placed a series of specimens for which Major Valadier, R.A.M C (No 13 Stationary Hospital B.E.F), is responsible In this work he has had associated with him H L Whale R.A M C They illustrate the nature of the jaw wounds and facial injuries which have undergone treatment at that hospital with the results obtained by operation The exhibits include plaster casts, excellent photographs (many of them in colour) X ray photographs, and a set of wax models of high workmanship

A group of casts and models obtained from the Military Orthopædic Hospital Shepherd's Bush, follows The condition of disabled and deformed limbs before and after treatment are shown by means of plaster casts, the treatment adopted, splints, &c, are represented by means of models

Next we have an exhibit of great interest from Queen's Hospital Sidcup (formerly Cambridge Hospital, Aldershot) Wax models, plaster casts and particularly a series of strong and vivid drawings by Professor Henry Tonks, F.R.C S, of the Slade School of Art depict for the visitor the facial deformities which Major H. D Gillies and Captain J L Aymard are called on to treat, the methods which they invent and adopt, and the degree of success which attends their efforts The models and casts are the work of Sergeant E Phillips and Private J Walkley Edwards, who are attached to Queen's Hospital

On a stand in the centre of the room, immediately in front of the Hunter statue by Weekes, is placed Colonel W T Lister's collection of injuries and wounds of the eye Here may be seen the very numerous forms of lesions which affect the eye in modern warfare—rupture of the eyeball from various causes the lodgment of missiles, and the pathological sequelæ A series of drawings elucidate the functional and clinical disturbances which were observed in each case

Arranged along the centre of the room is a large collection of casts models, and splints from Queen Alexandra Military Hospital Millbank sent by Captain F A. Hort R A M C

Colonel V Soubbotitch of the Serbian Army Medical Service, has placed on exhibition his splint apparatus for treatment of fractures of the lower limb

There can be no doubt that the policy of holding an interim exhibition of the collection in the stage in which it now is will be of remarkable value. There is enough material at present to give the result of collective skill, men will be able to learn from each other's ingenuity, and to avoid each other's errors As the official catalogue of the Museum says It is when one surveys these collections that one ardently wishes that military surgeons of former campaigns had taken some pains to preserve the medical and surgical conditions they were called on to face It is so hard for a surgeon to realise that the conditions he is only too familiar with in the heat of a campaign are unknown to those who do not share with him the labours of the field and will also remain unknown to those who have to undertake the care of soldiers in future times unless a record is made. There cannot be any doubt that in our former wars we have been too apt to attend to the medical exigencies of the campaign and when it closed to bury our experience instead of consolidating it for the use of a future time and generation

Correspondence.

HOME-BRED MALARIA

To the Editor of THE LANCET

SIR,—Dr H B Newham has done well, in your issue of to-day, to call attention to the importance of distinguishing recurrences in soldiers from infected countries and the true home bred malaria I write to urge the most careful study of suspected cases of the latter A few have occurred and there are sure to be others, as there are hundreds of malaria patients in the country and the anopheles is widespread There are no grounds for alarm A colony of patients from Salonika has fluttered the academic dove-cotes in Oxford where mosquitoes are prevalent—even anopheles have invaded the bedroom of the Regius Professor of Medicine! Every precaution has been taken by Major Ormerod and Captain Dale, under the direction of Sir Ronald Ross, and, so far as I know, no infection has occurred In temperate climates districts from which malaria has disappeared have not, to my knowledge, been reinfected Italian labourers brought the disease to the New England States and there were a few cases but no serious outbreak, nor was the progressive fall in the incidence of malaria in Baltimore interrupted by the importation of many infected Italians The slight risk, then, from our malarial soldiers in this country may be faced cheerfully The same may be said of Canada, to which country many infected soldiers have returned Parts of the Province of Ontario were hot beds of the disease, which within my memory has disappeared from the districts about the western end of Lake Ontario and the northern shores of Lake Erie The marshes are there and the anopheles are there but the disease has gone. As in parts of Italy, the important factor appears to have been the cinchonising of the inhabitants I retain lively recollections of the buzzing ears of my boyhood from the large doses of quinine administered to us in the spring and autumn —I am, Sir, yours faithfully,

Oxford, Oct 13th 1917 WILLIAM OSLER

"ANOTHER CASE OF MALARIA CONTRACTED IN ENGLAND"

To the Editor of THE LANCET

SIR,—In my note published under this title in your issue of Oct 6th I should have stated that there was no history to be obtained of a previous attack of malaria or of any illness suggestive of malaria Undoubtedly the possibility suggested by Dr H B Newham in your last issue of a primary attack in Salonika cannot be excluded, but this is exceedingly unlikely and in view of the publication in your columns of other cases of malaria contracted in this country there seems no good reason for assuming an explanation so much more improbable I am, Sir, yours faithfully,

R LOY WILCOX

North Western Hospital N W Oct 15th 1917

THE GERMICIDAL POWER OF FLAVINE

To the Editor of THE LANCET

SIR,—Professor R T Hewlett, in your issue of Sept 29th, offers some criticisms of our work on flavine.[1] His conclusion is, firstly that from his experiments—

"The germicidal value of flavine comes out very much lower than that stated by Browning and his co-workers The difference between the two sets of results is probably due to the use in my experiments of a number of organisms much larger than that employed by Browning and his co-workers

This demands several observations 1. Professor Hewlett ascribes to us the use of an amount of organisms 12 times less than we actually used, he has evidently misread our original work but this becomes a minor point in view of the fact that in our second communication (of which Professor Hewlett was cognisant but to the substance of which he makes no reference) we had already published our work with larger numbers of organisms, which, so far as one can judge from Professor Hewlett's paper, quite equalled the amounts employed in his experiments 2 Professor Hewlett knows very well that the "*germicidal value*" affords significant information only when several antiseptics are compared under precisely similar conditions In our original *communication* we gave the comparative values, as obtained in repeated tests, from which the high potency of flavine (acriflavine) was clearly apparent Now Professor Hewlett finds fault with our results in the case of flavine, but he does not accuse us of giving unjust figures with regard to the old antiseptics, and it is by *the latter* that the comparative potency of flavine is estimated Further, in his own work on flavine he omits all comparisons, we feel sure that Professor Hewlett would not desire readers to believe that he wished them to accept his statements as mere dogmatic assertions and yet that is in effect what he does The general medical reader, who is himself without laboratory facilities can only draw conclusions from the data afforded, and Professor Hewlett omits half of the data which are necessary in order to support his contention that we have exaggerated the potency of flavine Again, Professor Hewlett raises the old point that the action of an antiseptic when mixed with a quantity of pus affords an important indication as to its therapeutic efficiency in an infected wound From the point of view of use as a test medium, pus is so extremely inconstant in composition that results vary enormously, *but, as on a previous occasion,*[3] *we can only repeat that any* surgeon who treated infected wounds by mixing up antiseptic with the pus contained in them, would entertain a curious idea as to his functions !

---

[1] Browning Gulbransen, Kennaway and Thornton Brit Med Jour vol i 1917 p 73.

[2] Browning Gulbransen and Thornton ibid. vol. ii., 1917 p 70

It seems, however, that the real meaning of Professor Hewlett's work is an attempt to give expression to the view that a substance which is to possess any therapeutic value as an antiseptic must *rapidly kill* organisms The time hallowed tests employed in the standardising of antiseptics of course gave information on this point and almost on nothing else, the practical inefficiency of the substances, which were accredited by such tests e g phenol and mercuric chloride when it came to putting an end to suppuration in infected wounds or to preventing its occurrence, is well known Now, we have shown that one of the pre eminent qualities of the flavine bodies is their *antiseptic* power in the true sense of the word, i e, their capacity—in a serous medium, such as exists on the surface of a wound which is subjected to the ordinary procedures of surgical cleansing—for inhibiting the activity of organisms in very high dilutions, which are relatively harmless to the tissues This combination of desirable properties in one substance is new, but the idea of antiseptic action is not new, the conception of its value appears, however, to be novel to those who have concerned themselves with the cleansing of rubber gloves, sterilisation of infected rooms or sputum, and other common applications of antiseptics (purposes for which we have never recommended flavine), and, being novel, it seems to be either misunderstood or else regarded as odious according to the temperament of the critic[4] We shall however, endeavour to pursue our search for those properties of antiseptics which can be determined in the laboratory and which are of use as indicating substances of therapeutic value and we shall be content to be judged in the long run by the massed opinion of those who are bound to rely on such adjuncts in the treatment of their patients We do however, deprecate destructive criticism, which contributes little or nothing to advance towards the solution of a most urgent problem, but which almost seems devised—however unintentionally—in order to "scare off" those who might be inclined to give an unbiassed trial to substances for whose utility in practice there is already a great body of evidence

I am, Sir, *yours faithfully*,

C H BROWNING

Middlesex Hospital Oct. 11th 1917

WAR DEAFNESSES

To the Editor of THE LANCET

SIR,—In a leading article on War Deafnesses in your issue of Oct 13th you refer to a paper of ours which appeared in THE LANCET of the previous week Two criticisms call for reply Firstly, you state your belief that 'any other powerful stimulus applied during the removal of the subconscious determination against hearing would have been as effective as suggestion proved," but you do not *give any idea of the nature of such stimuli* Both of our cases had been treated without success for several months before we saw them by all kinds of powerful stimuli, and we applied every means we could devise before resorting to the pseudo-operation, the instantaneous and complete success of which surely justified the method There is no question of its "frequent" use, as we have only applied it in the very exceptional cases in which all other treatment, such as simple re education and persuasion, or suggestion with or without the aid of electricity, whilst awake, asleep in the hypnotic state, or under light etherisation had failed

Secondly, you express doubt *as to the correctness of our* conclusion that total deafness associated with continued excitability of the posterior labyrinth is evidence of hysterical *deafness*, because '*two cases* are quite an *insufficient basis* for such a generalisation" But our conclusion is based on over 200 cases, not on the two cases which we quoted in detail only because of the exceptional interest attached to the dramatic manner in which they were cured Before our conclusion can be rejected some very much stronger evidence is required than a bald statement to the effect that "cases of mild labyrinthitis occur in which there appears to be total deafness, but in which the canal reflex can still be excited" What is the evidence for this? Our experience teaches us that in such cases the mild labyrinthitis leads to *mild deafness, the complete deafness being due to the* addition of an hysterical element This is a matter of extreme practical importance as in such cases we have always succeeded in removing the hysterical element by suggestion so that partial hearing was noticed, sometimes many months after a diagnosis of permanent total deafness had been made elsewhere On the other hand, acceptance of the notion that mild labyrinthitis may lead to complete deafness must result in the neglect of such treatment and the consequent perpetuation of the condition There can thus be no question *that from the patient's* point of view *our* conclusions and the results which follow from these are infinitely more desirable than the pessimistic view taken in your leading article

We are, Sir, yours *faithfully*,

ARTHUR F HURST,
E A PETERS

Netley Oct 15th 1917

*** The success in the hands of Major Hurst and Captain Peters of the pseudo operation as a sequel to a course of suggestion in the two cases cited is so striking that others will undoubtedly follow in their steps and we therefore expressed the hope that some other stimulus less derogatory to the status of surgery might be found equally efficient The *existence of cases of total deafness* with retention of canal excitability is a matter of pre war experience —ED L

INSANE SAILORS AND SOLDIERS

To the Editor of THE LANCET

SIR,—The Board of Control has issued a circular with reference to "Service patients," or, in other words, sailors and soldiers who have become insane or are *otherwise* mentally affected To suggest, as has been done, that asylums would in any case have had to receive insane sailors and soldiers as paupers and keep them as such is *introducing* into the question the lowest argument of all—the pecuniary one And the question is not yet and by no manner of means settled At the present moment insane soldiers are being admitted to county asylums as pauper lunatics through the medium of the Poor law

I wish to comment on the Circular of Instructions issued by the 'Board of Control" on June 27th of this year relating *to the classification and* treatment of insane sailors and soldiers as "Service patients" Do not let us, then, *obscure* the issues by wondering what we are to do with insane sailors and soldiers after the war and how to cut their cost of maintenance to the lowest possible limit, which *seems to* be the end in view The question of cost of both present and future accommodation and *maintenance* ought not to be approached in a parsimonious spirit and yet it is at the root of the matter, because up to the present the Government has shown no desire to build asylums *for* the accommodation of insane sailors and soldiers, nor to provide for their accommodation other than in pauper asylums

But the nation's indebtedness to those broken men calls for provision for them other than in pauper asylums and in association with pauper and even criminal patients. The mere fact of giving them the cognomen of "Service patients" and paying for their maintenance at a little over the pauper and under the private rate will not dispauperise them in any sense of the term. Without labouring the point or entering into actuarial details, the allowance of 3s 9d above the pauper maintenance-rate is insufficient to clear them of the taint and stigma of pauperism.

---

[3] Ibid 1917 I p 177

[4] See Browning THE LANCET Sept 15th 1917

To my mind there appears to be a very simple solution of the difficulty. Let the Admiralty and War Office at once decide that no insane sailor or soldier be discharged from either service until some months after the war has ended. In this way they can be detained under the Naval and Military Acts, and without certificate of insanity, in military hospitals or in places taken over as such. They will thus be saved from at least documentary evidence of insanity—the insanity which, but for the extraordinary vicissitudes through which they have passed, would in many cases have never occurred. Allocate, therefore, one or a portion of one of the asylums taken over by the War Office as military hospitals for this purpose. This would assure the relatives that these patients were not associated in any way with the pauper and criminal insane in pauper asylums. The Government apparently wishes to avoid the expense of the erection and upkeep of an asylum of its own; it prefers to pay for its insane soldiers at a maintenance rate that still keeps them within the confines of pauperism, and it is apparently willing that they associate with the pauper insane. It shelves its obligation in this way. And the Board of Control has apparently acquiesced. An asylum taken over by the War Office and devoted to this purpose would, of course, as time goes on, have an annual diminishing number owing to death or recovery, and would in the natural course of events, as these changes took place, revert to its original owners—the Asylum Committee—and to its original purpose, the accommodation of pauper lunatics. Any argument that with diminishing numbers this would entail the remainder being kept at an extravagant cost may be dismissed as puerile, for surely it is not beyond the official mental capacity to conceive that a smaller building could be taken over, and, further, the same objection, if objection it be, applies in the case of asylums and other buildings taken over for the wounded. In any case the Government will require after the war to erect an asylum for insane soldiers, as the present Government ones will not have nearly sufficient accommodation.

If the policy of allocating one or a portion of one of the asylums referred to were adopted, for at least the period of the war, the only possible objection would be that friends owing to great distance could not visit the patients. All war, however, inflicts hardships, and even in time of peace how many hundreds of soldiers serving abroad do not see their friends for many years. Moreover, to my mind all insane sailors and soldiers should be accepted as "Service patients" from the commencement of the attack, and quite irrespective of former attacks of insanity, any history of heredity or mental deficiency, or any form of insanity due to syphilis contracted years before the war. There must be no inquiry into antecedents. The country has enlisted and made use of these men in its defence, and there ought to be no discrimination in order to avoid responsibility. No such sophistries and refinements hold in the "Workmen's Compensation Act." If all insane sailors and soldiers are not classed prior to admission to an asylum as "Service patients," irrespective of family history, former attacks of insanity, insanity due to syphilis, epilepsy, &c., there is bound to be further agitation and trouble.

Again I say the Government should give a clear pronouncement on these points.

I am, Sir, yours faithfully,
JAMES F. GEMMEL.

THE TREATMENT OF ENURESIS

To the Editor of THE LANCET.

SIR,—Any addition to our present methods of treatment of this distressing complaint is of value to the medical profession. I should like to be permitted to state that, following the advice of my friend Dr. R. C. Mullins, of Durban, I have successfully dealt with in the Genito-Urinary Department of Guy's Hospital a fair number of cases by a very simple form of treatment of which I had not heard previously to 1914; also I have not found anyone who was familiar with it since that year, although, doubtless, many of your readers have tried it. The method consists in the insertion of a catheter into the bladder and running fluid slowly through into that organ, at a very low pressure. At first only that amount of fluid which the patient can tolerate (say three ounces) is inserted. The fluid injection is repeated after a short interval and withdrawal of the fluid already inserted, but a very small increase in amount is permitted. This is repeated three or four times with gradually increasing quantities of fluid. It is found that the patient can tolerate slight increases. The treatment is carried on over a period of a week or ten days, until a quantity of fluid amounting to 10 ounces can be retained by the patient. The fluid injected is boracic lotion at a temperature of 100° F.

The essential points of the treatment are: (1) The passage of a clean catheter; (2) the injection in gradually increasing quantities of a mild antiseptic at a little above body temperature and at a very low pressure. The bladder is thus trained to hold more fluid than it has previously done. All the patients upon whom I have tried this treatment, at whatever age, have very much improved in their power of retention, wherefore I have decided to put the method on record.—I am, Sir, yours faithfully,

A. R. THOMPSON,
Surgeon in Charge of the Genito-Urinary Department,
Guy's Hospital.

Wimpole-street, W., Oct. 8th, 1917.

QUININE THERAPY AND HYDROTHERAPY IN THE TREATMENT OF MALARIA

To the Editor of THE LANCET.

SIR,—Though the therapeutic value of quinine in severe malarial infections seems at the present time to be held in less confident esteem than formerly, the potency of this drug in affording relief from urgent symptoms in the considerable number of such cases which I was recently called upon to treat was a revelation to one who, like myself, has had no such previous experience, and as proficiency was gained in its use and administration urgent symptoms, especially those of cerebral type, no longer gave rise to the keen anxiety that they at first occasioned. On the other hand, as has been frequently noted by other observers, it was essentially in those persons in whom the disease became dormant, with only occasional exacerbations, that quinine proved to be less efficacious, which may have been due to the fact that these patients did not receive the massive dosage that was accorded to those in whom such urgent symptoms were present; for in order to procure good results it is, in my experience, essential that the drug be used with no sparing hand, and essential too, of course, that after administration it shall be absorbed.

Oral administration is not dependable. In the first place a large dose of quinine in mixture is very nasty, and such is the weakness of human nature, that patients will sometimes throw away a dose which they pretend to have taken. Secondly, when swallowed, it is quite uncertain at what rate it will enter the blood stream, a factor that must vary considerably in different individuals. In many patients an extraordinarily thick white furring of the tongue develops as soon as they begin to take quinine mixture, and in them it is unlikely that the process of absorption goes on satisfactorily or completely, whilst if exhibited in the form of compressed tablets the drug may never be absorbed at all. Thirdly, in addition to those effects that are desired, other undesirable effects are sometimes produced which may lower the patient's resistance towards other diseases, and especially, one would think, towards any intestinal infections that may be prevalent. From personal experience it is certain that an acute diarrhoea may be set up after taking no larger dose than 10 grains of the sulphate, for I could reckon on a night of colic with nine or ten watery motions after taking such a dose of quinine the previous evening for supposedly prophylactic purposes.

In severe cases, therefore, the drug should be given by injection. For this line of treatment the intravenous route is no doubt the most certainly efficient, but this method is also not unattended by disadvantages, and the results of intramuscular injection were so satisfactory that it seemed unwise to discard this latter in favour of any other method. 15 or 20 grains of the bihydrochloride were usually given at the commencement of treatment, which dose was repeated in the course of a few hours when coma or other urgent symptoms were present, and under continued energetic treatment even the apparently most desperate cases recovered For instance I had a man in my wards who lay in deep and stertorous coma for over 36 hours and who ultimately made a good recovery under large doses of quinine bi hydrochloride given in this way, 90 grains being administered in 24 hours This is a large dose and one that I personally never exceeded, but I have been shown cases in a foreign hospital where the maximum daily dose was 8 grammes (120 grains) given by intravenous injection, and the responsible medical officer in charge was himself a resident of a highly malarious country and possessed a wide experience in the treatment of the disease It would be interesting to know whether, when such doses have been constantly employed, anything other than good results have been obtained in severe cases of malaria

But by no means all cases of malaria are severe, and there are malarious countries where other means of treatment are also resorted to I have seen a peasant with a temperature of 104° F, who was suffering from both malaria and dysentery, standing to sluice his head and chest with cold water, although he was almost too weak to crawl out of bed at all, and others, too ill to rise, have called out daily for the same thing This belief in the efficacy of cold water is doubtless the result of experience and of the teaching of Priessnitz and his followers during the first half of last century, but it is not merely a local doctrine, for at the time that I found these peasants applying this line of treatment for themselves it was interesting to read in THE LANCET (1916) reports of successful hydrotherapeutic measures in the treatment of malaria in Switzerland Possibly it is precisely those cases with latent infections, in which, as already stated, quinine alone gives such disappointing results, that derive benefit from treatment by baths of various kinds If hydrotherapy has any influence at all, and there *must* be few who would deny that it has, it is surely to be expected that this would be demonstrated in just such a condition, in which liver, spleen, and other internal organs form the resting place for the infecting organism, which is ready to reassert itself whenever general conditions may be favourable for it to do so

For such a line of treatment, and especially at the present time, it may fairly be claimed that Torquay is peculiarly adapted, both by reason of its distinctive situation and on account of the thoroughly complete and up to-date bathing establishment that has lately been installed by the authorities, in which all baths and *douches*—hot and cold, local and general—can be administered with either salt water or with the exceptionally soft water from Dartmoor

I am, Sir, yours faithfully,
A E CARVER,
Late temporary Lieutenant R A M C

Torquay Oct 16th 1917

THE ANNUAL MEETING OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

To the Editor of THE LANCET

SIR,—The Society of Members of the Royal College of Surgeons of England addressed a letter to the Council of the Royal College of Surgeons of England respectfully suggesting that, in view of the present great pressure on the time and money of medical men at home, and the absence of so many of our members abroad on His Majesty's service, the annual meeting of Fellows and Members at the College should not be held this year the Society reserving its advocacy of the cause of the Members for future suitable occasions This suggestion was considered at a meeting of the Council of the College on Oct 11th, when it was decided to proceed with preparations for the annual meeting on the usual lines

We think that this decision is regrettable, as many Members will be unable to attend, while the expenses associated with the meeting might have been saved to the College funds

I am, Sir, yours faithfully,
SIDNEY C LAWRENCE,
Honorary Secretary Society of Members of the Royal College of Surgeons of England

Oct 14th 1917

SPIRAL FIELDS OF VISION AND NEURASTHENIA

To the Editor of THE LANCET

SIR,—Your review of Jones and Llewellyn's book on "Malingering," in your issue of August 4th, raises an interesting point regarding helicoid curves in the chapter on the eye contributed by me For while I have attributed spiral fields of vision to neurasthenia and not to hysteria, your reviewer believes that the converse is usually taught The helicoid appearance is, I think, universally considered to be due to the abnormally quickly induced fatigue typical of neurasthenic subjects I do not dispute the statement that helicoid fields were first observed in hysteria, but it is well recognised that neurasthenia may be associated with hysteria, and the peculiar field may, with plausibility, be referred to the neurasthenic element I think all authorities agree that if suggestibility be the salient feature of hysteria "fatigability" is the core of neurasthenia, and therefore a fatigue field is more characteristic of the latter syndrome

I am, Sir, yours faithfully,
W M BEAUMONT

Bath Oct 13th 1917

W J Smyth (late Surgeon Captain A.M S) to be temporary Major Hampshire Medical Volunteer Corps

S P Matthews to be temporary Lieutenant and Medical Officer 8th Battalion Sussex Volunteer Regiment

J G Miller (late Captain R.A.M C) to be temporary Second Lieutenant, 4th Battalion Northumberland Volunteer Regiment

R. A. Walter to be temporary Lieutenant and Medical Officer 3rd Battalion Kent Volunteer Regiment

G Stowell to be temporary Captain Lancashire Medical Volunteer Corps

E Harrison to be temporary Captain East Yorkshire Medical Volunteer Corp

Temp. Capt and Medical Officer J Lytle from 2nd Battalion Shropshire Volunteer Regiment, Temp Capt G Hollies from 1st Battalion Shropshire Volunteer Regiment and H O Woodhouse to be temporary Captains Shropshire Medical Volunteer Corps

Temp Cap and Medical Officer E. Quayle from 2nd Battalion Lancashire Volunteer Regiment, to be temporary Major Lancashire Medical Volunteer Corps

A. Linnell to be temporary Captain Northamptonshire Medical Volunteer Corps

W A. Warters to be temporary Lieutenant and Medical Officer 8th Battalion Derbyshire Volunteer Regiment

R F H. Newton to be temporary Lieutenant and Medical Officer 7th Sussex Volunteer Regiment.

E. W Archer (late Captain R.A.M C) to be temporary Captain and Medical Officer 2 3rd Battalion, East Riding Volunteer Regiment

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS

In the September number of this journal Mr R E Savage protozoologist attached to the Royal Army Medical Corps publishes a report on the treatment of 59 cases of *Entamœba histolytica* infection to which Captain J R. Young contributes some clinical remarks Most of the cases dealt with acquired their infection in Mesopotamia, Salonika, or Egypt but some had their first attack on Gallipoli in the winter of 1915 Thirty seven of the cases were cyst carriers while 22 were acute cases The results of five different courses of treatment with emetine emetine with pulv ipecacuanhæ, and emetine bismuth iodide are described A joint paper by Captain T J Mackie and Captain H G Wiltshire discusses the diagnostic interpretation of the agglutination test in typhoid and paratyphoid infection occurring among typhoid vaccinated troops and Mr H. M Woodcock D Sc. of the Lister Institute of Preventive Medicine gives the result of some protozoological experiences during the summer and autumn of 1916. Other articles are the Intravenous Administration of Quinine Bihydrochloride in Malaria and a Remark upon the Form of the Parasite Responsible for Relapses (War Office Investigations) by Lieutenant-Colonel S P James I.M S., and Methods Employed in the X Ray Department of a Military Hospital with a Few Notes on One or Two Cases of Interest and on the Treatment of Trench Foot Adopted There by Dr Russell J Reynolds Colonel R. H. Firth again reverts to his enjoyable Some Musings of an Idle Man."

URBAN VITAL STATISTICS

(Week ended Oct 13th 1917)

English and Welsh Towns —In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 17 000 000 persons the annual rate of mortality was 11 8 against 10·8 and 11 1 per 1000 in the two preceding weeks In London, with a population exceeding 4 000 000 persons the death rate was 12·0 or 0·5 per 1000 above that recorded in the previous week among the remaining towns the rates ranged from 3·6 in Acton 6·2 in Edmonton and 6·4 in Rochdale to 19·0 in Cambridge 19·9 in Middlesbrough and 21·9 in Stockton-on Tees. The principal epidemic diseases caused 381 deaths, which corresponded to an annual rate of 1·2 per 1000, and included 243 from infantile diarrhœa, 54 from diphtheria, 34 from whooping-cough 30 from measles 14 from enteric fever and 6 from scarlet fever The deaths from diarrhœa, which had been 344 267 and 278 in the three preceding weeks fell to 243 last week, and included 48 in London 16 in Sheffield 16 in Hull and 13 in Middlesbrough The 924 cases of scarlet fever and 1271 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were respectively 71 and 105 above the numbers remaining at the end of the previous week. Of the deaths from all causes in the 96 towns 120 resulted from violence The causes of 37 deaths were uncertified, of which 11 were registered in Birmingham and 3 in Darlington

Scotch Towns —In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2.500 000 persons the annual rate of mortality was 11·8 against 11·9 and 10 7 in the two preceding weeks. The 250 deaths in Glasgow corresponded to an annual rate of 11 7 per 1000 and included 10 from infantile diarrhœa, 7 from measles 7 from whooping-cough 3 from diphtheria, and 2 from scarlet fever The 67 deaths in Edinburgh were equal to a rate of 10·5 per 1000 and included 2 from diphtheria, 2 from infantile diarrhœa, and 1 from measles

Irish Towns —The 121 deaths in Dublin corresponded to an annual rate of 15·8 per 1000 or 4 3 above that recorded in the previous week and included 9 from infantile diarrhœa, 3 from diphtheria and 1 each from enteric fever and measles. The 87 deaths in Belfast were equal to a rate of 11 5 per 1000 and included 5 from infantile diarrhœa, 1 from enteric fever and 1 from diphtheria.

ROYAL MEDICAL BENEVOLENT FUND GUILD —The Guild has undertaken to administer a fund raised by the friends of the late Mrs John Phillips as a memorial to her work in aiding necessitous families of the medical profession A sum exceeding £500 has already been raised for an exhibition, and further subscriptions may be sent to the honorary treasurer, Mrs Muir "Yellow Wood" Weybridge A sum of £563 has also been allocated to the Guild by the friends and patients of the late Dr L Vernon Jones The annual income of both funds will be used for the education of children of those who are beneficiaries of the Benevolent Fund

The War.

THE CASUALTY LIST

THE following names of medical officers appear among the casualties announced since our last issue —

Killed

Temp Capt W T Chaning Pearce R.A M C, attached Liverpool Regiment, was educated at Cambridge and at Guy's Hospital London, and qualified in 1911 He held appointments at Guy's at the London Hospital, and at the Croydon General Hospital, and was in practice at Ramsgate before joining up

Capt K. T Limbery, R A.M.C, was a student at St Thomas's Hospital, London, and qualified at the beginning of 1916 He joined up shortly afterwards

Capt W D Reid, M C, R.A.M C, attached Manchester Regiment qualified at Edinburgh in 1910 The award of the M C was recorded in THE LANCET of March 10th, 1917, p 392

Capt N H W Saw, M C, R A M C, attached Worcestershire Regiment, was a student at Guy's Hospital, London, and qualified early in 1915, joining up shortly afterwards The award of the M C was recorded in THE LANCET of Sept 30th, 1916, p 621

Capt J H C Gatchell, R.A.M C, attached Royal Sussex Regiment, qualified at Dublin in 1912, and was in practice at Dunnamanagh, co Tyrone, prior to joining the R A.M C

Capt A. G Whitehorne Cole, R A.M C, was a student at St Mary's Hospital, London, and qualified in 1906 He held appointments at the Cancer Hospital and at St Mark's Hospital, London, and contributed several papers to medical literature He was in practice in New Cavendish street, London, before joining the R A.M C

Died of Wounds

Capt J J P Charles, R A.M C, attached Herts Regt, qualified at Edinburgh in 1909, and held appointments at the London Lock Hospital and at the Norfolk and Norwich Hospital He was in practice at Swanage before joining the R.A M C in August 1914

Capt L Oldershaw R A M C, attached Manchester Regiment was educated at Liverpool University and qualified in 1915, joining up shortly afterwards

Wounded

Lieut E H R Altounyan R A.M C attd London Rifles
Capt W McM Chesney M C, R A.M C
Capt A. Morris R.A.M C
Capt S J Simpson R.A M C
Capt W F Wilson, M C, R A M C, attd Royal Fusiliers
Lieut G S Lawrence R A.M C
Staff-Surgeon E L Atkinson, R N
Capt A. R Grant, R A.M C
Capt W McConnell, R.A.M C, attached Royal Fusiliers
Major J S Y Rogers R A M C
Lieut R C Rogers, R A.M C, attached R G A
Capt A. E Mackenzie, R A.M C, attached Royal West Surrey Regiment
Capt W F Young, R.A M C
Capt T B Brandon, R A M C
Capt F E Johnson, R A.M C
Capt F P Grove, R A M C, attd Royal Welsh Fusiliers

CASUALTIES AMONG THE SONS OF MEDICAL MEN

The following additional casualties among the sons of medical men are reported —

Brigadier General D E Cayley, C M G, wounded, son of the late Deputy Surgeon General H. Cayley, C M G

Temp Capt W T Chaning Pearce, R.A.M C, killed in action third son of Dr J Chaning Pearce, of Ramsgate

Capt H S Chalmers, Royal Field Artillery, died of wounds, second son of Dr A. K Chalmers of Glasgow

Capt L A. L Fink, M C, Bedfordshire Regiment, killed in action son of Major G H Fink, I M S (ret), of Finchley, London

Second Lieut H W Fleming, Bedfordshire Regiment killed in action, second son of the late Dr A. J Fleming, of Hampstead London

Capt J J P Charles, R A.M C died of wounds son of the late Professor Charles of Queen's University, Cork

Second Lieut D Heald, Rifle Brigade died of wounds, only surviving son of Dr H Heald of Ormskirk

Second Lieut S W Wayte, M C Royal Field Artillery died of wounds, younger son of Dr J Wayte, of Croydon

Capt A. A Clarke, M C Leicestershire Regiment killed in action only son of the late Dr A. Clarke, of Morley, Yorks

Second Lieut T G de Denne Devon Regiment killed in action, youngest son of Dr T V de Denne, of Sidmouth, Devon

Capt B W Conway, Manchester Regiment, killed in action, eldest son of Dr B W Conway, of Longsight, Manchester

Second Lieut J M Blake Devon Regt , killed in action son of the late Dr M D Blake, of Grantchester, Cambridge

MINISTRY OF NATIONAL SERVICE ITS MEDICAL ORGANISATION

The details of the organisation of the medical department of the Ministry of National Service have now been made public, and follow exactly upon the lines laid down by Sir Auckland Geddes in his recent speech at Nottingham which we published last week The Chief Commissioner of Medical Services with direct responsibility to the Minister is Dr James Galloway, whose duties are to organise and administer the medical service of the Ministry

Regions and Medical Commissioners

The regions into which the country has been divided for the purpose of making a medical survey of the male population of military age are as follows —

1 *Northern*, comprising Northumberland, Durham, Cumberland, Westmorland

2 *North Western*, comprising Lancashire and Cheshire Commissioner Dr G Redmayne Murray

3 *Yorks and East Midland*, comprising Yorkshire, Lincolnshire, Nottingham, Derby, Leicester Northampton, Rutland Commissioner Dr T Wardrop Griffith

4 *West Midland*, comprising Stafford, Warwick Worcester, Hereford, Shropshire Commissioner Colonel W H Bull

5 *Wales* Commissioner Dr W Bickerton Edwards

6 *South Western*, comprising Gloucester, Wilts, Somerset, Dorset, Devonshire, Cornwall Commissioner Sir James Porter

7 *East Anglia*, comprising Norfolk, Suffolk, Essex, Cambridge, Huntingdon, Bedford, Bucks, Oxford, Berks, Herts Commissioner Dr W.-Hale White

8 *South Eastern*, comprising Kent, Sussex, Hants, Surrey Commissioner Sir Charles Bedford

9 *London* Commissioner Colonel C R Tyrrell

10 *Scotland* Commissioner Dr Norman Walker

The Medical Boards

One or more medical boards will be established in each recruiting area into which the regions are divided The number of these boards is to be about one hundred, and the following places have been mentioned —

London Region —North London West London, South London, East London, Woolwich, Wandsworth, Wood Green, Hounslow, Holloway, White City, Camberwell, Stratford, Croydon

West Midland Region —Stoke-on Trent, Birmingham, Worcester, Hereford, Wolverhampton, Shrewsbury, Warwick, Lichfield (Stafford)

South Eastern Region —Brighton, Canterbury, Guildford, Maidstone Southampton

South Western Region —Plymouth, Bristol City Gloucester, Dorchester, Exeter, Taunton, Trowbridge Truro

East Anglian Region —Chelmsford, Oxford, Cambridge, Bedford, Huntingdon, Norwich, Ipswich, Aylesbury, Hertford Reading

Northern Region —Sunderland, Middlesbrough, Newcastle, Carlisle

North Western Region —Manchester, Lancaster, Ashton under Lyne, Warrington, Liverpool, Bury, Preston, Blackburn Chester

Yorks and East Midland Region —Derby, Leicester, Sheffield, Pontefract, Bradford, Northallerton, Hull, Nottingham, Lincoln, Leeds, Barnsley, York, Halifax, Northampton, Oakham

Scottish Region —Glasgow, Dundee, Ayr, Perth Galashiels Aberdeen, Edinburgh, Hamilton, Glencorse Nairn, Stirling, Inverness

Welsh Region —Cardiff, Wrexham, Newport, Carmarthen, Brecon

The new medical boards which come into being on Nov 1st will each consist of four local practitioners selected by the advisory board on the recommendation of the Statutory Medical War Committees from names furnished to them by the Local Medical War Committees Medical men who wish to serve are invited to communicate with their local committee or in the London district direct with the Central Committee A roster will be chosen of at least double the number of practitioners necessary to compose a board

Special Opinions and Appeals

In cases presenting difficulty, such as those of suspected tuberculosis, heart disease, and unusual defects of vision, the presidents of medical boards will be empowered to obtain the opinions of specialists, and it is hoped that the staffs of general and special hospitals throughout the country may be able to render assistance in giving special opinions In the case of appeals against the result of medical examination the exact mechanism will now be as follows Three medical assessors, appointed by the Local Government Board will be attached to the appeal tribunals Should the appeal tribunal on hearing a case decide that a medical re examination is desirable, they will forward all the papers bearing on the case to the medical assessors, who will re examine the man The decision of the medical assessors will be final as regards the man's physical condition and gradation

The New Gradations

We have already defined in general terms the four groups of the new gradation, and can now give them more precisely as follows —

Grade I to consist of men who attain the normal standard of health and strength and are capable of the physical exertion suitable to their age

Grade II includes those who do not attain the standard of Grade I from various causes, such as deficient physical development or slight defects, but are yet fit for work of a less strenuous kind Most of these are capable of improvement by training Grade I corresponds to Class A or General Service of the late classification and Grade II to classes BI and CI —i e , to garrison duty abroad and at home

Grade III includes those who from any cause are not suitable to undergo military training as combatants although they may be quite fit for one of the auxiliary Services connected with the Army, and fit also for the work on which they are already employed or its equivalent

Grade IV includes all those who are unfit both for military service and any work of national importance

Other Functions of the Medical Department

Another serious function of the medical department of the Ministry will be to consider the supply of students in the medical schools in its bearing upon the future strength of the medical profession and to determine the necessity for bringing back from the Services men who are now serving in a non medical capacity We noted last week the personnel of the medical advisory board which will keep in close touch with medical opinion and in coöperation with existing organisations To the names there given should now be added that of Mr Percy Edwards, of Liverpool

Manual of Medical Standards

In the manual of general directions for the guidance of medical boards, which is now nearly ready, a scheme is outlined by which every man is seen by each member of the medical board at some stage of his examination, while his final gradation is settled by the consensus of opinion of the members and president This procedure will meet the complaints which have been made in the past that the president omits to consult the opinion of his board or over rules their decision The scheme continues —

When a man wishes to appeal against the gradation of the medical board he must lodge his appeal within five clear days of his examination, and will forward in duplicate any medical certificates he may wish to place before the tribunal If the appeal tribunal after hearing the case decides that the claim is one in which they think medical re examination is desirable, they will forward all the documents bearing on the case to the medical assessors appointed by the Local Government Board, accompanied by the appeal tribunal's recommendation that the man should be re examined The medical assessors will inform the man of the date on which he should present himself for re-examination, giving at least three clear days' notice A representative of the medical board which graded the man will be present at the meeting of the medical assessors of the appeal tribunal, if they desire it, in order to supply any information which may be required The medical assessors will communicate their decision to the chairman of the appeal tribunal, who will then make arrangements for the final adjustment of the man's case The medical assessors will also give the man a card (known as 3291) showing the grade in which they have placed him

Questions of principle in the gradation of men suffering from certain disabilities which cannot be decided by reference to the manual may be stated in writing by the board or assessors concerned and referred to the Ministry, when the matter will be placed before the advisory board of the medical department for an opinion. It will also be within the power of the Ministry to refer such questions to medical men competent to decide on the particular subject

ITALY AND THE WAR

We have received from our Correspondent at the Italian front the following medical notes —

British Hospital at the Italian Front —During his recent tour of the Italian front Lord Derby paid a visit to the British Military Hospital, which, in the hands of the Italian Army engineers, is arising with marvellous rapidity in the orchard of a farmhouse in a small Austrian village In the original house are the offices, small wards and wards for sick officers, the main accommodation is in long two-storey buildings of brick and cement, each block containing two wards one above the other The operating theatre with anæsthetising and sterilising rooms, forms a separate building, and there are also a cook house, a laundry, and a bath house, with shower baths and small bathrooms The British Red Cross Society, which has rendered invaluable help in the equipment of the hospital, was represented on the occasion of this visit by its Chief Commissioner for Italy, Lord Monson The Secretary of State for War made a round of the wards and expressed his complete satisfaction with all the arrangements

The Medical Services at the Front.—The number of convenient buildings and the excellent state of the roads have been big factors in the medical arrangements for the Army on this front Field hospitals are established everywhere in fine buildings, and everywhere communications are easy by good roads with plenty of motor transport Such conditions would seem ideal, and should lead to ideal results if the organisation allowed But at present there is far too much evacuating from one field hospital to another a few miles further back, with the result that during an offensive all are overcrowded and overworked with the constant stream of wounded, and the latter are apt to get inefficient attention It is often several days with a brief stay in as many hospitals, before the originally lightly wounded case at last arrives where his wound can be definitely dressed By now the simple injury may have become seriously infected an unnecessarily long stay in hospital is ensured and a corresponding economic loss to the country It should not be difficult with the amount of motor transport at command to send all but the severely wounded direct from the ambulances to the base hospital, a journey by road of from two to three hours at most, and so leave the advanced hospitals free to deal with the serious cases and keep them as long as needful Distinguished civilian surgeons have been instant in urging this reform but at present without success Wounds of the abdomen thorax, and cranial cavity, however are treated in special advanced surgical hospitals under the charge of skilled surgeons and here the system seems wonderfully perfect under war conditions The treatment of sickness is very well organised, especially as regards infective maladies, under which category is included diarrhœa. These cases are all sent to special hospitals with ample accommodation in the war zone. The protection of the rest of the country is strictly cared for All sick are sent to isolation hospitals where they are bacteriologically certified free from infection before they can leave the zone of war for their homes or territorial hospitals With the excellent state of health prevailing this year among the troops at the front this seems almost an unnecessary precaution, yet it guarantees the country from epidemic disease and is rendered the more advisable on account of the frequency of disease among the Austrian prisoners, who are all disinfected and bacteriologically examined in the prisoners' concentration camps before being sent to the interior Over 60 bacteriological laboratories are thus employed in the war area.

Trachoma and Tuberculosis —The spread of these diseases is seriously occupying the attention of the profession of this country Before the war men suffering from trachoma and its after effects were not taken for military service and rejection for this cause alone reached the number of 31 per mille in Sicily After the outbreak of war, however, this regulation was no longer enforced, and very shortly it was discovered that the disease was spreading seriously in the Army An order was at once issued that all such cases should be sent to their homes, with two deplorable results—a great spread of the contagion wilfully among the troops and an involuntary spread among the civilian population With regard to tuberculosis, here, as probably elsewhere, there is a want of unity in the ideas which govern the medical officers in accepting or rejecting possible cases Professor Edoardo Maragliano, who speaks with acknowledged authority upon the disease, draws attention to this confusion in an article in the *Giornale di Medicina Militare*, and declares that the sole question before the examining medical officer is whether the man is infected with tuberculosis or not If the answer is Yes he must be rejected for the Army, however good his health may seem, for no doctor can guarantee that he has sufficient resistance for the successful endurance of a soldier's life, either within or behind the zone of war He should not be classified as fit for certain military duties Both the nation and the Government desire to have no tuberculous subject in the Army, the doctor who rigorously rejects them is rendering a service to the Army to day and to the country to-morrow

October 1917

MR FRANCIS DODD'S PORTRAITS —The leaders of our Navy and Army are being excellently drawn in colours by Mr Francis Dodd, the examples which have reached us being Sir Douglas Haig General Smuts, Admiral Sir John Jellicoe, and Admiral Beatty The reproductions of these portraits can be obtained from *Country Life* Tavistock street London, W C, at 2*s* 6*d* each They are on a large though not a uniform scale, and are mounted for framing with real good taste

LEAGUE OF MERCY WAR BAZAAR —As already announced the League of Mercy has organised a bazaar to be held at the Ritz Hotel on Wednesday and Thursday next in aid of the voluntary hospitals Princess Alice, Countess of Athlone, will open the bazaar on the first day and Princess Patricia of Connaught on the second The bazaar will be opened each day at 2 30 P M and the prices for the opening ceremonies will be 10*s* and 5*s* respectively After the opening ceremonies 5*s* will be charged on the first day and 2*s* 6*d* on the second and from 5 to 7 P M on the second day 1*s* Tickets may be obtained at the doors or from Mr W and Miss Andrews, honorary organising secretaries, 5 Belsize park, N W 3 and Mr R M F Robertson, 70, Queen Victoria street E C 4

PURE WHEATEN FLOUR FOR INVALIDS

THE following is the official Memorandum on permits for the use of pure wheaten flour for invalids issued by the Ministry of Food after consultation with the War Bread Medical Subcommittee of the Royal Society The Memorandum was required, as some misunderstanding appears to exist as to the granting of permits to use white flour, it is wise therefore, to indicate the procedure adopted in dealing with applications These are considered in the first instance by the scientific adviser to the Food Controller acting under the guidance of the War Bread Medical Subcommittee of the Royal Society After this first sitting of applications doubtful cases are referred to certain members of the subcommittee who have agreed to act as referees or they are laid before the whole subcommittee It should be understood that applications are becoming so numerous and the necessity for economising wheat so imperative that it is not possible to accede to all the requests sent in The committee is of opinion that in many cases no substantial grounds exist for the applications which appear to be made merely to satisfy some whim of the patient and not because the Government regulation flour has been found to be deleterious Speaking generally, it may be said that unless some affection of the digestive organs which in the opinion of the War Bread Medical Subcommittee justifies the use of pure wheaten flour is present, an application cannot be granted

1 *Acute affections of the stomach* (acute gastric catarrh, ulcer in its acute stages, &c) —In these cases the use of any form of bread whilst the disease is at its height is probably inadmissible During the convalescent stages the prescription of pure wheaten flour for a limited period may be

permissible if rusks and breakfast biscuits or ordinary bread boiled and sieved, or bread jelly, does not meet the case

2 *Chronic affections of the stomach* —In chronic functional disorders of the stomach (which make up the majority of cases of chronic dyspepsia) the use of pure wheaten flour can rarely be allowed for the reason that such cases are so numerous and so protracted in their course that it would be impossible to meet the demand without seriously depleting the wheat-supply of the rest of the population The use of the present bread, well toasted and thoroughly chewed, or of biscuits and rusks, should be recommended

In chronic *organic disease* of the stomach (carcinoma and chronic ulcer) white flour may sometimes be advisable if the patient is able to take bread at all

3 *Acute affections of the intestine* (acute diarrhœa, enteritis, colitis, ulcerative conditions, &c) —In these cases the same remark applies as in acute affections of the stomach

4 *Chronic intestinal affections* (chronic diarrhœa, chronic colitis, malignant disease, &c) —In some of these the use of white flour may be desirable, but evidence would be required to show that ordinary bread, toasted and thoroughly chewed, and the use of other measures have failed to relieve the symptoms

Cases of disease of the nervous, circulatory, or respiratory systems, or of the urinary organs or skin, or such general conditions as anæmia and diabetes, can rarely be considered suitable for grants

As regards tuberculosis, there is no evidence that the present bread is injurious Inquiries have been made from the principal sanatoria for the treatment of this disease, and in the great majority of cases the medical superintendents support the above opinion No institution for the treatment of this disease is receiving grants of pure wheaten flour

The conclusion of the subcommittee is that there are very few conditions, in the opinion of the War Bread Medical Subcommittee, in which the use of pure wheaten flour is *essential* The subcommittee is well aware of the difficult position in which the medical practitioners are placed, but it is necessary to conserve the wheat-supplies of the country, and every means of doing this must be adopted, and, if need be, enforced Refusal to give a permit does not imply that the medical certificate has been disregarded, but merely that the need of other applicants appeared to be more urgent

Above all, it is important that no discrimination be made between rich and poor in recommending these grants Nothing is easier to arouse or more difficult to allay than a suspicion that the poor are denied what the rich find no difficulty in obtaining

Regarding the war bread as an ordinary article of diet, the Memorandum states as follows —

Under war conditions when variety in foods is limited the bread made from G R flour is probably a more wholesome article of diet than that made from fine wheaten flour in pre war times The flour contains more lime salts than fine wheaten flour, and presumably is therefore more suitable for growing children It contains a greater variety of proteins which it is important to have, especially if bread enters largely into the dietary It contains more "germ," which adds to the proteins and increases the fat It also contains more of the class of substances known as vitamines, about which our knowledge is far from complete, but it is known that a deficiency of these profoundly impairs nutrition The bread requires to be thoroughly masticated, but if chewed well, or eaten as toast which necessitates chewing, or, finally (in the case of invalids), if it be used as indicated in the preceding paragraph, there are very few people with whom it could disagree

---

AN X RAY INSTALLATION AT WORTHING —The Worthing Education Committee has decided to purchase and instal at the school clinic an X ray apparatus mainly for the purpose of the treatment of ringworm No fewer than 40 cases of ringworm, it was stated at the meeting of the committee, are now excluded from the schools of the town

SERVICE FOR DOCTORS AND NURSES —The Vicar of Brighton (the Rev Prebendary Dormer Pierce) is continuing the custom of holding an annual service for doctors nurses, and V A D workers, and this was held in the Parish Church at Brighton on Sunday evening last, a large number of medical men, nurses, and ambulance workers attending The vicar pleaded for close coöperation between priest and doctor The medical profession was a teacher of benevolence and human pity Doctors nurses, and V A D workers were all engaged in the same ministry —the revelation of God as the God of health

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND —At the quarterly examination in Practical Pharmacy, held on Oct 11th and 12th, the following candidates were successful —

Abraham Abelson University College Hospital Robert Geoffrey Addenbrooke Birmingham University Esawy Ahmed London Hospital John Binford Barnett, Birmingham University Jules Samuel Boruchowitz Brussels and University College Hospital Gerald Arthur Augustine Bradnock Guy s Hospital Geoffrey Wright Dando Birmingham University Douglas Alexander Dyer St George s Hospital Harland Bernard Easten, St Mary's Hospital Frank Edward Edwards Manchester University Francis Malcolm Timothy Flintan Middlesex Hospital Lydia Susan Fuller Maitland and Irene Mary Golding London School of Medicine for Women Christopher Frank Good London Hospital Ernest Alphonse Hardy Charing Cross Hospital Geoffrey Gordon Havers Cambridge University and St Bartholomew's Hospital Janet Hughes, King s College Reginald Jenner Clarke, London Hospital John Kendall Guy s Hospital Francis Wharton Lemarchand St. Bartholomew s Hospital Horace Sharman Le Marquand St. Thomas s Hospital; Elizabeth Esther McCulloch Liverpool University William Dundas Macrae London Hospital Guy Meadows Guy's Hospital Margaret Ombler Meek Charing Cross Hospital Henry Marie Alphonse Menage St Bartholomew's Hospital Edward Nisim Bombay University and University College Hospital Geoffrey Noott Guy s Hospital Ruth Emerita Pilgrim and Norah Katharine Priestley London School of Medicine for Women Henry Christoffers Powell Charing Cross Hospital Hubert Llewellyn Pridham, St Bartholomew s Hospital Owen Alfred Llewellyn Roberts St. Mary s Hospital Arthur Twynham Spoor Cambridge University and St Thomas s Hospital Edward Algernon Weaver Birmingham University; and Julius Maurice Winnett London Hospital

ROYAL COLLEGE OF SURGEONS OF ENGLAND —A quarterly meeting of the Council was held on Oct 11th, Sir George Makins the President, being in the chair The President reported the death on July 27th of Dr Theodor Kocher, of Berne, an Honorary Fellow of the College, and stated that he had written to the widow to express the sympathy and condolence of the Council A letter was read from Surgeon General Sir Alfred H Keogh, G C.B, expressing his great appreciation of having had the dignity of the Honorary Fellowship of the College conferred on him by the Council The President reported that Surgeon General Sir Alfred Keogh had attended that day to receive the Diploma of Honorary Fellowship and to sign the Roll, and that, after this ceremony, Sir Alfred Keogh had declared open the exhibition of War Office specimens of military injuries temporarily installed in Rooms 1 and 2 of the Museum Three months' leave of absence was granted to the President on Government work Leave of absence was granted to Sir Berkeley Moynihan from the October and November meetings of the Council during his absence abroad on Government duties The best thanks of the Council were given to Mr Alban Doran for his valuable services in continuing to arrange and catalogue the collection of surgical instruments in the Museum The President reported that in response to the request of the Museum Committee he had authorised the temporary installation of the electric light in Rooms 1 and 2 of the Museum for illuminating the exhibition on dark days The draft report of the Council to be presented to the annual meeting of Fellows and Members was approved Mr Bilton Pollard was re-elected a member of the Committee of Management Sir George Makins was appointed a member of the Court of the University of Liverpool for three years from Jan 1st next The President reported that he had granted the use of the theatre for five lectures in October to be delivered by Mr Twort, superintendent of the Brown Animal Sanatory Institution The President reported that he had given permission for the practical examination in physical anthropology, forming part of the B Sc London honours examination in human anatomy and morphology for internal students to be held at the College on Nov 1st There are three candidates

ROYAL INSTITUTE OF PUBLIC HEALTH —A course of lectures and discussions on Public Health Problems Under War and After War Conditions is to be held in the lecture hall of the Institute (37 Russell square, London, W C 1) on Wednesdays in October, November and December, at 4 P M as follows —Oct 31st Health Problems and a State Ministry of Health, by Major Waldorf Astor, M P Nov 7th Woman's Health and Work in War Time by Mrs Ogilvie Gordon, D Sc Nov 14th The Problem of the Disabled, by Sir Robert Jones Nov 21st Red Cross Work Under War Conditions, by Sir Arthur Stanley Dec 5th Women Workers and the Health of the Nation by Miss A M Anderson Dec 12th Some Aspects of the Tuberculosis Problem—Treatment and Training of Surgical Tuberculosis Cases by Mr Henry J Gauvain M R C S Dec 19th Public Health and Alcoholism in Women, by

Lord D'Abernon The Harben Lectures on the Treatment of Infected Wounds will be given by Dr Alexis Carrel, of the Rockefeller Institute, New York, on Nov 26th, 27th and 28th, at 4 P M The principal of the Institute will be in the chair Medical officers of health, medical practitioners, sanitarians, and others engaged in public health and national services are invited to attend No tickets of admission are required Further particulars may be obtained from the Secretary, 37, Russell square

THE MINISTRY OF HEALTH —The Lord Mayor is taking the chair at a National Conference of Sanitary Authorities, convened by the National Association for the Prevention of Infant Mortality and for the Welfare of Infancy to be held at the Mansion House on Monday, Oct 29th, from 11 A.M , to consider the proposed Ministry of Public Health, with special reference to safeguarding the interests of motherhood and infancy in connexion therewith Tickets may be obtained free of charge on application to the Secretary, 4, Tavistock square, W C 1

CENTRAL MIDWIVES BOARD —A special meeting of the Central Midwives Board was held at Queen Anne's Gate Buildings, Westminster on Oct 10th, with Sir Francis H Champneys in the chair Certain midwives were struck off the Roll, the following charges, amongst others, having been brought forward —

Being in attendance at a confinement the midwife neglected to cleanse the child's eyelids at birth as required by Rule E 16 in contravention of Rule E 12 she neglected to provide for the cleanliness and comfort of patients during her attendance and failed to give adequate directions to the person entrusted with the duty of washing them The midwife did not enter her records of pulse and temperature in a notebook or on a chart carefully preserved as required by Rule E 14 and did not keep her register of cases as required by Rule E 24 she neglected to disinfect her hands and forearms before touching the generative organs of the patient, as required by Rule E 4 and neglected to wash the patient's external parts with soap and water and to swab them with an efficient antiseptic solution on the occasions required by Rule E 8 and employed for washing the patient the same water as that in which the child had been washed. The midwife not being scrupulously clean in every way as required by Rule E 2, neglecting to take with her to a confinement the appliances and antiseptics required by Rule E 3 and declining to afford reasonable facilities to the duly appointed officer of the local supervising authority for the purpose of investigating her mode of practice, contrary to the provisions of Rule E 25 A child suffering from inflammation of and discharge from the eyes and continuing so to suffer during her attendance, the midwife did not explain that the case was one in which the attendance of a registered medical practitioner was required as provided by Rule E.21 (5) having continued in attendance on the patient after the tenth day she neglected to note the fact in her register with the explanation of the reason therefor as required by Rule E 12.

MEDICAL SOCIETY OF LONDON —The next meeting of this society will be held on Monday, Oct 22nd, at 8 30 P M , at 11, Chandos street, Cavendish square, W , when Mr Muirhead Little and Major R. C Elmslie, R A M C (T) will introduce a discussion on Modern Artificial Limbs and their Influence upon Methods of Amputation There will be a practical demonstration with patients and appliances Colonial and American medical men on active service will be welcomed at the meeting

MIDDLESEX HOSPITAL MEDICAL SCHOOL —The following scholarships medal, and prizes were awarded during the session 1916-17 —Entrance Scholarships First, H B Shaw, second, E B Dancy third, J Whitby Broderip Scholarship, R E S Webb Lyell Medal and Scholarship and Freeman Scholarship, S C Shaw Hetley Clinical Prize, R E S Webb Second year's Exhibition, O S Hillman

ROYAL SANITARY INSTITUTE —A meeting under the auspices of this institute will take place in the council chamber of the Town Hall Newcastle-on Tyne, on Nov 9th at 7 P M , when general discussions on Standards of Meat Inspection under War time and other Conditions and Structure in Municipal Housing will be respectively opened by Mr Thomas Parker veterinary officer and inspector of provisions for Newcastle-on Tyne, and Mr John H Mole, sanitary inspector and surveyor for the Chester le Street rural district council Dr Philip Boobbyer will preside On Nov 10th a luncheon will be given by the sanitary committee of the corporation, and a visit will be afterwards paid to the Belgian village, Elizabethville when the planning and structure of the temporary and semi permanent types of the dwellings will be inspected Applications for tickets should be made to the honorary local secretary Dr Harold Kerr Health Department Town Hall Newcastle-on Tyne , or to the Secretary of the Institute 90 Buckingham Palace road, London, S W , not later than Nov 2nd

AT the quarterly meeting of the directors of the Naval Medical Compassionate Fund held on Oct 16th Surgeon General W H Norman in the chair the sum of £20 was distributed among the several applicants

Notes, Short Comments, and Answers to Correspondents.

PUBLIC HEALTH IN EAST AFRICA.

HIS Excellency H Conway Belfield, C M G, Governor, has forwarded to the Colonial Office a report on the East Africa Protectorate for the financial year 1915–16 It includes the following particulars respecting the health conditions of the various districts —

Coast Zone —The average health remained good throughout the year There were 7112 cases of malaria treated, with only 14 deaths There were 6 cases of blackwater fever and 1 patient, a European died 27 cases of cerebro-spinal meningitis occurred with 12 deaths There were 317 admissions for dysentery with 39 deaths 26 Europeans were treated for the disease of whom 1 died. 12 cases of enteric fever were treated of whom 9 were Europeans there were 5 deaths, 4 being Europeans No case of plague was reported and no infected rats were found 41 cases of beri beri with 1 death were noted at Mombasa Native Civil Hospital. 6 cases of small pox were discovered of whom 2 died. 436 cases of leprosy were reported from settlements at Mombasa, Malinda and Lamu

Mountainous Zone —The number of admissions for malaria was 5352, a large increase over the number admitted in 1914 Nairobi was responsible for the largest number of cases but every township appeared in the list Of 520 Europeans affected 2 died 9 cases of blackwater fever were treated 2 being Europeans 1 death occurred in a native case The virulence of cerebro-spinal meningitis appears *to be dying down* During 1915 there were 3 cases among Europeans and 78 among natives with 3 deaths An increase was noted in cases of dysentery, 1647 cases being admitted of whom 89 died 105 of the cases admitted were Europeans all of whom recovered In the previous year there were only 1471 admissions with 49 deaths the increase is attributed to the changed conditions produced by the war The admissions for enteric fever rose from 46 (10 deaths) in 1914 to 182 (19 deaths) in 1915 35 cases occurred amongst Europeans, of whom 3 died 347 cases of pneumonia were recorded with 62 deaths 13 of the cases with 2 deaths were Europeans

Kenya and Nyanza Provinces —4687 cases of malaria were treated showing a continued increase There were 3 European cases of blackwater fever with 1 death Only 1 case of trypanosomiasis came to light Cerebro-spinal meningitis is fairly prevalent throughout the Nyanza Province 27 cases were treated with 23 deaths Dysentery showed a notable increase and totalled including 2 Europeans 651 admissions, of whom 39 died Only 2 cases of enteric fever were recorded. Cases of plague have been numerous in Nyanza Province, but figures showing the number of cases in the native Reserves are unobtainable, 33 native cases were admitted to Kisumu Hospital, and of these 29 died There were 24 admissions of smal pox during 1915 of whom 2 died *An outbreak occurred in* Nyanza Province, near the Uganda border and spread to Kisumu 614 cases were treated in the North Kavirondo district as out-patients *up to* March 31st, *1916* and *148 deaths were recorded*

Desert Zone —1666 cases of malaria were admitted to treatment, and there was one European case of blackwater fever There were 9 cases of beri beri none being fatal Admissions for dysentery numbered only 107 as compared with 373 in the previous year

According to the Blue-book, just issued, of the Zanzibar Protectorate for the year 1916, the population of the island of Zanzibar is 114,069 and that of Pemba 83,130, the density of population is estimated at 175 per square mile in Zanzibar and 219 in Pemba The birth rate (births registered) for the year 1916 was 17 3, as against 19 7 per 1000 in 1915, the death rate is not stated Measures are being taken to ensure more accurate registration of births, and it is considered probable that when the registration of all births is secured it will be found that the births equal, or may even exceed, the deaths, contrary to opinions based on the figures now available

The islands of Zanzibar and Pemba were free from any severe epidemic of disease during the year and the health of the community was fair 28 deaths from *tuberculosis* and 16 deaths from malaria were so certified These figures are not comparable with those for previous years and although they do not accurately indicate the true prevalence of these diseases only 25 per cent. of all deaths being certified by qualified medical men they are the only figures available which are at all accurate Three deaths were certified from blackwater fever No case of plague was reported during the year but there were 18 cases of small pox of which 3 were fatal There were 8 cases all fatal of cerebro-spinal meningitis and 6 deaths from tetanus occurred The number of lepers in the two islands amounts probably to about 450 Of these 107 are segregated in one settlement in Zanzibar administered by the Roman Catholic Mission under the supervision of the medical officer of health and 185 in three settlements in Pemba while the remainder are at large

BACTERIOLOGICAL RESEARCH IN NEW ZEALAND

To the Editor of THE LANCET

SIR,—Could any of your readers give me any information as to the prospects for a bacteriologist in New Zealand next year or after the war? Could a living be made out of pathological and bacteriological work alone, or would it have to be part of general medical work? Any information or source from which information can be obtained will be thankfully received by,

Yours truly,
INQUIRER (1)

Oct 13th 1917

OCT 18TH DIES SANCTI LUCÆ

THAT St. Luke was a practising physician is now generally accepted. Baring-Gould, in his "Lives of the Saints," considers that he was a slave specially trained to act as family doctor to some patrician family in accordance with the custom of the time. Dr Clapton, in his "Life of Saint Luke" considers that St Luke went through a definite medical training and graduated at the University of Antioch. Miss Stawell in an illuminating paper which she read at the last International Medical Congress in London suggests that he was well acquainted with Virgil and influenced by Virgil's writings. Some have gone so far as to suggest that St. Luke and Virgil were the same person but this is out of the question. Virgil died B.C 19 and St Luke was not born until five years later

AN UNKNOWN SCULPTOR

To the Editor of THE LANCET

SIR,—In the new building of the University of Edinburgh, just outside the entrance to the Anatomical Museum, there stood in 1892 a Grecian statue of a discobolus (?) which, according to Sir William Turner, the then professor of anatomy, was about the most perfect statue showing the muscular development. Will any of your readers kindly let me know the full particulars as regards the sculptor, and where the original is to be seen now. I do not find it figured in any of the ordinary works on Grecian sculpture.—I am, Sir, yours faithfully

Sept 10th, 1917 D. A. T

A NEW FRACTURE SUSPENSION APPARATUS

Dr J. M. Barlet, medical officer in charge of the French Hospital, Shaftesbury Avenue, has called our attention to the fact that the apparatus for slinging fractured limbs exhibited at the McCaul Hospital for Officers and described in THE LANCET of Sept. 15th has been in use for a long time at the American Red Cross Hospital of Paris, and was described and figured by Dr J. Blake, médecin-chef and director of this hospital in the *Archives de Médecine et de Pharmacie Militaires*. We have seen a reprint of Dr Blake's article published by L. Fournier, Paris, in 1916, in which are illustrated precisely the apparatus shown to our representative at the McCaul Hospital. Dr Blake writes —

> Without wishing to detract from the reputation of Miss Gasetti who has done very good work over here, I must say that she has claimed originality for much apparatus which has not only been in use for a long time but which she first saw in the service for the surgeons under whom she was serving. Of course, the treatment of fractures by suspension and traction is not at all new and consequently no one can claim it as their special method, and I do not think for this reason that this particular treatment should be given my name any more than Miss Gasetti. All I have done is simply to standardise the method by which it can be carried out systematically and with the materials which can most easily be obtainable.

CUPRASE

To the Editor of THE LANCET

SIR,—I shall be much obliged if any of your readers can inform me as to the result of use of cuprase in treatment of cancer in England.—I am, Sir, yours faithfully

DOUBLE YELKED EGGS

To the Editor of THE LANCET

SIR,—In THE LANCET of Oct 6th a correspondent writes of an egg with two yelks. I have had this season from my poultry yard 30 double-yelked eggs of large size, necessitating the use of a wineglass (circumference 7 in.) as egg-cup

I am, Sir, yours faithfully,

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, *and when accompanied by blocks it is requested that the name of the author, and if possible of the article, should be written on the blocks to facilitate identification.*

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

Offices: 423, STRAND, LONDON, W.C. 2.

MANAGER'S NOTICES

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W C 2, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c, should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

The Harveian Oration:

HARVEY'S WORK CONSIDERED IN RELATION TO SCIENTIFIC KNOWLEDGE AND UNIVERSITY EDUCATION IN HIS TIME

Delivered before the Royal College of Physicians of London on Oct 18th, 1917,

BY ROBERT SAUNDBY, M D, F R C P, M Sc, LL D,

EX PROFESSOR OF MEDICINE, UNIVERSITY OF BIRMINGHAM; CONSULTING PHYSICIAN BIRMINGHAM GENERAL HOSPITAL.

MR. PRESIDENT, FELLOWS OF THE COLLEGE AND GENTLEMEN,—In the first place I have to thank you, Sir, for entrusting me with the most honourable duty of delivering the annual oration founded by our greatest associate, Dr William Harvey, the supreme glory of our College, whose memory we all cherish and whose work is universally regarded as the peculiar pride of English medicine In founding this oration he enjoined in the deed of gift that the orator *should exhort the Fellows of the College* to search out and study the secrets of nature by way of experiment, and for the honour of the profession to continue in mutual love and affection among themselves It was also his wish that on this occasion should be commemorated those benefactors of the College who by gifts or by their contributions to medical knowledge have forwarded the interests of this College in the course of the bygone year

RECOGNITION OF HARVEY'S WORK

Harvey's work has been justly regarded as remarkable by its great success in his own lifetime, and especially in his own country and among his colleagues in this College, where there appear to have been no discordant voices So far from it being true, as a recent British writer has ventured to say, that the only criticisms on his work were heard from his fellow countrymen, the very contrary is the truth, and, as Willis expressly says, the appearance of Harvey s book seems almost immediately to have attracted the attention of all the better intellects among the medical men of Europe The controversy on the circulation was carried on abroad rather than at home, for Harvey seems to have won over to his side all the men of his own country who by their education and acquirements might have been fitted to array themselves against him, and the first publication to deal with the question by one of Harvey's countrymen was that of Dr George Ent, who undertook to defend Harvey's teaching against the criticisms of Parisanus

A century had to elapse before the voice of criticism was heard from any British authority, and then it was the extremely able but somewhat quarrelsome anatomist Dr William Hunter, who sought to depreciate the work of Harvey by comparing it with the discovery of America by Columbus and the astronomical induction of Copernicus, disparaging Harvey's mental abilities on the ground of his failure to recognise the value of the discovery of the lacteals by Asellius, whose book was published about the same time as that of Harvey on the Circulation of the Blood (16?7) William Hunter's quarrel with his glorious brother John over the placental circulation does not show him in a very amiable or even an altogether honest light, and much as we may regret that so able an anatomist should have adopted this hypercritical attitude I think we may fairly say that his comments in no way succeeded in diminishing the glory of Harvey

CONTRIBUTIONS TO HARVEIAN LITERATURE.

Successive Harveian orators have so diligently explored the somewhat scanty literary remains that throw any light upon the life and doings of our illustrious fellow countryman that the College warmly appreciated the address by the late President Sir Thomas Barlow, who occupied this chair in October, 1916 and by his munificence had placed in the possession of the College certain documents, consisting of eight of Harvey s own letters written at the time when he accompanied the Earl of Arundel on an embassy to the Emperor Ferdinand Although these letters deal with only a short episode in the life of Harvey and throw no light whatever upon his physiological researches, they are exceedingly welcome as being contemporary accounts in his own handwriting, illustrating some at least of the difficulties that a traveller in those days met with even when forming part of the suite of a British Ambassador It is not often that a Fellow of this College enjoys the opportunity of making a benefaction which is so closely related to the personality of Harvey, but it is possible that in the much greater attention now paid to the State papers which were so long neglected, more may be found bearing upon the life of Harvey in his position at the Court of Charles I , where he undoubtedly enjoyed the favour and the personal friendship of the King

The College must acknowledge a valuable contribution to its Harveian literature in the publication of a memoir to recall the seventeenth century friendship of Finch and Baines, written by Dr Malloch, a Captain in the Canadian Army Medical Corps These two graduates of Cambridge in the seventeenth century went from Cambridge to France and thence to Padua, where the professor who lectured to them on anatomy was *Antonio* Molinetto Finch was a brother of Lord Nottingham, whose niece was the wife of Harvey, for whom he entertained the greatest veneration From Padua they went to Pisa where Finch was appointed professor of anatomy, his course of lectures including both morbid and comparative anatomy While there he examined a live torpedo (*T narce*) sent him by the Grand Duke of Tuscany He describes a "pricking sensation like that which comes when you suddenly put cold fingers to the fire," on touching the fish Later when it died he dissected it and his report is extant , it is to be issued shortly by the Historical MSS Commission edited by Mrs Lomas The friends returned to England soon after the Restoration, Baines being appointed professor of music at Gresham College, and both were unanimously elected Fellows of this College, partly no doubt on the ground of their relationship by marriage and friendship with the illustrious Harvey Soon after they received their degrees as Doctors of Physic at Cambridge and in the same month the King knighted Finch, the like honour being conferred on Baines 11 years later Finch returned to Italy and again taught anatomy at Pisa In 1665 he was appointed the King's resident at the Court of Tuscany and stayed there with Baines until the death of the Grand Duke in 1670 Finch was next sent to the Porte as English Ambassador and remained in Turkey till 1681 when Sir Thomas Baines died, and Finch brought the body home , he died shortly after, according to his epitaph—"Of sorrow at the loss of Sir Thomas Baines" They were both buried in the chapel at Christ's College, Cambridge, where in memory of their friendship Finch founded two fellowships and two scholarships

BENEFACTORS OF THE COLLEGE

Among the great benefactors of this College whose names cannot be passed over in silence are the two Hamey's, father and son Theodore Goulston, founder of the Goulston lectures, Sir Theodore Mayerne, Dr Richard Caldwell, who with John Lord Lumley founded the Lumleian lectureship, Lady Sadlier, founder of the Croonian lectureship in memory of her first husband, Dr William Croone, Dr William Wood Bradshaw, founder of the Bradshaw lecture, Mrs FitzPatrick, who founded the FitzPatrick lecture on the History of Medicine in memory of her husband Dr Thomas FitzPatrick, and *Dr Gavin Milroy*, one of the pioneers in the subject of public health who left £2000 to endow a lectureship on State Medicine and Public Health and Subjects Connected Therewith Further as announced by Sir Thomas Barlow last year, there is the foundation of the Streatfeild Research Fund endowed with £10,000 in 2½ per cent annuities given by Mrs Eliza Streatfeild for the purpose of the endowment of research, the fund being vested in the joint names of the two Royal Colleges, who act as its administrators

On Dec 16th 1916, the College received through our Fellow, Dr Malins, of Birmingham, a gift of £500 from Mr F W Mitchell to be devoted to the object of the research investigation, and treatment of tuberculosis

On Oct 26th 1916 under the will of Mrs Fanny Hertz, of 40, Lansdowne-crescent W , the College became possessed of a fine portrait of the late Dr J E Bridges, which has been hung in the hall

In addition valuable donations of books have been made to the library

A CRITICISM OF HARVEY'S VIEW

An instructive criticism of Harvey's opinions was published two years ago by the late Professor Curtis, of Columbia University[1] In Harvey's life time he was often asked by his opponents to explain the purpose of the circulation, and he was never able to give a satisfactory reply Why should the blood traverse the lungs, return to the heart be distributed to the whole of the body, and then be brought back again to the heart in order to be transmitted again through the lungs? What did the blood gain by its passage through the lungs? Harvey taught that it was ventilated or cooled there, deriving heat from the heart which was the centre of bodily heat We may wonder why Harvey, following Aristotle, should regard air as cooling fire Surely the effect of air on fire must have been known to him, and it certainly seems strange that Aristotle should have said that air keeps fire from consuming the fuel too fast, was he not familiar with a smith's furnace, and with the manufacture of charcoal by limiting the access of air? Harvey knew that air was necessary to a candle and to fire, but did not know why He accepted the doctrine of "spirits," an expression used by Aristotle, Erisistratus, and Galen, as something derived from the air and introduced into the circulation with the blood (Erisistratus) or by itself (Aristotle)

Nearly a hundred years before Harvey's time Realdus Columbus (1559), taught that air was mixed with the blood in the lungs where the transfer took place from the right to the left side of the heart But this great fact that the blood in its passage through the lungs took up air was rejected by Harvey He heads the passage "Spirits not from Air," and he quotes an experiment to show that air does not pass into the blood, as he evidently expected to see the blood frothy if this were so

Harvey maintained these views all his life and never understood the function of respiration, which is not surprising, as he was ignorant of the nature of combustion, of oxidation, of the corpuscular structure of the blood and of the function of hæmoglobin. He was unable to explain the difference in colour of arterial and venous blood, but he sought to minimise the importance of this by pointing out that both when drawn and allowed to stand become nearly the same colour and not of any great difference of either consistency or bulk He knew that during life the arterial blood in the lungs was redder and that the lungs were florid He could never explain why the fœtus could live without air and yet after birth be readily suffocated by air being excluded He always followed Aristotle in the doctrine that the heart was the primordial centre of life, and Curtis thought that Aristotle was familiar with the pulse from observing the incubating egg where the heart makes its appearance early, and to which he consequently attributed all the chief functions of the body, including the affections, feelings, senses, and the like Hence we still speak of the heart as the seat of emotion, of "a change of heart," "Unto Thee all hearts are opened," "Cleanse our hearts," &c It never occurred to Harvey to inquire into the nature of the fumes given off during expiration In Harvey's time the view was generally held that the blood is distributed to the tissues from the liver in spite of the existence of the pulmonary artery and the lungs in life being full of blood, but it is probable that medical men were blinded by the fact that after death the lungs are usually bloodless

Harvey, moreover, was not constant in his allegiance to the heart as the centre and source of the motive power of the circulation, for as early as his lecture notes of 1616 and even in his latest utterances, he regards the blood as endowed with movement, and in his treatise on Generation he asserted the primacy of the blood—"the leaping point"—the pulsating vesicle which he regarded as the first beginnings of the embryo The blood he says, is prior to its receptacle the contained to its container He maintained that the order is first the blood, second the pulsation, and third the vesicle The blood is the "first to live and the last to die" Here as Curtis says Harvey was misled by his confidence in what we call naked eye appearances and his want of better appliances It would have been logical of Harvey had he attributed the pulse and the heart beat to the "leaping blood,' but in his letter to Riolanus he says it was due to the boiling or bubbling of fermentation He thought the swelling of the blood caused by its innate heat stimulated the auricle to contract, and he located this effect just between the openings of the superior and inferior cavæ, where we now place the bundle of His The contraction of the auricles is then the cause of the contraction of the ventricles

Curtis points out the difficulty Harvey was in owing to the backward state of physics He was 14 years younger than Galileo, who was unable to explain the common pump and Harvey's discovery was made public 13 years before Torricelli's momentous work on the movement of liquids. We must therefore recognise that many of the questions which by us are readily answered were in the days of Harvey quite insoluble, but we owe him our gratitude for the enormous advances he made with the means at his disposal.

CAMBRIDGE UNIVERSITY IN THE SIXTEENTH AND SEVENTEENTH CENTURIES

It is of interest to inquire what were the opportunities afforded by Cambridge to the student who desired to study medicine, and how far it was possible for him to set out on the path of such learning as in those days would be regarded as at least preliminary to his studies

The sixteenth century was not favourable to the English Universities They suffered greatly from the religious convulsions of the period Not only were the abolition and disendowment of the religious houses causes of financial embarrassment, but sectarian considerations rather than those of character and learning were paramount in the choice of the heads of houses and professors Religious differences could not but influence the willingness of parents to send their sons to the universities and the resulting decline in numbers with the consequent loss of pupils' fees, impoverished the University exchequer, and such was the lowering of the standard of scholarship that the libraries were spoiled by the selling of so-called "useless" books

The University in the Reign of Edward VI

On the other hand, in the reign of Edward VI (1547-1553) were founded the five Regius professorships in Divinity, Civil Law, Physic, Hebrew, and Greek, each being endowed with a stipend of £40 and so far as it goes we may take the professorship of physic as some evidence that the study of medicine was not altogether ignored The first incumbent of the chair was Dr John Blythe, of King's College, an M D of Ferrara, for at this time and perhaps for a century later Cambridge men had to go abroad for instruction in strictly professional subjects John Caius left Cambridge in 1539 for Padua, where he lectured on Aristotle, in return studying "Medicine and Anatomy," which is some evidence that at Cambridge these subjects were less cultivated than Greek

In the reign of Edward VI the university attracted many students, of whom too many were absorbed in theological controversy (Ascham), moreover it was complained that the majority were mere boys, the sons of wealthy parents, who never became serious students but by their presence interfered with the attendance of a poorer class who would give up their whole time to study The prevailing spirit of the university was indolence In 1558 Caius had spoken of the disappearance of "the poor modest diligent student who rose early, lived on scanty fare and respectfully capped his seniors" Gone, too, were the dignified elders of former times, of sedate countenance and stately mien, punctilious in wearing academic dress and punctual in attendance at the disputations in the schools The undergraduates had discarded long gowns and caps their garments were gaudy, they gambled and drank, and discipline was so much relaxed that those whose misconduct led to their expulsion from one college had no difficulty in obtaining admission to another

The offices of the University became sinecures, for example, there seemed to be no objection to Ascham, the public orator of the University, living abroad while Ridley retained his Mastership of Pembroke when Bishop, at first of Rochester, and afterwards of London The Doctor's degree was taken in scarcely any faculty, and as there were no examinations and disputations had become neglected such as were given could scarcely be regarded as evidence of learning or ability If Cambridge had not sunk as low as certain German universities which Bucer condemns fo giving degrees for money yet there was much indolence among the resident Fellows, who lived like drone bees on the fat of the colleges

---

[1] John G Curtis M.D LL D Harvey's Views on the Use of the Circulation of the Blood New York Columbia University Press 1915

In the new code of Edward VI, introduced in 1549, the text-books of the professor of medicine were to be Hippocrates and Galen

Foundation of Caius College

In the reign of Mary (1553–1558) there was little in the state of the University to give satisfaction to any lover of learning and the only fact which at this time can be regarded as conferring a real and permanent benefit upon the University was the foundation of the College that bears the name of Dr Caius, who was private physician to the Queen was nine times elected President of this College, and bore a professional reputation inferior to none of his contemporaries in this country

Dr Caius was a staunch Catholic, but he had travelled and seen much of men and things so that he possessed an open and tolerant mind. He had studied anatomy under Vesalius at Padua, had visited other Italian universities, and had formed the acquaintance of the chief scholars of France and Germany Being unmarried and wealthy and somewhat of a recluse he retired to Cambridge, where he became a Fellow of Gonville Hall In 1557 he obtained a license from Philip and Mary to refound the College as co-founder with Edmund Gonville and Bishop Bateman, endowing it with the manor of Croxley and Snellshall and several other properties When the College was reconstructed in 1572 it was to consist of a Master 13 Fellows, and 21 scholars, the Master being a Bachelor or Doctor of one of the three faculties

It is noteworthy as bearing upon the question of the state of medical education in Cambridge that the holders of medical Fellowships and *those only* were permitted to repair for the prosecution of their studies to the continent for says the statute Theology and Civil Law may be studied just as well here as there and it is fair to infer that medical science could not These travelling Fellows were required to go to a 'good school, preference being given to "Padua, Bologna, Monte Pulciano and Paris"

Neglect of Learning

On the accession of Elizabeth the fresh instructions to the Commission for the Reorganisation and Reformation of the Universities followed closely those (1549) in the reign of Edward VI. but with the notable omission of the clause for the foundation of a Chair of Medicine and one of Civil Law It is not necessary to recount the troubles and differences which occurred at Caius College owing to the personal unpopularity of Caius who was disliked by the majority of the Fellows and who retaliated by showing his contempt for their indifference to learning and their lax conduct the manners of the students of this period leaving much to be desired

We have seen that a generation before the study of Greek was pursued with much success at Cambridge, but it had become so neglected that eminent scions of the University like Whitgift and Walter Haddon were ignorant of it and Giordano Bruno who visited England and Oxford in 1582 complains that the Oxford undergraduate drank too much beer," while his seniors were 'pedantic and stupid,' but perhaps it is unfair to assume that these faults extended to the sister University Companionable behaviour the capacity to sit long at table after dinner and supper were more helpful to a degree than reputation acquired in the schools or any display of ability there evoked

The attendance upon the lectures of the University professors fell off no doubt in part in consequence of the development of the college system undergraduates preferring to get such instruction as they desired in the class-rooms of their college tutors, but if to the college system may be not unfairly attributed the decay of professorial teaching at Oxford and Cambridge it may on the other hand be credited with having preserved these institutions from such stains on morals and manners as still mar the reputation of the chief German universities

When Caius was in Italy he was a zealous disciple of Giovanni di Monte (1508–1552), who was the first modern to teach medicine at the bedside which he did at the hospital of St Francis Unfortunately Caius did nothing to transplant this method to his native country, and it was at least two centuries before clinical teaching was practised even in a rudimentary fashion in British hospitals

Francis Glisson Regius Professor of Physic at Cambridge

The career of Francis Glisson, a former President of this College, illustrates to some extent the state of medical education at Cambridge where he was Regius professor of physic from 1636 until his death in 1677 He entered Caius College in 1617, graduated B A. in 1621 and M A in 1624 M D in 1634 He lectured at first on normal, morbid, and comparative anatomy, and in 1640 he gave the Goulstonian lectures of this College Up to this date—that is, four years after being appointed Regius professor—he lived in Cambridge but in 1640 he took a house in Colchester, where he 'soon obtained much practice" and where he continued to live until after the siege of that city, when he became much impoverished and moved to London. Here he took a house in New street, in the parish of St Bride's, and resided there up to his death in 1677 He was President of this College in 1667–8–9 In 1675 the University obliged him to appoint Dr Brady as his deputy at Cambridge, but the fact that he was non resident for over 40 years of his incumbency of the professorship may not unfairly be taken to indicate the little interest felt in medical education at Cambridge.

As is well known Glisson was an energetic student of his profession and published many valuable monographs, especially that on Rickets and on the Anatomy of the Liver, by the latter his name has been preserved and is familiar to all medical students from Glisson's capsule" applied to its external fibrous sheath His portrait painted at the age of seventy five is in the possession of this College

WEBSTER'S 'EXAMINATION OF ACADEMIES"

One looks to Webster's book, the "Examination of Academies'[2] for a criticism of the work of the University at or about Harvey's time, but it is disappointing Webster was evidently a fanatical puritan who found fault with the Universities because they professed to train men for the ministry whereby they are said to fill them with vain knowledge He expressed doubt whether the knowledge of Greek and Hebrew could in any way aid the right understanding of the Gospel and thought that only the Spirit of Christ could convey this information. He praised such mystics as Jacob Boehme, he believed in the existence of a Heavenly dialect which was what John heard and God used in speaking to Adam, that animals probably communicated with one another by it

He objected to the Aristotelian philosophy and preferred to it the teaching of the Rosicrucians, and that of our 'learned countryman' Dr Fludde. He condemned the medical profession for adhering to what he calls "ignorant wicked and blind Pagans' for neglecting magic and cabalistic science and that "great book" the 'Macrocosm' of Paracelsus He quoted with approval the saying 'For the Lord hath created the physician not the schools," and he condemned the neglect of that laudable, excellent and profitable science' of physiognomy, the neglect of the science of Celestial signatures, and the study of natural dreams

Coming to more reasonable criticism he found fault with the uniformity of method followed in teaching by the slothful performance of the Acts there being only four in the year to these being conducted in Latin which tended to obscurity and to the neglect of our mother *tongue* He says that the Romans used Latin and prohibited Greek"(!) while the Greeks wrote in their native language. He thinks too much importance is assigned to the opinions of the ancients and that Lord Bacon has indicated a better method than that of the scholastic philosophy, that physics and chemistry should be taught by laboratories as well as libraries

While there is much in this with which a modern would agree the criticism on the whole is peevish and unreasonable and suggests nothing that has any direct bearing upon the improvement of medical education

Webster seems to have had small right to pose as the critic of the Universities for it is at least doubtful whether he was at any time a member of either of them. He speaks of himself as educated at Cambridge but no trace of him can be found in the University registers according to the Dictionary of National Biography He was ordained in 1632 curate of Kildwick in Craven in 1634 and Master of the Grammar School at Clitheroe in 1643. In the Civil War he seems to have taken the Parliamentary side and was surgeon and chaplain to a regiment in the Parliamentary army, becoming a Nonconformist and being intruded as vicar of Mitton in Yorkshire and also at *All Hallows in Lombard-street* He acquired some fame as a preacher but later on he fell into discredit, for his books were seized in 1657 and he gave up the ministry Later in life he studied metallurgy and practised medicine He died at Clitheroe in 1682

---

[2] Academiarum Examen, London, 156

"THE VINDICATION OF ACADEMIES"

Webster's book was answered by John Wilkins and Seth Ward in the "Vindication of Academies"[3] In this defence of the Universities the authors complained that Webster, and even Hobbes, were ignorant of the present state of the Universities and of the grounds of those arts and sciences which they pretended to improve Surprise is expressed that the Universities should be condemned as rigidly bound to Aristotle and accused of ignoring the modern advances in knowledge which have modified his teaching On the contrary, all modern ideas were freely discussed—the anatomical and magnetical philosophy and the Copernican astronomy That both in the public lectures and private classes of the Universities those things which they are accused of neglecting are taught and are well learnt Particular exception was taken to the criticism which maintained that University teaching is not only useless but harmful to candidates for the ministry, for such academic knowledge "*added to the gifts of grace must be only helpful* and not injurious"

On the other hand, Webster's praise of the Rosicrucians, of Jacob Boehme and of judicial astrology show him to be a credulous fanatic Further, Webster is accused of plagiarism, of stealing whole sheets of Gassendi's book, and of being wholly dependent upon those translations to which he had access for his knowledge of foreign writers The accusation that the study of chemistry was neglected was denied and with some reason it was pointed out that, the practice of medicine being an art which is based on observation and experience, new discoveries in anatomy do not always involve alterations in practice equal to that in theory, but have often confirmed and established practical rules

Webster's objection to the use of the term "divines" as blasphemous is treated as ridiculous, but it is conceded that "theologian" is better, and the complaint of the use of the Scriptures in scholastic exercises is inconsistent with the desire expressed that Christian principles should be introduced into the schools of physical learning Moderns may agree with the contention that students should be taught to use their hands in laboratory work, but there is force in the objection that the wishes of parents must be respected, and that in the sixteenth and seventeenth centuries it was not thought desirable to teach young gentlemen natural philosophy, chemistry agriculture, or mechanics but they should be trained to be rational and graceful speakers and fitted to move in polite society

Webster's critic John Wilkins, the Bishop of Chester, was one of the most learned and estimable men of that age He adhered to the Parliamentary side in the Civil War, and was Warden of Wadham College in 1648 He had the reputation of being a wise, beneficent, and tolerant Head of the College, and he may be justly called the founder of the Royal Society The weekly meetings of the London philosophers when held in Oxford took place in the Warden's lodgings Although siding with the Commonwealth he preserved the University from the ignorant commanders and soldiers who, unrestrained, would have demolished all places and persons that pretended to learning He was afterwards appointed Master of Trinity College, Cambridge where he was greatly honoured and loved but at the Restoration he was deprived of this post, as it had been long promised to Henry Ferne He was made Prebend of York and Dean of Ripon He procured the incorporation of the Royal Society in 1662 becoming its first secretary He lost his library and valuable MSS in the great Fire of London He was made Bishop of Chester in 1668 and died in 1672 He is generally supposed to have written the preface to Seth Ward's "Vindiciae Academiarum"

'AN ARK FOR SUBMARINE NAVIGATION'

Bishop Wilkins was interested in many things, and Professor Joly of Trinity College Dublin has recently drawn attention[4] to his little volume entitled 'Mathematical Magic," in which one chapter is headed "Concerning the Possibility of Framing an Ark for Submarine Navigation, the Difficulties and Conveniences of such a Contrivance"

This invention seems to have been produced by a Dutchman named Cornelius Drebbel, who was born in Alkmaar in Holland in 1572, and came to England in 1604, where he secured the favour of James I, and was given lodgings in Eltham Palace He left England at the invitation of the Emperor of Germany, but was involved in the misfortunes of the Thirty Years War, when he was thrown into prison Through the intermediation of James I his release was procured, and he returned to England, where he remained until his death in 1634 He appears to have enjoyed the esteem of his contemporaries, especially of the Hon. Robert Boyle, who refers to him as a "deservedly famous mechanician and chymist"

The great interest to us of Drebbel's work is that he appears to have been much ahead of his contemporaries in appreciating the function of respiration It is said that he built a ship in which a man could navigate under water from Westminster to Greenwich In the boat "a person could see under the surface of the water and without candlelight as much as he needed to read in the Bible or any other book" This remarkable ship was in 1645 yet to be seen lying in the Thames or London river (C van der Oonde). Boyle accepted the testimony of what he called "a few credible persons" that Drebbel could enable men to continue under water without suffocation or even inconvenience for as he says, it is "not the whole body of the air but a certain quintessence or spirituous part of it that makes it fit for respiration which being spent the remaining grosser body of the air is unable to cherish the vital frame" So that besides *the mechanical contrivance of his vessel he had*—

> "a chemical liquor which he accounted the chief secret of his submarine invention, for when from time to time he perceived that the finer and purer part of the air was consumed or overclogged by the respirations and steams of those who went in his ship he would, by unstopping the vessel full of his liquor, speedily restore to the troubled air such a proportion of vital parts as would make it again for a good while fit for respiration, whether by dissipating or precipitating the grosser exhalations or by some other intelligible way"

According to Boyle, Drebbel kept the nature of the liquor a close secret and justified his own inquiry because the man and his invention were so extraordinary, all the more so as it was 150 years before the discovery of oxygen by Priestley and Lavoisier and of the part played by it in respiration It was not until 1681 that John Mayow published his conclusion that respiration and combustion are analogous phenomena Drebbel must have discovered some means for removing from respired air its poisonous properties as by drawing it through lime water to absorb the carbon dioxide, by which it would be possible to prolong the voyage, and the ventilation of the boat may have been assisted by pipes going to the surface the air being drawn in by fans or pumps It is certain that the bishop realised the difficulty presented by respiration in the problem of submarine navigation and that he fully appreciated the work of Drebbel in overcoming this part of the problem

While Harvey failed to grasp the function of respiration and set aside the suggestions that had been made by others under the crude form of the action of "spirits" on the blood it is quite plain that these contemporaries of Harvey allowed their minds to run farther than his on the chemical side of these questions and were closer than he to understand the nature of the physiological questions involved His failure in this respect was probably due to his ignorance of chemistry, which Aubrey says he was wont to undervalue and speak against those who practised its doctrines

BISHOP WARD —OTHER CRITICISMS OF THE UNIVERSITIES

Seth Ward successively Bishop of Exeter and Salisbury was a distinguished mathematician, mathematical lecturer at the University of Oxford and afterwards Savilian professor of astronomy in 1649 He entered as a Fellow Commoner at Wadham when John Wilkins was warden and when the fame of the college attracted many men of eminence These gatherings probably constituted the nucleus of the Royal Society After the Restoration he was made successively Prebend Dean and Bishop of Exeter He was subsequently translated to Salisbury and became Chancellor of the Order of the Garter His controversies with Hobbes and Webste caused him some trouble He is the reputed author of the "Vindiciæ Academiarum," in which he replied to the criticisms of the Universities which Webster and Hobbes had published in the ' Examen Academiarum "

---

[3] Vindiciae Academiarum, Oxford 1654

[4] The Origin of the Submarine Blackwood's Magazine July 1917

Hobbes the author of "The Leviathan" (1588–1679), was a somewhat bitter critic of the Universities in his day, particularly on the ground of their adherence to the Aristotelian philosophy and physics He says, "The philosophy schools through all the universities of Christendom grounded upon certain texts of Aristotle," and these institutions were merely useful as a handmaid to the Roman religion , they rendered no knowledge of the subordinate and secondary causes of natural events or "physiques," but merely empty words Thus they said that bodies sank because they are heavy or because they desire to be at rest He also criticised their teaching of the civil law, but although there was doubtless much with which to find fault, he says nothing about the art of medicine or the way in which it was taught

Dr C A. Mercier[5] is of opinion that Paracelsus and van Helmont had much to do with preparing the ground for the reception of Harvey's new doctrine He thinks that by their bold challenge to the Aristotelian doctrines they rendered it possible for Harvey to state his novel opinions without being regarded as uttering blasphemy, but he is almost as severe a critic of Oxford and Cambridge as was Hobbes 200 years earlier He quotes a statement of Averroes that Aristotle is "the perfection of truth, that his understanding attained the utmost limit of human ability," and that ' it may truly be said of him that he was created and given to the world by Divine Providence, in order that we might see in him how much it is possible for a man to know " This tribute may seem exaggerated to the non academic mind but "it would not be considered at all exaggerated in the University of Oxford even to day " He gives no facts whatever in support of this charge However there may be something in what he says, for had not Paracelsus and van Helmont shown that Aristotle could be contradicted without calling down fire from heaven, Vesalius might not have had the courage to publish his discovery of the non porosity of the cardiac septum

Teaching of Medicine at Cambridge in Harvey s Time

It is not easy to trace any evidence of the teaching of medicine at Cambridge in the time of Harvey In Vol III of Venn s ' Biographical History of Gonville and Caius College ' (p 253) we find the following —

"It will be observed that no reference has been made in the above sketch to any such officer as a medical lecturer The fact is that though the College had for centuries enjoyed a medical reputation, no trace of any systematic instruction in the subject can be discovered until very recent times Indeed, the earliest lecturer recorded by tradition is the late Sir George Paget, who is known to have held the office from about 1848 until he ceased to be a Fellow in 1852. Since that date such lecturers have been regularly appointed The increased scope of the work, owing to the great addition to the number of students, was recognised in 1881, when the title was changed from Medical Lecturer to Lecturer in Natural Sciences and Director of Medical Studies That some instruction, however, in the shape of what we should now call anatomical demonstration was occasionally given in the College can be proved by one or two interesting facts In the first place, in the register of the parish of St Michael—the College lies in the parish—there is an entry of burial under the date April 6th, 1601, of ' Mr Hutton, the anatomyr of Kev's College ' "

Venn took it for granted at first that this gentleman s connexion with anatomy was of the active kind, and that we had here evidence of a very early demonstrator in the College But it now seems certain that he played the part of the subject, for it is recorded that Dr Grimston, "one of our Fellows " made a dissection in the College just four days before That similar instruction was carried on 25 years later seems plain from the statement of Dr Joseph Mede, that he attended anatomy lectures in "our College " In the register of Great St. Mary's the parish in which the schools, now absorbed into the public library were situated, several such entries are found The earliest of these is in 1566 when it is recorded that "John Figgen mad anotomy at the scholes and buried here, the 12th March ' This was during the residence of Dr Caius, seven years before his death

Professor A Macalister informed Dr Venn that this is the earliest contemporary record known to him of the actual performance of human anatomy in England Again in 1628 there is an entry that "John Smith, a prisoner at the castle that was anatomised, was buried " In a note, Dr Venn says that it perhaps accounts for the prefix "Mr " to Hutton s name, a title at that time confined by University usage to Masters of Arts and Fellow Commoners, in the direction of Dr Caius that the burial of such anatomised bodies should be ' orderly and reverential "

In the same volume (p 47) we find the following "On the same day (Patent Roll, August 1st, 1564) is added the Royal License for the purchase of the houses from Trinity A new and very important concession was included in this license It was a formal grant from the Queen (Elizabeth) of bodies for dissection to the effect that they and their successors shall have for ever, at their free discretion and will, without the contradiction of anyone, two human bodies for anatomy, condemned by law for theft or homicide and dying in the town castle or county of Cambridge And that they may freely dissect them at their will, with the reverence due to the human body, for the increase of medical knowledge, and this without any payment ' Dr Caius gave careful directions in his statutes concerning these dissections, desiring that 'every year during the winter there shall be spent by the students of our College, on anatomy and on the worthy burial of the dissected bodies at S Michael's 26/8 The president and everyone residing in College to attend the burial of the remains with as much respect and ceremony as if it were the body of some more dignified person , and this on account of the advantage they have thus received And the Master shall see that the students of medicine do not treat the body with any lack of respect or humanity ' It is to be feared that very inadequate use was made of this privilege "

In his "Advancement of Learning" Bacon mentions that the study of medicine was based upon the use of dead bodies for dissection

It is further evidence that dissection was practised in Cambridge in the seventeenth century that Sir Charles Scarburgh (1616–1694), who was a Fellow of Caius College, published a manual on dissection (' Syllabus Musculorum "), but there appears to have been no dissecting room, public or private until after the passing of the Anatomy Act, 1832 Science and its votaries, indeed found no permanent home at Cambridge in the time of Harvey Gilbert of Colchester, who as Bacon says had made a philosophy out of a load stone, had been long removed to London, where as Royal physician he enjoyed favour and good fame, and died in 1603 Physiology as a subject did not exist, and the knowledge of the functions of the organs apart from their structure, was elementary and very often fundamentally erroneous In spite of Bacon s commendation, morbid anatomy was entirely neglected perhaps because, as he pointed out, how much more difficult was this study than that of normal anatomy, the latter being presumably uniform in all healthy subjects, while the former presented endless variety Its difficulty undoubtedly hindered any advancement, for it is not until the second half of the nineteenth century when fairly complete post-mortem examinations were made on the bodies of all persons dying in hospitals, that the subject became familiar, and morbid appearances grew to be generally known to hospital physicians and were appreciated to a less extent from students

Impulse given by Harvey to British Physiology

There can be no doubt that in the *sixteenth and* seventeenth centuries those Cambridge men who desired to study scientific medicine could not do so at home, and resorted to the Italian universities to study under such great masters as Vesalius Fallopius, and Eustachius, whose success was rather in descriptive anatomy than in physiology Harvey s work was of great importance because although he added no new facts, he placed a new interpretation on what had been more or less common knowledge for 2000 years and stimulated an advance in medicine which has continued up to the present time. This advance was mainly due to his employment of vivisection, by which method he laid the foundations of physiology and thereby of the progress of medicine Physiology has been rightly called the Institutes of Medicine which must march hand in hand with pathology and be its guide Its progress depends upon the advance of many sciences especially of chemistry in that department which we call organic or physiological This was a new science 40 years ago and has been built up within the lives of many of us It has opened out a wide prospect and gives promise of revolutionising medical study

---

[5] Paracelsus and van Helmont: Proc of Royal Soc. of Med 1915 vol ix Section of History of Medicine.

The impulse that the work of Harvey gave to British physiology is shown by naming those who followed him in the next 100 years

Thomas Wharton (1614–73), physician to St Thomas's Hospital studied at Cambridge and Oxford, discoverer of the submaxillary gland and author of Adenographia (1656)

George Joyliffe (1627–58), M D Cantab , F R C P , discoverer of the lymph ducts

Francis Glisson (1597–1677), M D Cantab , Fellow and President of this College author of famous monographs on Rickets and the *Anatomy of the Liver*

Thomas Willis (1621–95), M D Oxon , F R S , F R C P , recognised saccharine diabetes and described the Anatomy of the Brain (the circle of Willis)

Richard Lower (1631–91), M D Oxon , F R S , F R C P , performed transfusion

Edward Tyson (1650–1708) and Samuel Collins (1618–1710) were *comparative anatomists*

Clopton Havers described the Haversian canals

William Cowper or Cooper (1666–1759) described "Cowper's" glands

ADVANCE OF MEDICINE IN SECOND HALF OF NINETEENTH CENTURY

But it cannot be claimed that at Cambridge or elsewhere there was any real progress in medical education Here and there men of genius made discoveries, but they were not aided by any organisation, either inside or outside the university or medical school Men like the Hunters did their work at their own expense, and for many years to come even the teaching of anatomy owed most to what was done in private schools

The best that can be said for British medical education is that it was based upon some genuine knowledge of practical anatomy and bedside acquaintance with diseases But it was not until the second half of the nineteenth century that a true spirit of reform entered into the schools In no place was this more manifest than at Cambridge Although it is still necessary, and probably always will be, for the Cambridge student to seek clinical experience elsewhere, he may find at Cambridge all that he desires in laboratory opportunities and, under due limitations, for clinical research

If Cambridge has proved itself worthy of its association with the illustrious Harvey this is equally true of the great hospital of St Bartholomew's, with which perhaps his professional connexion is more generally recognised Harvey left Cambridge apparently as soon as he had completed his arts curriculum, taking no part of his medical education there, and although he returned there for his degree, he owes to Italy the instruction that opened the way for his great discoveries

HARVEY AS PHYSICIAN TO ST BARTHOLOMEW'S HOSPITAL

Of his labours as a physician at St Bartholomew's we know little, and what records remain do not impress us very favourably with the work done in those days by those who held such appointments as that of Harvey When he was originally appointed he was only obliged to attend once a week, and he was never formally required to visit the wards The number of patients seen in the hospital must have been very small, for as late as 1749 the numbers are given as—in patients, male 16, female 15, out-patients male 50 female 50, each week , and there is no reason to believe that a hundred years earlier they were more numerous

Apparently the patients were obliged to come to the doctor and not the doctor to the patients as one of the rules says —

"It is the duty of the matron and sisters to complain to the doctor if any poor lurk in the house and do not come to him at his sittings or take the medicine he prescribes, but cast it away and abuse it

It is difficult for us to understand the position of such a man as Harvey holding a post which, to us seems scarcely likely to afford him any return in the way of useful experience The salary was inconsiderable some £20 a year with an allowance for fuel and "livery," but it is possible that the appointment indirectly led to a certain amount of practice for undoubtedly he made money by his profession, although Willis suggests that his brother Eliab employed the ' small capital" accumulated by him during his active years of practice and before the breaking out of the Civil War to such good account that he actually died a rich man

The period during which he may have earned a considerable professional income must have been from about 1607 to 1630

HARVEY'S LATER YEARS HIS GIFT TO THE COLLEGE.

After the latter date, when he went abroad with the Duke of Lenox it is doubtful whether he ever had much opportunity for practice In 1633 he went with Charles to Scotland, whence he followed him to Oxford (1642) and in 1646, on returning to London, he resigned all his appointments, and as his wife was dead he took up his residence with his brothers Eliab and Daniel It was then that Harvey felt himself fully justified in making over his paternal estate, then worth £56 per annum, to this College as a free gift during his life and as a provision for the objects of which this annual oration forms part

He died at the advanced age of 80 on June 3rd, 1657, and I cannot do better than repeat the words of Willis —

"So lived, so died one of the great men whom God in virtue of his eternal laws bids to appear on earth from time to time, to enlighten and to ennoble mankind "

THE TREATMENT OF

TRENCH FEET AND ALLIED CONDITIONS BY BIER'S METHOD OF PASSIVE HYPERÆMIA

BY PHILIP TURNER M S LOND , F R C S ENG ,
MAJOR, R.A.M C

(A Paper read before a Medico Chirurgical Society March, 1917)

DURING and after a spell of severe weather we have had large numbers of cases, as doubtless all hospitals have had diagnosed as "trench feet," "frost-bite of feet," and, of course, "I C T ' feet This has given me the opportunity of trying Bier's method of treatment by passive congestion in a considerable series of cases, the results of which I propose to bring before this meeting Though I have had no access to statistics I feel sure that the relative number of these cases is less than it was either in the winter of 1915–16 or 1914–15 This is doubtless due to the improved prophylactic measures taken, and it is rather suggestive that large numbers of cases come from certain units, while others appear to be almost free Though prophylactic measures have been attended with so much success, there is, so far as I know, no very satisfactory method of treating cases which have once developed, and I hope that the results obtained by the method of passive congestion will lead to this method being given a more prolonged and thorough trial

A memorandum on the "Etiology, Prophylaxis, and Treatment of Trench Foot," by Médecin Majors Raymond and Parisot, was circulated to the various hospitals, and a good many of the members of this society will doubtless have read it This memorandum is of great interest and I shall refer to it on several occasions The actual treatment recommended here consists in the application of compresses of sterile gauze soaked in a solution of powdered camphor and sodium borate in boiled water This is covered with cotton wool and impermeable tissue We have had no cases here in which this treatment has been started before arrival, and we have had no opportunity of starting it here so I have no practical experience of it , but I must say that I should have expected these cases to do better with a method in which the feet were kept dry rather than with one in which wet compresses were employed

Causation

Before speaking about the treatment of trench foot it will be necessary to say something about the causation of this condition and to consider the pathological changes which actually occur This subject was investigated by Professor Lorrain Smith, Professor James Ritchie, and Dr James Dawson[1] who succeeded, by submitting them to cold, wet, and constriction of the limbs, in producing a similar condition in rabbits Their conclusions may be summed up by saying that they consider the condition to be essentially one of inflammation brought about by direct action of cold on the tissues, and that histological examination of the affected parts showed that the chief changes took place in the blood-vessels They regard the influence of infecting micro-organisms as *unimportant*, and found that when these were present they did not seem to be the cause of the inflammatory process They also point out that the essential difference between trench foot and true frost-bite is that in the latter the direct action of severe cold leads to the complete destruction of the vitality of more or less extensive masses of tissue, while in the former the effect of cold and wet, combined with certain factors which impede the circulation in the extremities, is to produce this inflammatory reaction

---

[1] THE LANCET 1915 ii 595.

The view of the pathology taken by Médecin Majors Raymond and Parisot in the memorandum already mentioned is very different They regard trench foot as caused by a special infection of the foot and claim to have isolated the infecting agent, a mould, *Scopulariopsis koningii*, which is found in the mud of the trenches, and which penetrates the feet at the site of the grooves at the side of the nails or through excoriations of the skin They compare trench foot with Madura foot and regard cold as only of secondary importance in its causation. The suggestion that trench foot is due to a specific infection is I believe, quite new, and so far we have had no opportunity of searching for the presence of this mould. Captain G Richardson, R.A.M.C, has, however in a number of cases of trench foot in which there were sloughs, blisters or gangrenous areas, examined the discharge bacteriologically, and in all cases found only the usual organisms one would expect to find in such lesions with ulceration of the skin. I do not think that many will agree with Majors Parisot and Raymond that cold and wet are of only minor importance Indeed, one may go so far as to say that the great majority of medical men who have had charge of these cases, while admitting the importance of other factors, would regard prolonged exposure to cold and wet as the most essential cause of trench foot As regards there being a special infection by a mould, one can express no definite opinion at present but must wait further experiments and researches which will doubtless be made to test the correctness of this theory

At present, then we may accept the account of the pathology by Professor Lorrain Smith, Professor Ritchie, and Dr Dawson but in one respect I am not quite in agreement with their explanation—viz., as to the importance of the part taken by micro-organisms, especially in the more severe cases In the milder cases where the symptoms are limited to swelling congestion and alterations in sensation, the changes produced by micro-organisms are doubtless unimportant but in the more severe cases in which one finds septic blisters sloughs, and ulcers often surrounded by inflamed areas or actual cellulitis and sometimes gangrenous areas of considerable extent and some depth, the part taken by micro-organisms in their production must surely be of the greatest importance The discharge from such cases has often a distinctly foul odour, and it was in the discharge from such cases that Captain Richardson found organisms present such as are usually present in or on the skin. Another point as showing the importance of organisms in these cases is that tetanus has occurred with sufficient frequency in cases of trench feet as to render it desirable that the usual prophylactic dose of serum should be injected in all cases whether the skin is broken or not.

My view of the pathology of trench foot may be summed up as follows The condition is primarily caused by prolonged exposure to wet and cold, combined with other factors which impede the circulation These set up the inflammatory changes described by Professor Lorrain Smith. The vitality of the tissues is lowered to such an extent by this that septic organisms already present in or on the skin possibly in fissures or excoriations are enabled to set up more or less severe septic inflammatory processes resulting in the development of blisters sloughs, and gangrenous areas Needless to say this view as to the part played by micro-organisms is derived entirely from clinical observations but some such explanation appears to be necessary to explain the more severe cases This is a point of considerable importance, for if it is granted that septic organisms play an important part in the process even though that part is secondary and indirect their intervention must be taken into account in whatever line of treatment is adopted

Classification

It will be convenient here to facilitate further reference, to arbitrarily divide cases of trench feet into three groups (*a*) Mild, where the skin is unbroken and the symptoms are swelling and "congestion" (really a bluish discoloration due to hæmorrhagic infiltration of the superficial tissues) combined with sensory disturbances (*b*) Moderate, where blisters, or small sloughs, or black and apparently gangrenous areas are present, and the sensory disturbances are more marked (*c*) Severe, where there are extensive sloughs ulcers, or gangrenous areas of considerable extent involving, perhaps, several toes

With regard to this grouping of cases it may be pointed out that the changes in trench foot are usually superficial, and that appearances are often very deceptive It is no uncommon thing to see a patient who appears to have one or more toes completely gangrenous, or to have large patches of apparently deep and spreading gangrene on the dorsum or side of the foot, and yet on treatment such areas shrivel up and separate leaving scarcely a scar underneath Improvement sometimes takes place very quickly, and in some of these apparently severe cases the freedom from scarring on recovery shows that the deeper layers of the epidermis cannot have been damaged beyond recovery, even though when first seen the condition may have looked so serious as to suggest that amputation of one or more toes would be necessary I do not of course mean to say that gangrene of the toes and massive gangrene of the tissues of the foot never occur or that amputation is never called for, but I am sure that this is quite rare When extensive sloughing and gangrene are present I believe that this is largely due to a virulent secondary infection and that early treatment has been impossible

Method of Treatment

The question of prophylaxis is of the very greatest importance, but we are now concerned only with the treatment and not the prevention of trench foot. A consideration of the above points will show that treatment should be directed to (*a*) cleansing of the foot and the prevention of secondary infections and (*b*) the treatment of the original inflammatory changes and also of any secondary infection which may have developed.

(*a*) *Cleansing of the foot* —The importance of this is very rightly insisted upon by Major Parisot and Major Raymond, who recommend "a careful cleansing, almost a surgical cleansing" with special soft soap containing camphor and sodium borate The method I have adopted has been as follows. The feet are cleaned with ordinary soap and water and the nails are also cut and cleaned. The feet are then painted over with a solution of 1 per cent picric acid in methylated spirit, and this application is repeated at first daily and later on alternate days This solution which I have used and recommended from the early days of the war for the purpose of sterilising the skin in military surgery is most efficient. It penetrates to the deeper layers of the epidermis and never causes dermatitis or irritation of the skin. Having been treated in this way the feet are wrapped in sterile gauze and left exposed to the air until the patient finds that they are more comfortable when covered by the bed clothes

(*b*) *Treatment of the inflammatory processes* —Bier's treatment by passive hyperæmia is recognised as a satisfactory method of treating many conditions where there is a subacute or chronic inflammation It is also very often successful in the treatment of chilblains. These considerations led me to try Bier's treatment for trench feet. It is applied as follows —

As soon as the cleansing process has been carried out a constricting bandage is applied just above the knee A Martin's elastic bandage cut in half provides a bandage of about the right length and strength If this is not available, an elastic crepe bandage may be used, but these are not so satisfactory as they stretch, and the pressure exerted may diminish or even disappear after a few hours For the first day the bandage is kept on for 18 hours. It is then removed and reapplied after an interval of six hours It is then again applied and on the second and succeeding days is left on for 22 hours in every 24 The bandage should in all cases be applied just tightly enough to impede the venous return, but on no account must it obstruct the arterial supply In many cases there will be no alteration in the appearance of the limb but in some there will be noticed a slight increase in the swelling or the leg below the bandage may feel slightly warmer as the result of the congestion The treatment should be painless and any complaint of pain—not slight discomfort—is an indication for the removal of the bandage I have only had one case in which this was necessary, and even here the bandage was subsequently reapplied without any further complaint of pain

Results

It will now be as well to describe the effect of the treatment It has been pointed out that sometimes there is a temporary slight swelling of the leg below the bandage This soon disappears, and in slight and moderate cases the swelling of the foot has usually quite disappeared in 24 or 48 hours In severe cases it may persist for longer Pain improves rapidly, and in 24 hours has either disappeared or has markedly diminished Anæsthesia improves steadily, but not so rapidly In a moderate case with anæsthesia of all the toes and of the greater part of the dorsum of the foot the sensation will probably be normal in four days, with the exception of blisters and gangrenous spots where the sensation is naturally still deficient In cases of moderate severity blisters and the gangrenous areas shrivel, dry up, and eventually separate, leaving an unbroken delicate pink skin underneath This process is very interesting, and not infrequently there is an extensive desquamation of the skin of the affected part, sometimes of practically the whole foot In extensive cases, after the separation of dried blisters, gangrenous spots, and epithelial scales, there is left a surface of thin pink, soft skin resembling a baby's foot This is naturally very tender, and though the patient can walk in soft shoes, boots cannot be worn until the thin skin has become hardened and accustomed to pressure I cannot help regarding this desquamation and separation of dried gangrenous areas as part of the natural process of cure in these cases of moderate severity, and I think that the treatment by passive hyperæmia considerably accelerates the process The following is an example of a case in which this occurred

Rifleman W F C Admitted Jan 27th, 1917, discharged March 10th, 1917 On admission both feet were affected about equally There was severe *burning pain, especially at night*, and anæsthesia of all toes and about half of the dorsum and sole of both feet. The third and fourth toes of the right foot were very discoloured and appeared gangrenous, as was also the little toe of the left foot There were several other small black spots *There was slight œdema* and also congestion of both feet The patient was unable to walk Bier's treatment commenced on Jan 27th Pain disappeared in 24 hours, also the swelling of the right foot, but the œdema of the left foot persisted for four or five days By Feb 4th both feet were practically normal, and *dried up* sloughs were beginning to separate from the toes The bandages were omitted and the patient got up There was no swelling, but some pain on walking On Feb 5th he was kept in bed, and the bandages were reapplied with immediate relief, and as he had a cold with pyrexia he was kept in bed till the 10th He then got up again and walked well without pain The gangrenous spots separated on Feb 12th, leaving unbroken skin beneath From that date the patient did very well There was extensive desquamation of the congested parts of both feet, so that on the anterior half of the dorsum, including all the toes, the skin, though unbroken, was thin, pink, and very tender He could walk quite well in soft shoes, but was unable to wear boots As it would be a long time before the skin would be sufficiently hardened to enable him to wear boots, and as his age was only 16, he was evacuated to England Owing, however, to another attack of pyrexia he was not evacuated until March 10th

In slight cases, as soon as pain, swelling, and anæsthesia have disappeared, usually after four or five days, the patient is allowed to walk in soft shoes Then after two days boots are worn at first for half an hour daily This period is gradually increased until the boots can be worn for two hours without discomfort when the man is discharged to the convalescent depôt. In "moderate" cases the procedure is the same The patient is allowed to walk as soon as possible in shoes, and is then gradually accustomed to boots A longer period is, however, required before walking is possible and before boots can be worn A large proportion of these cases (I should estimate about 50 per cent) have improved sufficiently to be discharged to the convalescent depôt but in many of the men, especially where there has been extensive blistering or many gangrenous spots with much desquamation, the feet are so tender that several weeks must elapse before they return to even light duty, rendering evacuation necessary When the patients are sufficiently convalescent to get up the Bier's treatment is still continued, the bandage being removed when they get up and replaced when they go to bed, so that the bandage is applied for about 18 hours out of the 24 "Severe" cases always require evacuation to England, for, even under the most favourable circumstances, it must be many weeks before these men are fit to return to even light duty These cases have also been treated in the same way, but owing to pressure on the hospital accommodation it has not been possible to keep any under observation for more than two weeks Even in this time, however, there has been rapid improvement Swelling, pain, and anæsthesia diminish, sloughs and gangrenous areas rapidly dry up, lines of demarcation form, granulating surfaces assume a more healthy appearance, and surrounding areas of inflammation subside Thus even in these severe cases the symptoms rapidly diminish and the natural process of cure is hastened

It may be asked whether the *improvement in cases treated* by Bier's method is really due to the Bier's treatment and not to the rest, general treatment, and picric acid application That it is due to the former is proved by the results in some cases where one foot has been severely, the other only slightly, affected The bandage has only in these cases been tried for the severely affected foot, while the other treatment has been applied equally to both In such cases one nearly always finds that the foot treated by Bier's method is in a couple of days better than the other more *slightly affected* foot, which has not been so treated In conclusion, I would point out that the treatment is simple and painless and requires no special apparatus beyond the bandage

ON THE
TREATMENT OF A SERIES OF RECENTLY INFLICTED WAR WOUNDS WITH FLAVINE

(A REPORT TO THE MEDICAL RESEARCH COMMITTEE)

By HAMILTON DRUMMOND, F R C S EDIN
AND
J W McNEE, M D GLASG ,
CAPTAINS ROYAL ARMY MEDICAL CORPS
With an Introduction by
Surgeon General Sir ANTHONY BOWLBY

INTRODUCTION

THE report by Captain Drummond and Captain McNee is the result of a very careful study of the effect of flavine in recent wounds It is evident that the number *of cases dealt* with is not sufficient to enable final conclusions to be drawn, but some of the observations are sufficiently definite for the formation of very definite opinions, and I am in complete accord with those expressed by the authors

In the first place, it appears evident that flavine does not sterilise recent wounds, and that various bacteria *grow freely* in wounds treated with it

Secondly, it appears to cause a very superficial necrosis, of the formation of a fibrinous membrane *if applied* in the strength of 1 in 1000

Thirdly, in spite of the presence of bacteria there is a notable absence of inflammation and of *septic* infections, and in the *cases observed* there were no bad examples of gas gangrene, although anaerobic organisms were present in many wounds in large numbers

Fourthly, healing by granulation is very slow, and the growth of granulations is evidently checked by the presence of flavine

As far as the present *series* of operations goes it is clear that it does not bear out some of the claims made for flavine as a bactericidal agent or as *to* its *harmlessness* to the tissue cells But it appears to be a useful application in the form of gauze soaked in the solution when used as a first dressing to large open wounds, and it *seems to* limit the power for harm of the pathogenic bacteria and to prevent the inflammation of the tissues which is usually caused by bacterial invasion Further observation of many *more* cases is required to establish its value in the treatment of recent wounds

(Signed) ANTHONY BOWLBY
Surgeon General

G H Q July 25th 1917

REPORT

Towards the end of April a sample of flavine was placed at our disposal by Surgeon General Sir Anthony Bowlby, to be tested in the treatment of recently inflicted wounds at the Front. The test has been carried out partly in a casualty clearing station and partly in an 'advanced surgical centre,' situated about four miles behind the lines Almost all the cases were operated upon and the treatment with flavine commenced within twelve hours after the injury, in many instances indeed, only four or five hours had elapsed before the wounds were dealt with All the wounds were therefore in the pre-suppurative stage, in contrast with other tests reported from home It has been possible, through the courtesy of Lieutenant-Colonel Frankau commanding officer of the clearing station, to keep a number of the cases under observation for several weeks thus greatly aiding the observation on the process of healing in the wounds and the investigation from the bacteriological side

Strength of solution employed—The flavine was at first employed in a strength of 1 in 1000, the dilution being made in normal saline solution in which the powder is readily soluble. This strength was used both for the primary stages and for the subsequent treatment by irrigation or otherwise. This routine was soon given up however, as it was found that equally good results ensued if the use of 1 in 1000 solution for the first dressing was followed by the employment of a solution of 1 in 5000 for all subsequent applications. In some cases, also, where the Carrel method of irrigation was being used the strength of the solution was further reduced to 1 in 10 000

Number of cases and number of wounds treated with flavine—In this test a series of 70 cases have been under treatment but as many of the men had multiple injuries, the series comprises over 120 wounds In some cases as many as six serious wounds were present in the same patient The vast majority of the wounds were caused by the fragments of shells or bombs only about eight injuries from rifle or machine-gun bullets being encountered while the test was in progress

Classification of the wounds—The wounds may be divided into three classes both for easy reference, and because the method of treatment differed in each class (1) Flesh wounds including all injuries to soft parts without damage to bone, (2) compound fractures, (3) miscellaneous wounds of special parts—abdomen chest head, and joints

Surgical methods adopted—These naturally depended on the type of injury met with Long incisions, with free excision of damaged muscle and fascia, must be regarded as a cardinal part of all operative treatment in recent wounds no matter what subsequent methods are employed. After this preliminary surgical treatment the wounds treated with flavine were dealt with in the following ways —

1 Primary suture —This method was employed in 30 cases, all being wounds of the soft parts alone In the majority of these the damaged muscle removed at operation was examined bacteriologically and shown to be infected Fragments of cloth, and dirt were also commonly removed from the track of the wound

2. Drainage by tube or gauze strip followed by secondary suture —This was carried out in 10 cases

3. The Carrel method of intermittent irrigation —The perforated tubes were irrigated with the flavine solution every four or six hours This method was chiefly employed for compound fractures and deep or extensive muscle injuries.

4 Gauze packing in open wounds.—This was found very useful in the treatment of many extensive wounds where the Carrel method was not readily applicable for instance in certain types of compound fracture and in amputation stumps where complete closure was impossible.

The gauze packing soaked in flavine could be left *in situ* for several days without changing the dressing

Results of Treatment with Flavine

1 *Cases treated by primary suture*—Wounds treated by excision of the infected and damaged tissue followed by primary suture gave excellent results In a series of 30 wounds of this kind only two broke down. In a test such as this it may be well to give brief details of the two unsuccessful cases

CASE A.—A fragment of shell passed through the thigh from side to side fracturing the femur and causing much comminution of the bone At the operation four and a half hours after the injury many completely detached fragments of bone were removed, along with much damaged muscle The wounds were then thoroughly washed out with 1 in 1000 flavine solution and completely closed up on each side of the thigh with silkworm gut On the second day after the operation the patient looked ill and was febrile On examination the wounded thigh was swollen and the skin showed a patch of discoloration near the wound A second operation was thereupon performed, the sutures on the outer side of the thigh being released, allowing a quantity of brownish fluid, which contained abundant anaerobic bacilli, to escape Four Carrel tubes were inserted into various parts of the wound and six hourly irrigation with flavine was commenced No spreading gas gangrene developed and the subsequent course of this case was uneventful

CASE B —This was a case of severe multiple wounds of the left thigh and buttock There was an entry wound 2 inches above the natal fold, close to the ischio-rectal fossa on the left side, but no exit wound. At operation the missile was seen to have tracked downwards into the thigh The popliteal space was swollen and on making incision the missile, a fragment of shell of considerable size and embedded in cloth was removed. The track of the missile was laid open in its whole course down the thigh, revealing much damage to the hamstring muscles All possible damaged muscle was resected and after washing well with 1 in 1000 flavine the wound was completely sutured without drainage Three days later the wound gave way in its middle third and grumous fluid containing many organisms escaped Under an anæsthetic the wound was widely opened up in its middle third, to show areas of necrotic muscle which had been left behind at the first operation. Free drainage was ensured and the patient was able to be evacuated to the base a few days later, doing well.

In contrast to these two unsuccessful results, one of the 28 successes may be quoted to show in what variety of wounds primary suture was possible.

CASE C —A soldier was admitted with a severe shell wound of the right buttock The entrance wound was near the sacrum and the exit below and behind the great trochanter The track measured 8 inches from end to end At the operation six hours after injury, the track was found to pass through the fibres of the gluteus maximus in all its extent The track was laid open, and several fragments of cloth with much damaged muscle, were removed After arresting hæmorrhage the wound was washed with 1 in 1000 flavine and completely sutured The wound was dressed on the third day and was perfectly sound. The patient was evacuated to the base at the end of a week, sent to England on the ninth day and after removal of the stitches on the thirteenth day was able to walk about

This case is especially interesting, as such wounds of the buttock often develop gas gangrene. The fragments of cloth and pieces of damaged muscle removed at operation were both infected with anaerobic bacilli.

2. *Cases treated by drainage followed by secondary suture*—Secondary suture gave good results in all the 10 cases in which it was adopted. It may be remarked here that in several instances the secondary suture was completed while the wounds were far from being bacteriologically sterile but no untoward result followed. The edges of the skin, however in wounds which have at first been left open and stitched up later do not heal as in primary suture Healing takes place more slowly and a considerable induration can always be felt along the track of the wounds The stitches, moreover must be kept in position much longer than usual and we have found that if they are removed before about the fourteenth day the edges are liable to give way

3 *Open wounds treated with flavine*—In this group are included both wounds treated by the Carrel method and those simply packed with gauze soaked in the antiseptic In open wounds which form the major portion of our series, observations on the rate of healing and on the bacterial flora have been most readily carried out and they have therefore received considerable attention The typical progress of an open wound treated either by the Carrel method or by the gauze packing may now be described, taking as a concrete example a flesh wound of the thigh where a considerable area of skin and muscle have been blown away so that the wound was left open to granulate. On removal of the first dressing on the third day the wound, except for being deeply stained with flavine, has undergone no alteration in its appearance whatever, and resembles an injury only a few hours old. All signs of inflammation are wanting and there is no pain, redness swelling or induration in the tissues around The secretion from the wound is minimal in amount and suppuration is absent The complete absence of suppuration, even

in wounds where films show abundant organisms to be present, is a very noteworthy feature in wounds under treatment with flavine When dressed again at the end of a week the skin edges are found clean cut, no epithelial growth having taken place from the edges The floor of the wound has by this time become covered by a closely adherent membrane, only detached with difficulty from the underlying structures This yellow pellicle forms over whatever tissue is exposed in the wound, whether it be muscle or subcutaneous fat Its histological structure will be referred to later The wound from this time onward, if flavine be continued, remains in a stationary dried up condition, showing neither signs of inflammation nor of repair Even after a fortnight or more only small and scanty granulations can be discovered by peeling off the membrane which covers them

It is obviously improper treatment to continue the application of flavine until such a stage is reached and experience has shown that a wound heals with much greater rapidity if the flavine be stopped after three or four days in the case of small wounds, and after about a week in the case of severe wounds or compound fracture If at this period eusol be substituted the yellow membrane comes away piecemeal within a day or two, and granulations appear more luxuriantly In a very few days later growth of epithelium is well established at the edges of the wound The wound in short, changes its character entirely Abundant discharge of purulent nature, containing always a great number of organisms makes its appearance, and rapid healing occurs

4 *Wounds of the chest, abdomen head and joints* —These cases have formed such a small part of our series that no conclusions of value for this report can be drawn from them It is of interest, however to note that quite considerable quantities of flavine solution can be left in the abdominal or thoracic cavities without inducing the least toxic effect

Histology of Wounds Treated with Flavine

Portions of tissue have been removed from the edges or floor of seven open wounds under treatment with flavine and examined histologically These examinations were made 2, 2½ 3, 8 8 and 11 days after treatment had begun

Up to three days the skin edges were sharply cut and unaltered histologically The floor of the wounds showed a thin layer of fibre and polymorphonuclear leucocytes, covering a narrow zone of necrosed muscle fibres Between the dead fibres polymorphonuclear leucocytes were fairly abundant and in one case many large Gram positive bacilli of the usual anaerobic type were present in the same situation and within the necrotic fibres themselves

The material taken from a wound five days old showed a thicker covering layer of fibrin and leucocytes, with a few dead muscle fibres, embedded in it This layer, which is bright yellow in colour before fixation, is obviously from its structure composed chiefly of fibrin, although it does not give perfectly the characteristic reaction with Weigert's stain No evidence of granulation tissue production was observed, and the skin at the edge showed no epithelial proliferation

The tissue from two cases taken on the eighth day gave information of considerable interest In one case wedges of skin and subcutaneous tissue were removed from open wounds on the abdominal wall and on the forearm, in which muscular tissue was involved Both of these wounds were in a dried up condition, and showed to the naked eye no signs of inflammation or repair This was borne out under the microscope, epithelial proliferation from the edges of the skin being minimal in amount The floor of the wounds was covered by the usual membrane of fibrin and leucocytes, and in one wound there was distinct evidence of early granulation tissue production in subcutaneous fat In the other case a portion of the vastus externus muscle exposed in a large wound of the thigh communicating with a compound fracture, was removed for examination The whole floor of this wound was covered with a very dense yellow membrane firmly adherent to the deeper structures In the segment removed for examination this membrane was 2 millimetres in thickness It was also noted that the subcutaneous fat underlying the membrane at one part of the wound had been stained bright yellow by the antiseptic dye while the muscle remained unaffected Below the membrane in this case granulation tissue production was evident throughout, forming a comparatively thin layer The edge of the skin in this wound was examined

The tissue taken from the wound eleven days old showed no new features Granulation tissue production was well established below the yellow pellicle, but there was little epithelial ingrowth from the edges of the wound

Bacteriology of the Wounds

Except in the cases where primary suture was adopted most of the wounds were examined from day to day As a routine films were made and stained by Gram's method and both aerobic and anaerobic cultures were set up to amplify and control the observations in films In this way a fairly complete examination of 90 wounds has been made.

A small number of the wounds remained sterile from the outset These were cases in which it had been possible to remove all damaged and infected tissue at the time of operation, and all of these wounds were soon closed by secondary suture It may be said at once, however, that in the great majority of the wounds no sterilisation in the bacteriological sense was brought about by the application of flavine The wounds tended to pass through as regards their bacterial flora the stages now well recognised in wounds of this war Infection by anaerobic bacilli was very common in the early stages, but tended to pass off at the end of about a week, except in the case of compound fractures, where the infection generally continued as long as the wounds remained under observation After a few days invasion of the wounds by streptococci was almost the rule, accompanying, and often gradually replacing, the anaerobic infection Later, generally after a week or longer, infection with a variety of other organisms was commonly met with, especially staphylococci, *B pyocyaneus*, and a variety of short coliform bacilli The coliform bacilli require special notice because of their frequency and also because of their marked resistance to flavine, as borne out by test-tube experiments (*vide infra*)

The broad conclusion arrived at from the bacteriological observations was that the type of infection in wounds treated with flavine in no way differed from that met with in cases where other treatments had been employed

A point brought out incidentally was the fundamental difference between what may be termed "surgically sterile" as distinct from "bacteriologically sterile" wounds Complete bacteriological sterility was rarely obtained, yet the patients were obviously doing well and the wounds showed no signs of local or spreading inflammation In several instances secondary suture was adopted with complete success while numbers of organisms were still recognisable in the field of the microscope Cultures moreover, showed that these organisms were still viable

"*In vitro*" *Experiments with Flavine*

A few test tube experiments, using various organisms freshly isolated in culture from wounds in our series have been carried out by Captain J Shaw Dunn, R A M C, to control these done elsewhere The tests were made in tubes containing 4 5 c c of glucose broth and 0 5 c c of varying dilutions of flavine Each tube was inoculated with 0 1 c c of a 24 hours glucose broth culture of the organism under examination This technique, with minor modifications, served for the examination of both aerobic and anaerobic organisms The following results were obtained —

1 *Staphylococcus aureus* —Vigorous growth in tube containing 1 in 80 000 flavine No living organisms in tube containing 1 in 10 000 flavine

2 *Streptococcus pyogenes* —No visible growth in tube containing 1 in 100 000 flavine No living organisms in tube containing 1 in 100 000 flavine

3 *Streptococcus fæcalis* —Visible growth in tube containing 1 in 100 000 flavine No living organisms in tube containing 1 in 50 000 flavine

4 *B perfringens* two strains The same technique was adopted here as in the other tests except that the tubes were incubated in an "anaerobic can" in the absence of oxygen Vigorous growth in tube containing 1 in 200 000 flavine No living organisms in tube containing 1 in 100 000 flavine

5 *Coliform bacilli* four similar strains from different cases Vigorous growth in tube containing 1 in 400 flavine Living organisms recovered from tube containing 1 in 100 flavine

A second series of tests in which the dilutions of flavine were made in fresh human serum, were carried out with one strain of a coliform bacillus The technique was briefly as follows —

0·45 c c of fresh unheated human serum was placed in each of a series of small tubes, and 0·05 c c of varying dilutions of flavine were added, so as to give final dilutions in the serum of 1 in 100 up to 1 in 80,000 To each tube was then added 0 025 c c of a 24 hours' glucose broth culture of the bacillus The tubes were then incubated for 24 hours, at the end of which time the organism had grown abundantly in a control tube containing serum alone

Result Vigorous growth in the 1 in 20,000 dilution in serum, no living organisms recovered by subculture from the dilution of 1 in 8000 in serum

This set of experiments bears out the enhancing power of serum on the action of flavine and also shows that of all the organisms tested coliform bacilli are the most resistant to the action of the antiseptic

A further test was made to ascertain whether the enhancing power of serum on flavine was lasting or the reverse

Five small tubes, each containing 0 45 c c of fresh human serum, were made up to 0 5 c c with flavine, so as to give a dilution in each tube of 1 in 5000 flavine These tubes were inoculated with a coliform bacillus at varying intervals up to 90 hours after the flavine and serum were mixed together Subcultures were made from each tube 24 hours after the culture of the organism had been added No growth was obtained in any of the tubes, showing that the mixture of flavine and serum had retained its antiseptic power for at least 90 hours

Conclusions

1. Flavine appears to have many advantages as a *primary* treatment of recent war wounds Among the advantages are —(*a*) The absence of all toxicity, even in large wounds (*b*) The prevention of suppuration and of spreading sepsis, as brought out in our series of test cases (*c*) The primary dressing need not be changed for two or three days, and is then easily and painlessly removed This may be of great advantage during severe fighting where rapid evacuation of wounded from front to base is required without unnecessary dressing of the wounds (*d*) The wounds are not inflamed or painful, and the surrounding skin is never irritated

2. Emphasis must be laid on the fact that excision of damaged tissue and mechanical cleaning of the wound are necessary preliminaries to the use of flavine

3 Flavine cannot be classed as a success in the treatment of the *later stages* of war wounds The wounds tend to assume a stagnant condition, during which the processes of repair are almost in abeyance After a few days when the danger of gas gangrene and of spreading sepsis have to a great extent passed off, flavine should be stopped and another treatment adopted.

4 In the majority of cases war wounds are not rendered bacteriologically sterile even by the prolonged use of flavine

5 Test-tube experiments carried out with organisms isolated from actual wounds bear out the strong antiseptic properties of flavine, and their enhancement in the presence of serum Coliform bacilli, which are a common infection in the later stages of wounds, are much more resistant to the action of the antiseptic in test-tube experiments than any of the other types of organism examined in this way

ETHER-OIL ANÆSTHESIA BY THE RECTUM

BY H M PAGE, F R C S ENG,
ANÆSTHETIST TO THE KING GEORGE HOSPITAL, GUY'S AND THE WEST LONDON HOSPITALS

With a Note by

G B MOWER WHITE, M B, M S LOND, F R C S ENG,
SURGEON TO THE KING GEORGE HOSPITAL, GREAT NORTHERN CENTRAL HOSPITAL, ETC

WE owe this method of producing anæsthesia to Dr James T Gwathmey,[1] of New York Before the beginning of the war I had anæsthetised a good many cases by this method and had come to rely on it entirely for operations on the thyroid gland if hyperthyroidism was present Since 1914 I have used it for the wounded in cases of plastic face and jaw operations Some fatalities have occurred in this particular class of case under the ordinary methods of anæsthesia I therefore suggest the more frequent use of Gwathmey's method, which is simple, easy, and, I believe, safe

Description of Method

The apparatus required is very simple An indiarubber catheter, a funnel a medicine measure, an empty medicine bottle with a cork, to shake the mixture in—this shaking must be done forcibly for two minutes The following is the technique I employ —

A simple wash-out of the bowel an hour or two before the injection, in addition to the usual preliminary dose of medicine, is an advantage, but can be dispensed with if necessary A subcutaneous injection of morphia gr ¼, atropine gr 1/100, is given half an hour before the time fixed for the ether-oil injection I have used the paraldehyde rectal injections, but prefer morphia subcutaneously From 20 to 25 minutes before the time of operation 6 ounces of a mixture containing two parts of ether to one of oil (ether 4 ounces, oil 2 ounces) are slowly run into the rectum Six minutes are spent in making this injection The india rubber catheter is passed 3 or 4 inches into the rectum, never more than 4 inches

When the operation is finished the remaining ether-oil must be washed out, using a large rectal tube and funnel The wash out must be done thoroughly and methodically, as on this depends the rapidity with which the patient recovers consciousness I do the washing out, unless I have shown a nurse how to do it The tube is gradually passed up and as much as possible of the remaining ether-oil mixture withdrawn The tube is then drawn down again near the anus, and some water or saline is run in and siphoned off This is repeated gradually higher up the bowel until no oil or ether can be detected in the returning fluid, when the tube is gradually withdrawn lower and 3 ounces of olive oil are passed in and left there The temperature of the water or saline must not be above that of the rectum—in fact, only the chill off

Following the use of this technique there have been no rectal, pulmonary, or gastric sequelæ The return of consciousness is not delayed when the washing out is done satisfactorily

Soldiers, unless they are very ill, are resistant to the effects of ether, and there is also the loss of ether in the breath, from the venous blood as it passes through the lungs, so that to procure a full anæsthesia in a reasonable time it is often necessary to administer a little ether with a Clover's apparatus and allow some re breathing, if preferred, ether by the open method or some A C E can be given If it has not been possible to give the injection 20 minutes before the time for operating some anæsthetic vapour by the mouth will certainly be necessary for induction to prevent delay After surgical anæsthesia has been produced nothing more will be required by the mouth in a large number of cases The anæsthesia obtained is quiet and even and the laryngeal reflex is present In some cases an occasional whiff of chloroform must be given in the usual way with a Junker's apparatus but of course much less chloroform is required than with the usual methods, and there is the continual even stimulation from the ether absorbed from the rectum, so that with ordinary care there is practically no increased danger

---

[1] THE LANCET 1913, i. 1756

Cases in which the Method has been Employed

I have used this method in face, mouth, and nasal operations 17 times, they all made uninterrupted recoveries, and there were no rectal or other sequelæ This is not a large number of cases in itself, but I have used ether oil rectal anæsthesia in 47 cases altogether The operations in which I have used this method are as follows Plastic operations on the face, operations on the jaw, radical cure of antral disease, œsophagoscopy, bronchoscopy, laryngoscopy, removal of nasal septum, cholecystotomy, cholecystectomy, gastrostomy, gastroenterostomy with partial gastrectomy, exophthalmic goitre, laminectomy, trephining, appendicectomy, amputation of the breast

All these 45 cases recovered from the operation except 2 These 2 cases were laminectomies, they died some time after the operation from ascending myelitis In 2 of my early cases, in which a 75 per cent solution of ether was used, there were rectal irritation, mucus, and a slight trace of blood lasting a day or two In another case there was looseness of the bowel for a couple of days, since then I have never used a stronger solution than 2 to 1, as recommended above

One of the cases of appendicectomy was in a lady aged 75 She had lately suffered from influenza with pulmonary complications, her heart was weak and dilated Acute appendicitis—appendicectomy—uninterrupted recovery

Another, a boy, aged 11, with perforated appendix. Appendicectomy I gave him 5 ounces of equal parts of ether and olive oil He made an uninterrupted recovery

The patient in one case of amputation of the breast was a big, very fat, elderly woman She was suffering from asthma and chronic bronchitis The complete operation was done Recovery was uninterrupted There was no effect whatever on her pulmonary condition

I should say that post-anæsthetic vomiting is less frequent than with other methods Pain is not complained of during injection when a 2 to 1 solution is used I do not know if it would be safe to put the patient into the Trendelenburg position when using this method I have never done so, and I have not seen any reference to this position in the American literature on the subject Mr Mower White, who operated in the majority of the plastic cases, has kindly added the following note

Note by MR MOWER WHITE

Mr Page has asked me to add a few remarks to what he has written concerning the administration of ether per rectum I have seen this form of anæsthesia used in a considerable number of cases and for many different operations All the patients have been adults The results have been uniformly good both as regards the condition of the patient during the operation and as regards the absence of untoward symptoms afterwards

In operations upon the face and mouth, to which Mr Page refers, there can be no doubt that ether administered per rectum is a far safer anæsthetic than is chloroform vapour by inhalation Certainly in those cases upon which I have operated we have not had a moment's anxiety with regard to the condition of the patient, while at the same time the degree of anæsthesia has been sufficient for all that was required In these operations, too, the absence of apparatus for delivering an anæsthetic confers greater freedom upon the actions of the surgeon and is a welcome relief Most of the operations have occupied an hour, some even an hour and a half, and the anæsthesia has remained good until the end. Many of the patients were sick once after the operation but I have seen no case of repeated vomiting

As regards the rectum, no trouble has arisen in any of my patients, and there has been no evidence of irritation of the rectal or colic mucous membrane I attribute this absence of symptoms to the fact that a very thorough washing out of the bowel has been practised as soon as possible after the operation is finished The lavage is continued until the water returns almost clear certainly free from the odour of ether and from visible globules of oil

In a few instances I have recommended this mode of anæsthesia for patients suffering from chronic bronchitis and needing operations These patients took the anæsthetic well and were none the worse for it

A CARTILAGE PROSTHESIS FOR THE EYE

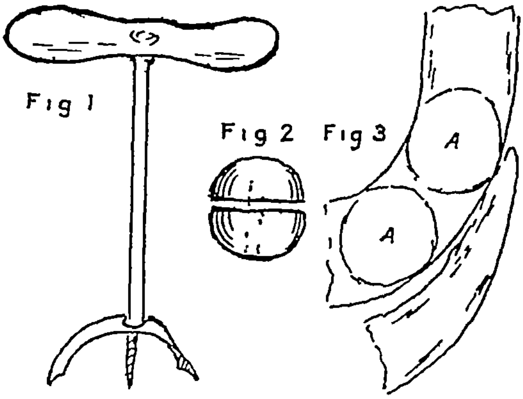
BY J L AYMARD, M R C S, L R.C P LOND,
CAPTAIN, R A M C (TEMP) QUEEN'S HOSPITAL FOR FACIAL INJURIES FROGNAL, SIDCUP KENT

THE failure of the artificial eye from a cosmetic point of view depends upon two main factors, immobility and depression The former condition is due to the absence of a mass of tissue fitting inside the artificial glass casing and the latter to the fact that a sphere has been replaced by a shell

However much ophthalmic surgeons may differ as to the value of metal or glass prosthetic globes, plastic surgeons in general would, I feel confident, agree with me that there can be no question as to the superiority of the use of natural tissues With this object in view, I am now employing spheres constructed from the costal cartilage

Since my investigations regarding the vascularity of cartilage I can, with the utmost confidence, understand how cartilage transferred rapidly establishes fresh communications with the blood-vessels in its new vicinity and becomes fixed *to the capsule in a recent enucleation or to the surrounding* tissues in older standing cases

Fig 3 illustrates the portion, A A, of the eighth costal cartilage from which two hemispheres are trephined. These (Fig 2) are then either pegged with cartilage or fixed with catgut.



In primary enucleations, provided there is no sepsis the surgeon places the cartilage sphere *inside* Tenon's capsule and sutures the same He then proceeds to suture the conjunctiva Whilst the ophthalmic surgeon is enucleating the eye the second surgeon can, with practice, produce the sphere of cartilage

Whether cartilage spheres can be introduced into a septic eye socket or not remains to be seen, but from experience in other directions I am inclined to think that it is worthy of extensive trial as the resisting power of cartilage to sepsis in nasal cases is remarkable

Fig 1 gives a diagrammatic view of the trephine I use The object of this trephine is not only to cut each hemisphere circular but to shape it at the same time *The* two points of the trephine have cutting edges each made to cut in the same direction, the central pin is fixed and gimlet-shaped

MEDICAL SOCIETY OF LONDON

Modern Artificial Limbs and their Influence upon Methods of Amputation

A MEETING of this society was held on Oct 22nd, Sir StClair Thomson, the President, being in the chair

Mr E Muirhead Little and Major R C Elmslie, R A.M C, introduced a discussion on Modern Artificial Limbs and their Influence upon Methods of Amputation

Major Elmslie said that when the hospital for fitting artificial limbs was started at Roehampton in the summer of 1915 the supply was inadequate and the types available were by no means perfect , The limbs demonstrated represented a series of typical examples of the work at Roehampton The arms represented an immense mechanical advance upon the very elementary types which were available at the beginning of the war The function of an artificial leg was to give good stability in standing and walking and a natural gait Hence the important points were the way in which weight was borne upon the leg, the way in which the leg was built to secure stability, and the way in which the knee and ankle were controlled A stump might take its bearing either upon its termination (end bearing) or upon the bony prominences around the proximal joint In general, end bearing either complete or partial might be expected when the bone section was through cancellous bone, when the bone was covered with thick skin and muscle or fascia, and when the skin over the stump was itself naturally adapted to weight-bearing The type of end bearing stump was, of course, that given by Syme's amputation The other bearings used should be those upon the tuberosity of the ischium and upon the head of the tibia Although a certain amount of bearing might be taken by fitting the stump tightly and so getting circumferential pressure upon it, yet this must not be trusted to any great extent, as by this method the skin was apt to be stretched tightly over the end of the stump and if the scar was terminal or the skin thin this might result in ulceration Major Elmslie then described the points in the fitting of a limb for amputation through the thigh This limb was generally suspended by a sling over the shoulders the lower end of which was attached to the leg below the knee, either directly or by passing over a pulley In this way it acted as a knee-extending mechanism In short stumps however a pelvic band was necessary to enable the stump to remain securely in the bucket and to control the limb The mechanism used to extend the knee was of two sorts The older one was a spring, either of rubber or of steel, which should act in such a way that the knee was only extended by it from the right-angled position If it acted from a position of greater flexion than this it would prevent the man from sitting comfortably with a flexed knee The second method was the sling from the shoulders which pulled upon the front of the leg piece when the shoulders were raised or when the weight of the swinging limb was put upon it thus extending the knee. The stops which limited the movement of the knee in both directions must be so strong as to be unbreakable even when the whole weight of the body exerted its maximum leverage upon them In the ankle mechanism the present limbs almost all differed from the Anglesey leg in that the movement allowed at the ankle joint was small in range (only about 20 to 30°) and this movement was stopped by the compression of springs, usually of rubber but sometimes of steel The small range of movement was found not to interfere with walking Correct building of the limb was essential if stability was to be secured Two points were essential (1) The axis of the knee-joint must be behind the line which represented the centre of gravity of the body when it was erect and (2) the foot must be mounted in slight equinus (20°) and must be prevented from reaching the right-angled position The routine material for the construction of artificial legs was still willow and as a rule the thigh and leg pieces were constructed of single pieces of wood appropriately hollowed out the joints being made of steel It was not an advantage to have very lax joints in an artificial leg As a rule the joints were lined with a bushing of leather, by adjusting which they could be made stiffer Hip-joint amputations were fitted with a leather cup which entirely enclosed the stump fitting it very accurately This was attached to the trunk by a steel pelvic band, and to it was attached the limb, by a hinge joint on the outer side and on the inner side by a steel piece which runs around on a quadrant situated upon the under surface of the leather cup It was possible by placing the hip-joint far forward and the knee-joint far back to fit a limb which was stable with both hip and knee joints free, but it was customary to fit locks to both these joints, so that the man might walk with one or other free In amputations through the knee the lower end of the stump was larger than the part higher up, therefore the front of the bucket must be cut away and filled in by a piece of leather or else an entire leather thigh-piece must be used In either case the leg piece was attached by outside steel joints For amputations below the knee a wooden bucket was accurately fitted to the head of the tibia and below the patella The weight should be borne upon these points, although in exceptional cases it might be necessary to fit a leather thigh bucket reaching right up to the tuberosity of the ischium and taking a bearing there In short stumps a partial end bearing could often be taken by stretching a shelf across the bucket at the right level In some cases it was difficult to stop the stump rubbing up and down in the bucket during movement at the knee joint, but this could be got over by fixing a leather socket closely to the stump and inserting this into the bucket As a rule the leg was suspended around the thigh by a leather corset with lateral steels hinged at the knee When a man had worn a leg for some time, however he could often dispense with this, having the leg attached only by a narrow band of leather fastening above the knee, to which the leg was hung by lateral straps If this was done the foot should not be adjusted with too much equinus, as the equinus position of the foot tended to force the knee into a hyperextended position A Syme stump was fitted into a leather bucket strengthened with steels on either side and in front and preferably lacing behind The ankle joint worked against two rubber buffers as in the other types of leg It was possible however to replace this mechanism by a tendon stop at the back and an anterior accumulator and this method must be used in Pirogoff and Chopart stumps Many other materials besides willow were now being tried, such as leather, plied wood, wood shavings and glue, celluloid and duralumin A type of leg for a thigh amputation which would not give way under the weight of the body when the knee was flexed, had been recently invented but was still on its trial In general an artificial arm should be designed to take the place of the left arm in work and must be adapted to the particular needs of the man. Movements could be transmitted to it by tension being put upon cords In this way three pulls could be exerted (1) by expansion of the chest, (2) by rounding the shoulders, (3) by elevation of the shoulder These cords could be used to activate the elbow joint to lock and unlock this joint, and to work a mechanical hand or appliance used in its place An arm for amputation above the elbow should be attached by a harness which passed over the shoulder but this should limit the shoulder movements as little as possible The arm and forearm parts should be connected at the elbow by a hinge joint with a lock, which fixed it securely and prevented movement in either direction The alignment of the elbow joint need not be the true one as it was more useful for it to flex more across the chest In *the mechanical arm* the elbow was flexed by a cord usually activated by the pull given by rounding the shoulders In this arm the forearm piece had the shape of the natural arm and ended in a wrist plate to which the hand or other appliance could be attached In a *worker's arm* the forearm was represented by a skeleton of steel, usually a rod to which appliances could be attached If a man who had such an arm for work wished to have a nice looking forearm and hand he could adjust a show piece representing these over the skeleton These two types of arm the mechanical and the worker's could be combined by making the elbow mechanical but using a skeleton forearm For amputations below the elbow a simple socket was used connected to an arm corset by lateral steel joints, or in the case of long stumps by lateral leather straps In a new arm made by Williams of Swansea the elbow was kept permanently slightly flexed the socket was fitted to the forearm stump and held on by a continuation upwards of firm leather which laced around the condyles of the humerus, giving a very secure hold for a working arm In wrist amputations and other amputations low down in the forearm it was important to preserve the movements of pronation and supination It might be possible to do this by omitting the steel joints at the elbow, or the movement could be secured by the pronation arm made by Hobbs, in which ball and socket joints allowed the forearm socket to rotate upon the elbow For working men appliances fitted to the wrist-plate were generally more useful than a hand The number of appliances made might be divided into the following classes (1) Simple hooks, rings, and grips, without movement, (2) similar appliances in which there is mobility in one or more directions representing wrist movements, (3) grips opened or closed by the pull of a cord from the shoulder Many of the appliances invented by Adams, Hobbs, and Anderson would be seen on the arms worn by the men present The hand was not so useful in mechanical work as the appliance, but for men in professional work a good hand was an essential In most cases the hand supplied was a simple one, with a spring grip to the thumb and often with the ring and little fingers curved into a hook and reinforced for carrying But mechanical hands were possible and useful for certain men The first essential in a mechanical hand was that the grip should not be a simple spring grip, which would always be forced by a very slight leverage from without, the mechanism should be such as could not be forced except by breaking the hand Such a mechanism had been invented in a very simple and light form by Hobbs, and adapted to a number of different shaped hands In order that the hands or appliances might be removed at will and replaced by others it was essential that they should all be detachable, and for quick detachability the screw method was being replaced by others In addition to the makers named above the following had examples of their limbs at the demonstration Messrs Rowley, Hanger and the Essential Limb Co, for lower limbs, and Messrs Blatchford for arms

Mr **MUIRHEAD LITTLE** said that the chief duties of the lower extremity were to support the weight of the body at rest and in motion, and to act as the propellent force in the process of locomotion End pressure and leverage were the strains to which it was most exposed The upper extremity was mostly employed in prehension and traction—functions to which the foot of boot-wearing man was a stranger, and end pressure therefore was not one of the most important strains to which it was exposed while leverage was all important. In both the upper and lower extremities provision had to be made to maintain the appliance in place when in action and also, when at rest, against the action of gravity Weight was borne *(a)* by direct pressure of a part of the body downwards, such as the end of the stump or of a convenient bony process, such as the tuberosity of the ischium, or *(b)* by oblique pressure, when the artificial socket formed a more or less conical cavity into which a conical portion of the body fitted. These two were often generally combined Leverage was exerted by the lateral surface of the stump pressing against the side of the surrounding socket An ideal amputation stump should be as long as possible, it should be covered by sound, moveable, soft parts, and the scar should be placed in a position where it would not be exposed to pressure, and it also should not be adherent to the bone It should have enough muscles attached to it to move it with adequate force and no inflamed or hypersensitive nerve ends should be palpable in it The end or ends of the bone or bones should be rounded so as not to hurt the soft parts under them and the blood supply should be free and the skin well nourished Consideration and experience of modern artificial limbs led to the conclusion that except in the cases of the hip and shoulder, exarticulations were to be avoided, and that amputation through the limb segment above the joint was to be preferred In the lower extremity a stump capable of bearing some at least of the body-weight on its end should be aimed at Every pound of pressure here meant less pressure on other parts, which in some cases did not bear it well An analysis of the records of 549 cases of amputation of the lower extremity seen recently at Roehampton showed that the stumps in the lower third of the thigh are much more sound than those in the upper and middle thirds which latter region was the seat of nearly half of the total number (43 per cent) In the upper extremity the question of end pressure did not arise and here the condition of the lower part of the anterior and external surfaces of the stump was of most importance, because these surfaces had to take much of the pressure of the leverage action on the bucket Many arm stumps with large adherent guillotine scars covering the end of the bone had been found to be quite satisfactory in practice The presence of osteophytes was rarely any hindrance These were seldom large except in the thigh and then they were usually situated about the femoral insertions of the adductor muscles which were not exposed to much pressure The different sites of amputations called for special consideration Speaking of the upper extremity he said that a forequarter amputation gave no choice of flaps The resulting scars would generally bear a properly moulded shoulder cap and an artificial arm with some movements. In exarticulation at the shoulder the lines of scar should avoid the clavicle and the prominent bony ridges of the acromion &c, for on these the shoulder cap must press Amputations in the upper third of the arm offered very little hold for the socket of an artificial limb Owing to the arrangement of the muscular attachments around the joint the upper three inches of humerus or even more, were unavailable and as in the arm of average length the upper third was only a little over four inches long, very little was available even in an amputation at the junction of the upper and middle thirds A good deal could be gained by removing wholly or in part the folds of the axilla—i e the pectoralis major and the teres major This had been done with good result and seemed to be an operation worth doing in suitable cases The latissimus dorsi had not been interfered with so far as he knew It was less in the way than the other two muscles A gain of one inch of stump here was of the very greatest value and as large adherent scars covering the end of the bone were comparatively unobjectionable in the arm, the surgeon in amputating above the middle of the shaft of the humerus should save as much bone as possible even though there might not be skin enough to cover it completely The drag upon the adherent scar which gave trouble in the lower extremity is seldom complained of in the upper owing to the absence of much upward thrust The objections to amputations through joints in general applied to the elbow in particular force owing to the shape of the bones If it was impossible to get a forearm stump extending at least an inch and a half below the insertions of the tendon of the biceps amputation above the condyles of the humerus was to be preferred The action of the biceps tendon which tended to throw off the bucket when it contracted in flexion was one of the chief difficulties in these short-forearm stumps Unfortunately, this tendon could not be spared and its removal was out of the question The remains of the bellies of the flexor muscles, however, were of no use and had been removed in some cases with more or less advantage enabling a better grip on the stump to be obtained The middle third of the forearm gave good stumps but the lower third was not a favourable site Many stumps were cold and cyanotic and the skin tightly stretched and adherent Moreover, the ends of the bones were often tightly soldered together by fibrous tissue or even bone, and the movements of pronation and supination were lost Below the wrist it was worth while to save the carpus and base of the metacarpus if possible, provided movement was preserved The short stump thus formed could be used to actuate a movable thumb with considerable force by means of a simple appliance If one active finger or a thumb were left it was easy to fit a stump to which it could be opposed, and thus to give the picking up action and the power of holding a pen In the lower extremity he considered that exarticulation or amputation through the neck of the femur was better than amputation in the upper third of the thigh The short stump was unable to move the lever formed by the thigh bucket with sufficient force no matter how light the limb might be Such improvements had been made in fitting what was rather inaptly called a *tilting table* that patients who had tried both the ordinary thigh bucket and this appliance usually declared that the latter was much the best The middle third was the site of nearly half the amputations of the lower extremity treated recently at Roehampton In this region the objects aimed at should be a non adherent scar behind the bone and a good disposition of the muscular masses on the inner side If the great adductor muscles were allowed to retract too much a too conical stump resulted, and the bunch of soft parts at the top of the thigh just below the pubes formed a serious obstacle to the fitting of a socket. The tendons and fasciæ should therefore be sutured if possible over, but at least near to the end of the bone. The lower third of the thigh, just above the condyles, offered the best thigh stump for fitting with an artificial limb If a long anterior flap was made even though there might be an adherent scar behind the bone, a good end bearing stump often resulted If the patella could be securely fixed to the end of the bone so much the better The general objections to exarticulations applied to the knee joint In the leg below the knee the most favourable site was the lower part of the middle third With skilled fitting however even very short stumps were useful Amputation in the lower third of the leg seldom gave a satisfactory stump The bone surface at the end was too small for good weight-bearing, and the skin was often badly nourished cold, and cyanotic. Syme's amputation was deserving of its great reputation If properly done it gave a painless weight bearing stump The bones should be sawn through well above the internal malleolus so as to avoid too bulbous a stump, and care should be taken to make the section at right angles to the long axis of the whole leg and not at right angles to the often incurved lower fourth, otherwise a varus stump was likely to result Too low a section left no room for a strong transverse ankle-joint and a too voluminous heel flap meant an unsightly artificial foot and boot Of Pirogoff's amputation experience at Roehampton was small and unfavourable If the os calcis was not united to the tibia by bone it would sooner or later tilt over and cause pain and in any case the stump was too long for the fitting of the best type of foot Chopart s amputation gave a good bearing surface but generally the calf muscles pulled up the heel and tilted the lower end downwards, and painful pressure on the scar resulted The stump was too short to give a spring to the gait, and it was well nigh impossible to fix any prolongation on to it

Speaking of operation cases sent over from France, Major JOCELYN SWAN asked whether the speakers considered that the secondary amputation should be performed at once while the limb was still in a septic condition, or whether it should be postponed till healing had taken place

Lieutenant-Colonel D ELCUM I.M S, asked how long an artificial limb would last and whether the parts of a limb which were worn out could be renewed by anyone except a skilled maker

Mr MUIRHEAD LITTLE said that the secondary amputation should be done as late as possible. An artificial leg would last about seven years but probably something would require to be done in about a year and a half Arms had only been in existence about two years, so it was not known how long they would last Many of the men who came back to Roehampton after six months were those who had used them for very hard work Centres for repair were being started in provincial towns which would save the trouble of coming to London

Major ELMSLIE said that the longest time an arm had been in use was one year He considered that the fitting of an arm was only the first part of the business The man should then be trained to use his arm in a general way and later to make use of it in a special way according to his particular trade or occupation

---

LONDON DERMATOLOGICAL SOCIETY —A meeting of this society was held on Oct. 16th Captain W Griffith the President being in the chair —The President announced that Dr Morgan Dockrell who was the first president of the society had presented a collection of books on dermatology which was to form the nucleus of a permanent library for the use of the society —The opening address of the session was given by Dr Leonard Williams entitled The Real Dermatology '—The following clinical cases were shown —Dr J L Bunch Two cases of Rodent Ulcer, the lesion being situated on the left orbit in the one case and on the left cheek in the other case —Dr Morgan Dockrell A case of Epithelioma supervening on Lupus Erythematosus —Dr W Knowsley Sibley A boy who had suffered with Pityriasis rubra pilaris for seven years and was just developing an attack of Guttated Psoriasis —The President A case of Xanthoma Multiplex also a case of Multiple Lupus in a boy who had exactly 80 distinct lupus nodules present

Diseases of Occupation and Vocational Hygiene Edited by GEORGE M KOBER, M D, LL D, Washington, D C, and WILLIAM C HANSON M D Belmont, Mass Philadelphia P Blakiston s Son and Co 1916 Pp 918 Price $8

ANY contribution to the literature of diseases of occupation is to be welcomed particularly at the present time. The latest addition is the work of many American authors, with contributions by Sir Thomas Oliver and Dr T M Legge, of England, and Professor Dr L Devoto, of Milan The editors Dr George M Kober and Dr William C Hanson in their foreword set out that their aim has been ' the presentation of the basic data concerning the diseases of occupation in such a way as to render them available not only to physicians but also to employers employees, efficiency experts public health officials and legislators " With this object in view the work has been divided into three parts Part I. deals with the Specific and Systemic Diseases of Occupation, Part II with the Causation and Prevention of Occupational Diseases and Accidents, and Part III deals with Statistics and Legislation bearing on Occupational Diseases Each part is divided into chapters and sections, and the references which are numerous and valuable are given at the end of each section Some degree of repetition is inevitable in a work contributed by many authors, several of whom deal with the same subject from a different aspect, but in future editions unnecessary repetitions should be reduced

Part I, which deals with the Specific and Systemic Diseases of Occupation, includes the more common forms of industrial poisoning, such as poisoning by arsenic, brass, lead, mercury &c. Lead poisoning is fully described, but we cannot agree with Dr H. Linenthal who contributes a section on the early diagnosis of lead poisoning, that a history of exposure to lead justifies the diagnosis of lead poisoning in patients presenting obscure symptoms which otherwise cannot be explained We notice that throughout the section on lead poisoning by Sir Thomas Oliver no reference is made to the valuable experiments carried out by Mr Kenneth Goadby as to the effect on animals of ingestion and inhalation respectively of lead dust These experiments show that lead is far more poisonous when inhalaled than when absorbed in any other way a point to which Sir Thomas Oliver omits to draw attention [1] Poisoning by the inorganic gases and diseases of the chemical industry in general are not so fully dealt with as we think this important branch of industry deserves On the other hand, a section is devoted to a rare form of disease—viz., poisoning by manganese Similarly a section describing the effects on health produced by diminished atmosphere in ballooning and aviation by Dr Kober, shows the scope of the work

Systemic occupational diseases are dealt with in two chapters—Chapter I Dust Diseases of the Lungs, by Sir Thomas Oliver, Chapter II Diseases of the Blood, Circulatory System, and Kidneys, by Dr Thomas L S Leigh. There does not seem to us to be much advantage in describing the symptoms pathology, and treatment of diseases such as acute and chronic endocarditis and acute and chronic nephritis in a work of this nature The subjects are treated shortly, and we cannot find that a short epitome of these diseases is of value to the medical reader, who can study the subjects in detail in medical text books To the non professional reader a little knowledge of symptoms and treatment may, we feel, be a source of danger, and this is a treatise which makes a fair appeal to a lay public. Occupational diseases of the Nose, Mouth and Throat, and of the Eye and Skin are dealt with by separate contributors Occupational Diseases and Injuries of the Eye by Dr Würdemann occupy another chapter, and here for example we think that the subject cannot be dealt with at sufficient length to enable the instruction and conclusions to be of practical value For the diagnosis of foreign bodies within the eye Dr Würdemann suggests the use of the giant magnet He states however that this method of examination is somewhat dangerous We entirely agree with this statement and would suggest that such a method can only be safely employed by a skilled ophthalmic surgeon Occupational affections of the skin by Dr Brown, of Boston, considered from the point of view of the various trades and callings, shows the variety of occupations which produce skin affections, and deals with such widely different occupations as housemaids, musicians, and surgeons An attempt to include all who are likely to be affected by skin diseases has, we think, tended to crowd out some workers in the more important industries where such diseases in acute and severe forms are commonly met with Little or no mention is made of dermatitis affecting workers in the nitro derivatives of benzol or toluol A chapter on cancer and occupation is of interest, and includes effects produced by exposure to X rays and radium Part of this chapter is occupied with a brief description of the theories as to the causation of cancer, contagion and house infection, &c We hardly think such a study comes within the scope of the work

---

[1] Lead Poisoning and Lead Absorption Legge and Goadby London 1912.

Part II deals with the Etiology and Prophylaxis of Occupational Diseases and Vocational Hygiene Dr Kober, one of the editors, contributes largely to this part Much of his contribution is in the nature of a résumé on personal hygiene, and again we have a protest to utter against redundancy We do not in any way minimise the value of personal hygiene in the prevention of occupational disease, but the omission of a consideration of this subject on general lines would in no way diminish the value of the essay The subsequent sections of this part deal with the various industries and industrial poisonings, and special accidents attaching to them Much of this is in many instances a repetition of Part I Some contributors briefly outline the various processes of manufacture in which industrial poisoning is to be met A few deal with the special preventive measures applicable to the various industries We notice the brief reference to poisoning by trinitrotoluene and tetrachlorethane In view of the importance which poisoning by these substances has assumed, we feel sure the subject will be more fully dealt with in future editions One section is devoted to the subject of vocational hygiene of the liberal professions, public service employees Several tables, one giving a list of industries and the poisons likely to be met with in each, and a series of mortality and morbidity statistics complete Part II

Part III, the Relation of Hospital and Medical School Work, Statistics Government Study and Legislation to Occupational Diseases, includes an interesting chapter by Professor L Devoto, of Milan, in which he describes the Milan Clinic for Occupational Diseases This should be read by all interested in occupational diseases and should prove an incentive to other countries to follow the lead given by Italy Frederick L Hoffmann, LL D, contributes a chapter on the mortality from pulmonary tuberculosis and dusty occupations The value of this chapter is diminished by the absence of a more definite analysis of the various dusts dealt with, but it contains a valuable lesson by showing the high rate of mortality from pulmonary tuberculosis among workers in dusty industries A chapter on the use and the fallacies of statistics may be of interest and serve as a preliminary study to those who have no knowledge of the subject but who wish to take an intelligent interest therein The remainder of Part III is concerned with legislative measures and the notification of occupational diseases

We congratulate the editors on the result of their work, which is well illustrated throughout

---

Text book of Ophthalmology By Hofrat ERNST FUCHS, Professor of Ophthalmology in the University of Vienna, Authorised translation by ALEXANDER DUANE, M D, Surgeon Emeritus, Knapp Memorial Hospital, New York Fifth edition London and Philadelphia J B Lippincott Company 1917 Pp 1067 Price 30s

IN previous reviews of this work we have always expressed the opinion that it is the best of the larger text-books of ophthalmology In the presence of several excellent competitors it can only retain this proud position by keeping well abreast of the times The new (fifth) edition not only sustains but enhances its high reputation Though Dr Duane is very careful to distinguish his additions to the original by the use of square brackets, they are so ubiquitous that it is difficult to apportion the author's and the translator's contributions A rough estimate indicates that the latter is responsible for nearly half the book In previous editions the joins in the mosaic have been very evident In this edition, in spite of the brackets, the welding is very much more satisfactory Another great improvement consists in changes in the arrangement of the original text The many pages of remarks in fine print, which were formerly massed as an appendix at the end of chapters or major divisions, and whose considerable value and interest were thus obscured, have been split into shorter sections, each placed in direct juxtaposition to the portion of the text to which it relates Considerable additions have been made to the chapters on glaucoma diseases of the retina, and disturbances of motility, and to the sections on refraction, accommodation, and operations Dr Duane's well known interest in ocular paralyses is given perhaps rather too free play, somewhat to the detriment of proper balance On the other hand, some of the chapters on operations might be still further elaborated with advantage Other important additions deal with tuberculin and vaccine therapy, the visual field and colour testing the mapping of scotomata and the blind spot, the etiology of iritis, suppurative choroiditis, retinitis exudativa, and so on

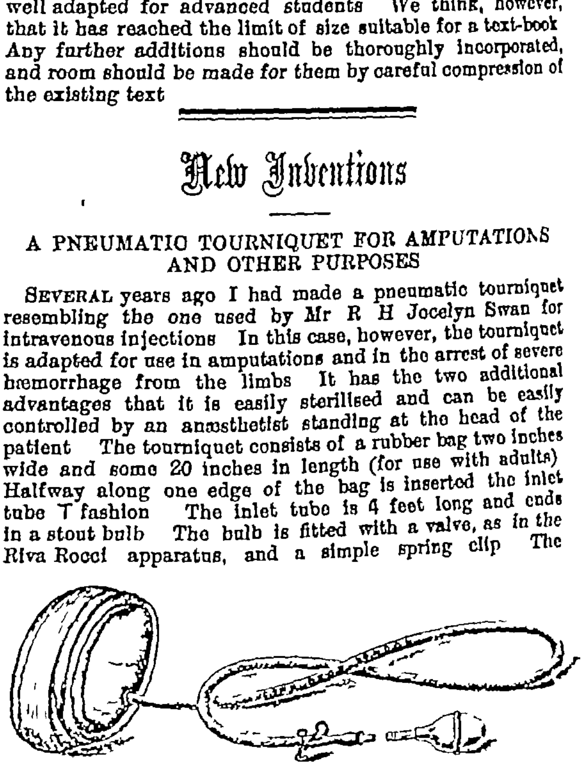
The book is an admirable exposition of the subject and is well adapted for advanced students We think, however, that it has reached the limit of size suitable for a text-book Any further additions should be thoroughly incorporated, and room should be made for them by careful compression of the existing text

---

New Inventions

A PNEUMATIC TOURNIQUET FOR AMPUTATIONS AND OTHER PURPOSES

SEVERAL years ago I had made a pneumatic tourniquet resembling the one used by Mr R H Jocelyn Swan for intravenous injections In this case, however, the tourniquet is adapted for use in amputations and in the arrest of severe hæmorrhage from the limbs It has the two additional advantages that it is easily sterilised and can be easily controlled by an anæsthetist standing at the head of the patient The tourniquet consists of a rubber bag two inches wide and some 20 inches in length (for use with adults) Halfway along one edge of the bag is inserted the inlet tube T fashion The inlet tube is 4 feet long and ends in a stout bulb The bulb is fitted with a valve, as in the Riva Rocci apparatus, and a simple spring clip The bag is fitted in a sterilisable cover and has a lead back to prevent rolling when distended, this improvement being originally suggested by Colonel A Fullerton In use the bag is wrapped round the limb the inlet tube passing towards the head A 2½ inch linen bandage is then firmly applied over the tourniquet and the bag inflated till the distal pulse disappears In the course of an amputation, when all bleeding points have been secured the anæsthetist, by manipulating the valve end, can release the pressure, pumping up again if bleeding recommences In operating on patients with brittle arteries less damage will be done by this tourniquet than by any other, because the pressure is only just sufficient to compress the artery, and can be released immediately the artery is tied This tourniquet should prove useful in the transport of wounded when there is fear of hæmorrhage The bag and bandage can be applied beforehand, the actual inflation being all that is required if the emergency arises In this case one inflates till the bleeding stops a proceeding which could be left to a comparatively inexperienced person



The makers are Messrs. Down Brothers of St Thomas's street, London S E

RELATION OF DEPOSITS	xiv

INTRODUCTION

SINCE the publication of the Committee s first Report for the year 1914–15, some difficulty has been experienced owing to lack of funds It will be remembered by those who have read the Report above referred to that this Committee is a purely voluntary body, relying for funds upon outside support The work falls into two main divisions —

(1) The organisation of the whole scheme, preparing designs of gauges and instructions for their operation as well as for analysis of deposit, collecting, filing, tabulating, discussing and publishing the results, and generally controlling and coördinating the work

(2) The establishment and operation of the gauges, collection and analysis of deposit, and the sending of monthly returns to the Committee

The cost of No (2) is borne by the observing stations, and is a very important item, amounting to about £1000 for the year, without counting the cost of providing and installing the gauges The trouble has been to finance No (1), as it is hardly to be expected that the bodies which bear the cost of No (2) should also bear that of No (1)

In view of the above considerations, application was made to the Department of Scientific and Industrial Research for a Government grant in aid of the work included under No (2), and the Committee have now gratefully to acknowledge the generous help given to them by the Department

Not only have their financial difficulties been met by a substantial grant, but the work has been given official approval and status by placing it under the control of the Meteorological Office The Committee has been constituted an 'Advisory Committee on Atmospheric Pollution to the Meteorological Office, and its original title has been altered accordingly At the same time little change in the personnel has been made, with the exception that the Department of Scientific and Industrial Research have power to appoint a representative, and it has also been decided to ask each coöperating authority to appoint a representative It will thus be seen that a new impetus has been given to the work, and although, strictly speaking, the changes which are above indicated took place during 1917, yet as their effect is retrospective, as above indicated it appeared best to set them forth here

It was originally intended, on receipt of the grant above mentioned, to publish the Reports for 1915–16 and 1916–17 at the same time, as the latter year s returns are practically all in Further consideration indicated the advisability of placing the 1915–16 results before the public at the earliest possible moment, instead of delaying them to incorporate the 1916–17 results in the same Report It was therefore decided to do this but it is hoped that the publication of the third Report will not be delayed more than two or three months behind the present one And future Reports should be made public very shortly after the conclusion of each year s observations on March 31st

The Committee felt that the question of carrying on its work and that of the observing stations during the war required very careful consideration, and, after full discussion, it was decided that it would be inadvisable to stop the work during the war if it could be carried on. In coming to this decision the importance of continuity in the collection of such statistics was kept in mind, as well as the advantages which would arise from having all the data on atmospheric pollution ready by the time peace returned, when people s minds would again find interest in more peaceful problems

The connexion between atmospheric pollution and fuel economy was not lost sight of, and at a time when this is of such vital importance as the present the loss of combustible matter represented by the soot suspended in the air appeared a legitimate subject for investigation.

In considering the subject from the point of view of fuel economy it is interesting to note that, taking the case of the County of London alone for the year 1915–16, and basing the figure upon the average returns from the different observing stations, the total quantity of matter deposited from the air during the year on London was approximately 54,200 tons, and by reference to the figures shown in the tables it will be seen that this deposited matter is, to a great extent, derived from fuel waste in the form of smoke. The six months April to September were responsible for about 24,900 tons, and the six months October to March 29,300 tons. Not only is it necessary at present to scrutinise carefully every source of waste, but it is equally necessary to conserve the health and physical energy of the people. It may not be out of place in this connexion to mention that the approximate quantities of air, solid food, and water required by an adult human being per day are:—

Air	30 lb
Food	2.7 ,,
Water	4.5 ,,

In the first Report, for the year 1914–15, maps were given showing the positions of the deposit gauges for the stations then at work; in the present Report, therefore, these maps have not been reproduced, but in the case of new observing stations not already included in the previous Report maps are now given (pp. xix. and xx.) and the position of each gauge is indicated in a similar way to that adopted in the 1914–15 Report—that is, a black circle 1 inch in diameter is placed upon the map so that its centre coincides with the position of the deposit gauge.

It has been naturally unavoidable that owing to the pressure of other work and the depletion of staffs arising from the war certain stations have found it impossible to continue observations, so that the list of observing stations for the year under consideration will be found considerably curtailed as compared with the preceding year. It may be stated, however, that the cessation of observations is in most cases only temporary, and it is confidently expected that when peace conditions return the work of collecting, analysing, and reporting the results will be again resumed in most of the stations referred to.

STANDARD GAUGE

The standard deposit gauge, fully described in the first Report, has continued to fulfil its function satisfactorily. Certain difficulties have, however, become apparent during the course of the investigation. For example, the porcelain glaze of the collecting vessels has in one case shown a slight solubility in water, with an accompanying addition to the collected water of the material from the enamel. This has, however, been very slight, and where it has occurred there has been no difficulty in separating the constituent derived from the glaze such as lead, from those normally deposited from the atmosphere. This difficulty has only been noticed in the case of one gauge—that of York, and although the presence of lead in the water was at first attributed to contamination from the lead paint which coated the outside of the gauge vessel, it was subsequently found that the source of the lead was the enamel coating the inner, or catchment, surface of the vessel. Of course, it would be preferable to have an insoluble enamel for this purpose if it were possible to obtain it, but the contamination fortunately being due to a material not normally present in the atmosphere does not affect the results.

Again, during the winter of 1915 several months' observations were lost owing to bursting of the bottles by frost. This is, however, difficult to avoid, as in an exposed position no amount of protection by jacketing or enclosing is sufficient to prevent the water freezing when there is a long continued frost, although for frosts of short duration enclosing the collecting bottles in a wood casing surrounding the stand of the gauge is an effective protection.

The efficiency of this gauge has been criticised on the ground that the rainfall governs the amount of impurity collected, and that the gauge does not measure the total impurity present in the air, since this is not all deposited, some remaining in suspension.

It therefore becomes important to point out that the primary function of the gauge is to collect deposited impurity so as to compare the measurements of the amounts which fall in different localities. The amount collected is not the same as the amount in the air at any one time, but in the long run the greatest amount is likely to be found in the gauge which is exposed to the atmosphere richest in pollution. Naturally rainwater is also collected, but the gauge does not depend on rain for its action, as in dry weather it also collects whatever falls into its catchment area.

The fact that measuring deposited impurity cannot provide complete information as to the degree of atmospheric pollution is very obvious. This point was carefully considered by the Committee at the start, and was dealt with in their first Report under "Methods of Work." It is therefore unnecessary to go over the ground again now, but it may be well to indicate that although a complete statement as to air pollution should deal with suspended as well as deposited matter, the measurement of either alone may be very valuable.

In order to obtain information relative to the very finely divided matter which remains suspended in the air for long periods, the Committee have adopted a standardised form of filter, and this is available for the use of those who wish to obtain more complete information than measurement of deposit alone can give. This filter permits of taking an observation in about 10 minutes and has been exhaustively tested and calibrated.

Relative to the criticism that the rainfall governs the deposit, it will be shown in the present Report that this is not the case. The whole question of the relation of deposit to rainfall has been dealt with rather fully, and it will be seen that while the quantity of soluble matter deposited is evidently affected by the rainfall, this is not true to anything like the same extent for the insoluble parts of the deposit.

ANALYSES

Since issuing the last Report the Committee have had the advantage of a wide experience as regards the chemical procedure. Several difficulties were encountered, but the more important of them have been investigated and where it appeared advisable, from the point of view of scientific accuracy, the "Instructions for Analysis" have been revised.

It has been thought that an account of this part of the work will be of interest, and also useful in the criticisms of the compiled data, and with this in view it has been included in the present Report.

The Committee have received from several of the chemists who are coöperating in the investigation some suggestions and criticisms, and wish to take this opportunity of expressing their appreciation of the assistance derived from them. A Sub-Committee was appointed to inquire into the chemical procedure and to make such recommendations to the Committee as appeared necessary in the light of more than a year's experience.

In its investigations the Sub-Committee had the advantage of making use of the gauges in the County of London, and for this they are indebted to Dr W H Hamer, the Medical Officer of Health to the London County Council, who kindly allowed the Council's chemist, Mr J H Coste, to coöperate.

Errors and Difficulties arising from Algal Growth

Mr A R Tankard, of Hull, drew the attention of the Committee to this matter. The algal growth rendered filtration a tediously slow process, and to some extent was a source of error in the determination of undissolved matter and ammonia. It seemed highly desirable that some steps should be taken to prevent this growth.

Several methods were suggested, the chief of which were the use of

1. Formaldehyde
2. Mercuric chloride
3. Metallic copper
4. Copper sulphate

Mr Tankard kindly undertook to investigate the effect of formaldehyde. It was anticipated by him that the ammonia determination might be interfered with, but owing to the great dilution, it was thought that this would not occur to a serious extent. His experiments proved, however, that the ammonia almost entirely disappeared. In a particular case he showed that water containing 0·006 gramme ammonia per litre contained only one tenth of this amount after three weeks in the presence of formaldehyde (1 part in 20,000). In another case 0·0007 gramme of ammonia per litre was reduced in two weeks to 0·00014 gramme. It was therefore, concluded that the use of formaldehyde was not permissible.

On the other hand, Mr Tankard made some interesting observations on the change in the ammonia contents of the water in the absence of formaldehyde. To quote his own remarks :—

> "In the absence of formaldehyde the ammonia in rain water tends at first to diminish in amount, but after a lapse of time a rapid growth of fungus sets in and the amount begins to increase in some cases. For instance the August rain water here contained 0·0006 gramme per litre when first examined, a week later the amount was 0·0005 and a fortnight after the first determination the amount had fallen to 0·0003 then the quantity of ammonia began to increase and ten days later still had risen to 0·0005 gramme per litre. As the growth of fungus both in rapidity and amount will depend upon a number of factors not readily controllable it cannot be stated that at the end of the monthly period the ammonia found will be a correct indication of the amount washed down from the atmosphere."

Mercuric Chloride.—This was considered by the Sub-Committee but in view of its uncertain behaviour when exposed to heat during the process of analysis it did not seem very promising. Allowance would of course, have to be made in the analysis for the mercuric chloride added.

Metallic Copper.—The growth of bacteria in the water contained in gas holder tanks and similar apparatus has been the subject of investigation in connexion with the operation of gas making plant, and it has been observed that these bacteria can decompose dissolved sulphates with the evolution of H_2S. A point that was observed was that the presence of metallic copper prevented in a large measure the development of bacterial growth. Probably minute traces of a copper salt were formed by the action of the water upon the metal and dissolved in the water, sufficient to prevent within a certain radius of the metal the growth of the bacteria.

It was suggested that if a wire spiral or a strip of pure copper were suspended from the cork of the collecting bottles the growth would be prevented. The dissolved sulphates in the water would probably form copper sulphate with the metal and this would act as an antiseptic. In this case no correction would be necessary for the SO_4, but a small deduction from the total solids and total dissolved matter would have to be made owing to the small quantity of copper added.

After considering this from all points of view it was decided not to adopt it for the following reasons :—

1. Probably both sulphate and carbonate of copper would be formed, thus complicating matters.
2. Additional work would be involved in the separate determination of the amount of copper in solution in the water.

Copper Sulphate.—After considering all aspects of the question the Sub-Committee concluded that copper sulphate seemed to be the best method of dealing with the difficulty. Past investigations indicate that one part of the crystalline salt per million of the water is sufficient to prevent growth, and working on this basis the Sub-Committee have inserted a new paragraph in the "Instructions for Analysis." It was therefore prescribed in the revised "Instructions" that a measured quantity of a standard solution of copper sulphate be added to each of the collecting bottles so as to ensure the presence of this salt to the extent of not less than one part per million. A small correction is necessary on account of the added salt but this involves nothing more than a simple subtraction from the figures for the total dissolved solids and the sulphate.

The use of copper sulphate has proved entirely satisfactory both by general and microscopic observation. In one case a parallel experiment was made on two samples of the same water, one sample of water having added to it copper sulphate to the extent of one part per million. Whereas the untreated sample showed copious algal growth after two weeks exposure the treated sample remained unaltered.

Filtration.—In addition to the avoidance of errors the prevention of algal growth was desirable on the score of easy filtration. However even in the absence of algæ, &c., it is a tedious process to pass the whole volume of collected water through the filter. Mr J F Liverseege in a letter to the Committee suggested decantation after thorough settling. Some experiments have recently been made in London, and it appears that decantation is quite permissible. The amount of suspended matter remaining in the water collected in the London gauges after standing for four days was found to be quite unweighable, in fact, slightly negative results were found on filtering the clear supernatant liquor Decantation is therefore prescribed in the revised "Instructions"

Drying Temperature for Dissolved and Undissolved Matter —The original instructions prescribed 105° C for this In view of the greater convenience of 100° C, it was considered advisable to ascertain if any error would be involved in the change The following observations on London rainfall show the relation between these two temperatures —

Weight of undissolved matter after drying at 100° C	1951	milligrammes
Weight after further drying at 105° C	1935 5	,,
Extra loss due to further drying at 105° C	15 5	= 0 8 per cent of undissolved matter
Weight of dissolved matter after drying at 100° C	1967	milligrammes
After further drying at 105° C	1967	,,
Loss	Nil	

In view of these facts there seemed no need for insistence on 105° C, and therefore 100° C is prescribed in the revised "Instructions"

Chlorine —In view of the greatly diluted character of this constituent it was thought that the usual process of titration might involve errors owing to the solubility of the silver chromate Direct comparison with Volhard's method indicated that no serious error existed It was therefore considered unnecessary to alter the method originally prescribed except to suggest that concentration should precede titration

Ammonia —It was suggested by Mr Tankard that the ammonia might be more accurately determined by Nesslerising direct instead of after distillation, as was originally prescribed

This point has been carefully investigated, and it has been found that under suitable conditions practically the same result is obtained by any one of the three methods referred to The following are some actual observations on the same sample of water —

By distillation and titration	26 5	milligrammes	NH_3
,, ,, Nesslerisation	25 7	,,	,,
,, direct Nesslerisation	26 4	,,	,,

For direct Nesslerisation it is, of course, necessary that the water should not be appreciably coloured

In view of these results full discretion has been given to the analyst in the revised "Instructions"

Ash of Soluble Matter —Section 8 of the revised "Instructions" provides for the addition of ammonium carbonate after ignition This arose out of a suggestion by Mr J F Liverseege The ignition of the residue would tend to decompose any soluble carbonates in the original soluble matter

The advisability or otherwise of the use of ammonium carbonate would therefore depend upon the chemical character of the residue In a particular case this residue obtained from one of the London gauges was found to be made up as follows —

Sodium sulphate	1 227	grammes
Calcium ,,	0·329	,,
Calcium carbonate	0·530	,,
Sodium chloride	0·178	,,

and clearly pointed to the advisability of using ammonium carbonate

Tarry Matter —In the original "Instructions" this was considered to be the loss of weight due to extraction with CS_2

A question arose as to whether this could not be more accurately determined by the direct weighing of the matter extracted by CS_2, but investigation has shown that the extracted matter gains weight on drying, due probably to the oxidation of small quantities of free sulphur and sulphur compounds in the tar The method of determination originally prescribed was therefore retained

The following are the results of observations in London stations —

Station	Tar by difference	Tar by direct weighing
Embankment Gardens	0 153 grammes	0 161 grammes
Finsbury Park	0 220 ,,	0 233 ,,

Other Points —In revising the "Instructions" attention was directed to methods of sampling, quantities of the liquid to be used for various estimations, and to the return of sulphates in terms of SO_3 instead of SO_4

While it is too much to hope that the "Revised Instructions for Analysis" are entirely free from objection, it is believed that they do not leave room for any serious errors

---

"REVISED INSTRUCTIONS FOR ANALYSIS" OF RAIN WATER AND SOLIDS DEPOSITED IN THE STANDARD GAUGE, ISSUED JANUARY, 1916

1 The bottles containing the collected rainfall should be properly labelled with name and number of station and the period of collection, and should be kept standing at the laboratory for several days until completely settled The approximate volume of the liquid should be ascertained at the time of receipt

UNDISSOLVED MATTER

2 The whole of the amount collected should be used for estimating the suspended UNDISSOLVED MATTER

Filtration —3 If the bottle has been allowed to stand for a sufficient time to allow the liquid to become clear, there will be no necessity for the whole volume to be filtered The clear portion can be carefully decanted off by means of a syphon tube inserted so as to reach to within one inch of the bottom of the bottle The bottle should stand at a height above the vessel in which the decanted liquid is to be collected, sufficient for the easy and adjustable discharge of the flow

The filtering medium which has given the best results consists of a layer of pulped filter paper suitably disposed in a Gooch crucible The Gooch crucible should be fitted by means of an adapter to a filtering flask having a side tube for connexion to a vacuum pump

The filter is prepared by weighing a 12 5 cm filter paper or by tareing it against another paper of the same size and beating this with about 200 c c of the decanted liquid By violently shaking this, a very finely divided pulp is produced and part of this is placed in the Gooch crucible and lightly pressed down by means of a glass rod with a flattened end Gentle suction is then applied and the filter is ready for use Should it get clogged up, the pulp, together with any solids collected upon it, may be removed and kept for further treatment and a fresh filter made my placing some clean pulp upon the crucible

Having decanted off the clear liquid to within one inch of the bottom of the bottle the remaining turbid part must be shaken up and transferred to the filter, the bottle being washed out with some of the decanted liquid with the aid of a clean long handled test-tube brush Any paper pulp left over or previously removed is then put on the top of the matter collected in the crucible Should there be more than one bottle of collected rainfall, each should be dealt with in the manner described, the whole of the pulp and the filtered matter being finally placed together in the Gooch crucible for subsequent treatment

Undissolved Matter —4 The Gooch crucible, after its contents have been washed with distilled water is dried to constant weight, the difference between this weight and the weight of the empty crucible plus filter paper representing the TOTAL UNDISSOLVED MATTER A temperature of 100 C is sufficient [illegible] this

Tarry Matter.—5. The crucible is then placed in an extraction apparatus and contents extracted with Carbon bi-Sulphide. The difference found after drying at a 100° C represents the TARRY MATTER.

Ash.—6. The residue from above is ignited for the determination of Ash. Care must be taken that any particles which might possibly drop through the holes in the crucible are not lost. The residue after ignition is the ASH of the UNDISSOLVED MATTER and the loss is the COMBUSTIBLE MATTER insoluble in CS_2. (Allowance, of course, being made for the filter paper.)

DISSOLVED MATTER

In the determination of DISSOLVED MATTER it will be necessary to reserve about eight litres of the decanted liquid. In the event of there being two or more station bottles, a proportional quantity should be taken from each bottle so that when the separate quantities are added together the mixture will represent a true average of the whole of the liquid collected.

Loss on Ignition and Ash.—7. One litre (or smaller quantity if there is a large proportion of dissolved solids present) of the decanted liquid is evaporated to dryness on a water bath and afterwards dried at 100° C to constant weight. The residue is TOTAL DISSOLVED SOLIDS.

The residue is ignited at a dull red heat until all combustible matter has been consumed, then moistened with Ammonium Carbonate and again gently ignited.

Loss is "LOSS ON IGNITION" of matter dissolved in water.

Residue is "ASH" or inorganic matter dissolved in water.

Sulphate.—8. One litre of the decanted liquid should be acidified with Hydrochloric Acid, boiled, Barium Chloride added, filtered, and Barium Sulphate weighed. To be reported as SO_3.

Chloride.—9. 500 c.c. or suitable quantity of the decanted liquid titrated with N/10 Silver Nitrate Solution. If the amount of Chloride present is small the liquid can be concentrated by evaporation before being titrated.

Ammonia.—10. One litre of the decanted liquid just acidified with dilute Sulphuric Acid and concentrated to 100 c.c. This after making decidedly alkaline, to be distilled into N/10 acid and the Ammonia calculated.

(Alternative. If the liquid is not appreciably coloured, 10 c.c. to 25 c.c. may be directly "Nesslerised" with 1 c.c. of Nessler reagent.)

Lime.—11. One litre of the decanted liquid, to which solution of Ammonium Oxalate and a few drops of Ammonia have been added, to be concentrated to 100 c.c., the Calcium Oxalate to be filtered, dried, gently ignited and weighed.

Alkalinity and Acidity.—12. One litre (or smaller quantity) of decanted liquid, if alkaline, to be titrated with N/10 or N/100 Hydrochloric Acid, if acid, with N/10 or N/100 Sodium Hydroxide, using Methyl Orange as indicator, acidity to be calculated as H_2SO_4 and alkalinity as NH_3.

PREVENTION OF GROWTH OF ORGANISMS, ALGÆ, ETC.

Before the bottles are placed in position under the gauges at the beginning of each month, 1 c.c. of an aqueous solution of $CuSO_4 5H_2O$ containing 15 grammes of the crystallised salt per litre should be added to each bottle.

The use of Copper Sulphate as an antiseptic involves a small correction in the determination of TOTAL DISSOLVED SOLIDS and SULPHATES. The following deductions should be made:—

(*a*) From the quantity of TOTAL DISSOLVED SOLIDS (par. 7), as determined from the above instructions, deduct 11 milligrammes for each bottle of rainfall collected.

(*b*) From the "loss on ignition in Dissolved Matter" as determined from the above instructions, deduct 1 milligramme for each bottle of rainfall collected.

(*c*) From the quantity of SO_3 (par. 8) as determined by the above instructions, deduct 5 milligrammes for each bottle of rainfall collected.

NOTES ON THE SELECTION OF CHEMICAL CHARACTERISTICS

It should be pointed out that an examination, even approaching a complete analysis of the deposits of all gauges month by month, would be a task entirely beyond the Committee's resources. Such an analysis would involve the estimation of all elements contained in the deposits, together with their form of combination, and it would not be complete without a botanical and bacteriological study of the organisms present.

In order to devise a simple scheme of investigation, which can be uniformly carried out by any competent analyst, it is necessary to select a few characteristic items which appear likely to throw most light on the nature of the polluting matter, and which can be determined month by month in ordinary routine work for a large number of samples.

The following explanation of the items recorded, together with the reasons for their selection, may be useful for non-chemical readers of these reports.

Total Solids.—This heading comprises all the solid matter suspended either by itself or in combination with water in the atmosphere. A portion of it may be considered as a legitimate constituent of the atmosphere, as air, free from dust of one kind or another, can only be expected at extremely high altitudes. A portion of the total solids is soluble in water and is found by the evaporation of the deposited water or an aliquot portion of it. The remainder, being insoluble in water, appears mostly as a sediment in the collecting bottles after standing for some time. A small portion may remain suspended in the water, particularly after agitation.

Undissolved Matter.—The matter freely suspended in air and insoluble in the deposited water has, obviously, the first claim for examination. It consists largely of dust from the ground and carbonaceous smoke from the incomplete combustion of raw fuel. The composition of the dust varies in different districts according to the geological and surface features of the ground. It is different in town and country and depends upon the kind and state of roads and other open spaces. The portion due to mineral dust in the undissolved solids can be approximately gauged by their percentage of "ash" (this value also includes the "ash" contained in soot or smoke) obtainable upon ignition. However, before igniting the undissolved matter it is extracted with carbon bisulphide. The portion soluble in carbon bisulphide is largely composed of tarry matter, which is derived from the oily constituents of coal smoke.

It must be remembered that coal, on being burnt in a grate, is partly carbonised, yielding volatile products similar to those obtained from a gas retort. Unless the fuel bed is so arranged that these products undergo complete combustion they will issue from the chimney along with the unconsumed sooty carbon. The tarry matter gives, therefore, an indication of the amount and character of the soot contained in the deposits. (The amount of fatty extract from vegetable or animal dust, which would be recorded under this heading, is probably negligible.)

The "loss on ignition" of the undissolved matter represents largely the carbonaceous matter, such as soot, emitted in the form of smoke. It would also represent any organic matter of vegetable or animal origin carried into the air in the form of dust. A further, but relatively small, portion consists of water of constitution from clayey matter, carbon dioxide from limestone, and the like.

Dissolved Matter.—The dissolved matter consists of that portion of the total solids which is readily soluble in water, such as chlorides, sulphates, and other salts. Free acids originally present in the atmosphere, such as sulphur dioxide or sulphuric acid, may react with the basic constituents of the undissolved matter and go into solution either in the course of, or after, deposition.

The only analytical treatment to which the dissolved solids are submitted is the estimation of the total mineral constituents contained in them by ignition. The "loss on ignition," being the difference between their original weight and the weight of "ash" obtained, represents partly combustible organic matter and partly water of constitution or volatile products of decomposition, such as carbon dioxide, ammonium salts, sulphuric or sulphurous acid, nitric acid, &c.

Apart from the above items, the sum of which represents the total solids, the separate estimation of a few constituents, already included in the total or in one of the items, is made, as they appear to throw some light upon the character of the various deposits.

Sulphates.—The sulphates present in the liquid portion are estimated and returned in terms of SO_3—i.e., sulphur trioxide or sulphuric anhydride—which represents the acid portion of all sulphates. The basic portion, such as ammonia, soda, lime, alumina, is not included in this figure. This item can be taken to represent the oxides of sulphur derived from the combustion of coal, oil, or gas containing sulphur of any kind.

Chlorides.—The chlorides are returned in terms of Cl, and do not, therefore, include the basic portion, which would probably consist of alkali or magnesia. It is probable that the greater portion of the chlorides is due to wind borne sea water spray.

Ammonia.—This is returned as free ammonia (NH_3), although it is probably present in most cases in the form of salts, such as sulphate or chloride. It may be derived from the carbonisation of coal in open fires and also from the decomposition or degradation of vegetable or animal nitrogenous matter.

Lime.—The estimation of lime and that of alkalinity or acidity of the deposits is optional, and was included in the analytical scheme with a view to its further extension.

It would be interesting to include tests for a great number of other items in these investigations, for instance, the estimation of the alkalies—iron, alumina—the identification and state of oxidation of the various acid and basic radicles, the separation of organic compounds, and the bacteriological examination of deposits, but, for the reasons stated above, the Committee think it desirable for the present to restrict the experimental work as far as possible, and to obtain the maximum results from the information thus gathered.

RESULTS OBTAINED IN THE YEAR FROM APRIL, 1915, TO MARCH, 1916

CLASSIFICATION ADOPTED

In the first Report of the Committee the numerical results for each element of deposit were classified under certain groups, A, B, C, and D, chosen for the purpose of permitting easy and effective comparison between the stations.

As in the present Report the same classification is adhered to, the preliminary explanatory matter showing the basis of the above classification is here again repeated for convenience of reference.—

Class A includes the stations which have less than 1 unit of deposit per square kilometre.

Class B, the stations which have between 1 and 3 units of deposit per square kilometre.

Class C, the stations which have between 3 and 5 units of deposit per square kilometre.

Class D, the stations which have 5 or more units of deposit per square kilometre.

The unit has been adjusted to suit each separate element, but the proportional division has been kept the same throughout. Thus for "total solids" the unit is 5 tons and the law of classification is—

Class A, less than 5 tons per square kilometre per month.

Class B, from 5 to 15 tons per square kilometre per month.

Class C, from 15 to 25 tons per square kilometre per month.

Class D, from 25 or more tons per square kilometre per month.

It will be understood that the figure 5 belongs to Class B, not Class A, and so on.

The units and limits in the several cases are as follows.—

Insoluble Matter

Unit		Limits			
—	Tons per K² per month	A Less than	B	C	D Over
Tar	0·05	0·05	0·05 to 0·15	0·15 to 0·25	0·25
Carbonaceous other than tar	1	1	1 to 3	3 to 5	5
Ash	2	2	2 to 6	6 to 10	10

Soluble Matter

Loss on ignition	0·75	0·75	0·75 to 2·25	2·25 to 3·75	3·75
Ash	1·5	1·5	1·5 to 4·5	4·5 to 7·5	7·5
Total solids	5	6	5 to 15	15 to 25	25
Sulphates	1	1	1 to 3	3 to 5	5
Chlorine	0·3	0·3	0·3 to 0·9	0·9 to 1·5	1·5
Ammonia	0·05	0·05	0·05 to 0·15	0·15 to 0·25	0·25

Note.—Although sulphates in 1914–15 were returned as SO_4 and in 1915–16 as SO_3, the unit for classification has not been altered, but for the purpose of comparing the two years the sulphates in 1914–15 were re classified as SO_3.

TABLES INCLUDED IN REPORT

Table I shows the monthly deposit for two selected stations, Oldham and Malvern, chosen as showing respectively the greatest and least amount of total solids deposited.

Tables II and III show respectively a comparison of monthly means for all stations for the half years April–September, 1914–15 and 1915–16, and October–March, 1914–15 and 1915–16.

Table IV compares the monthly means for summer and winter months of the year 1915–16.

Tables V and VI give the classification of the elements of pollution under Groups A, B, C, and D for the same periods as Tables II and III and based upon the monthly means as given in Tables II and III.

Tables VII and VIII give the totals of each group, A, B, C, and D, for each element of pollution for all stations taken. These tables are prepared from Tables V and VI and cover the same periods.

Table IX shows the average deposit of each element of pollution for each month for a certain group of 23 stations which provided practically continuous observations over a whole year from October, 1914, to September, 1915. This also shows the amount of each deposit per 100 mm of rainfall.

Table X. is similar to Table IX, but includes the eight London stations only and is for the year from April, 1915, to March, 1916

Owing to the war and the consequent need for economy, the Committee considered it advisable to omit from this Report most of the tables giving the actual monthly deposit for the different stations Two stations are however, given in Table I, selected as having the greatest and least deposit, and it is hoped that the other tables given will prove adequate for the purpose of this Report All monthly returns have been published already *in extenso* in THE LANCET from time to time, and the figures are thus available for any who desire to refer to them.

For the purpose of such reference it may here be stated that the monthly returns and dates of publication were as follows —

Return for		
April, 1915	Published in THE LANCET of	Aug 21st, 1915
May, „	„	Oct 9th, „
June, „	„	Nov 6th „
July, „	„	Jan 29th 1916
Aug „	„	Feb 19th, „
Sept, „	„	Mch 25th „
Oct, „	„	Apl 15th „
Nov and Dec, 1915 and Jan, 1916	„	June 3rd, „
Feb and Mch, 1916	„	July 15th „

It will be observed on referring to Tables II, III and IV that the number of months used to obtain the figure representing "monthly mean" deposit is given for each station It must, however, here be pointed out that when this number falls far short of six for the half year broad inferences cannot be drawn, taking, for example, an extreme case where only one month's record is available for the half year it may be that this month is not fairly representative of the period considered

DISCUSSION OF RESULTS

We may examine the results from several points of view, and it may be well to summarise here the aspects towards which we shall direct our attention. These are—

(1) Comparing the year 1915–16 with 1914–15 is there any indication of an improved state of the atmosphere or the reverse?

(2) What are the stations showing the greatest and least amount of deposit?

(3) How is the amount of impurity deposited affected by the seasons?

(4) Is there any indication of a relation existing between e g rainfall and total deposit or between the different elements of pollution?

To assist in making a more general use of the tables of deposit the following list of equivalents may prove of value

One metric ton per square kilometre is approximately equivalent to—

9 lbs per acre
2 56 English tons per square mile
One gramme per square metre
1 1000 millimetre depth of rainfall

Tables II and III—As these tables are for comparison of the first two years of records they include only such stations as were operating in both 1914–15 and 1915–16

It will be found, therefore, that a greater number of stations are included in Table IV, which refers only to stations at work in 1915–16

Considering first the six summer months, April to September inclusive, and comparing the two years on the basis of total solids deposited, the stations fall into three groups (1) Those in which the total deposit in 1915–16 was greater than in 1914–15, (2) those in which it was less, and (3) the stations which showed no alteration These groups are given below, and for this purpose stations which do not show a greater alteration in total solids than 0 3 metric ton per square kilometre have been placed in Group (3)

Total Solids Deposited in the Summer Months of 1915–16 Compared with 1914–15

Deposit		
Increased in 1915–16	Diminished	Unchanged
Liverpool London — Meteorological Office Embankment Gardens Ravenscourt Park Southwark Park Wandsworth Common Golden Lane Manchester — Cheadle Davyhulme Fallowfield School of Technology Whitefield Oldham Sheffield — Hillsborough Park Meersbrook Park Weston Park Greenock Leith	Birmingham, Central Bolton Malvern Sheffield, Attercliffe York	Kingston upon Hull London, Victoria Park Finsbury Park Newcastle on Tyne Exeter

It is very noticeable here that in the great majority of stations there has been a heavier deposit in the summer of 1915–16 than in 1914–15 This is too uniformly true to be a coincidence, and suggests a common cause

A similar method has been applied to the six winter months and the two years compared on the basis of total solids deposited, with the results given below —

Total Solids Deposited in the Winter Months of 1915–16 Compared with 1914–15

Deposit		
Increased in 1915–16	Diminished	Unchanged
Birmingham, Aston Birmingham, S W London — Meteorological Office Embankment Gardens Finsbury Park. Ravenscourt Park Southwark Park Victoria Park Manchester — Ancoats Philip's Park School of Technology Whitefield Newcastle-on Tyne Coatbridge Glasgow — Bellahouston Park Botanic Gardens Richmond Park Southside Park Greenock Leith	Bolton Exeter Kingston upon Hull Wandsworth Common Manchester — Davyhulme Moss Side Queen's Park Oldham York Glasgow — Alexandra Park. Blythswood square Ruchill Park Tollcross Park Victoria Park	Liverpool London, Golden lane Malvern Manchester, Bowdon

In this case there is again a preponderance of stations in which the deposit has increased, but it is not so marked as for the summer months

If we take the mean monthly deposit in London—i e, the average of all London stations—this was, for the summer of 1914–15, 10 91 metric tons per square kilometre and for the winter 11 41, whereas for the corresponding periods of 1915–16 it was 13 41 and 15 97 respectively, showing a marked increase in both seasons The mean monthly deposit for the whole year in London was in 1914–15 11 16 tons per square kilometre and in 1915–16 14 69, an increase of over 30 per cent

It is to be noted, however, that for the summer comparison in this case there was only one month available in 1914–15 for five out of seven of the London stations

In Tables II and III the summer and winter deposits for each station are compared for the years 1914–15 and 1915–16, and we have seen that the latter year shows a majority of stations with increased deposit In Tables VII and VIII we go a step farther by taking each element of pollution and finding the total of stations giving deposits grouping under Class A, B, C, or D This is derived from Tables V and VI, and like these is based on the mean monthly deposits for summer or winter In the following table we have again reduced Tables VII and VIII to a comparison of the number of A's and B's added together and the C's and D's

Comparison of 1914–15 with 1915–16

—			April to Sept (12 stations)		Oct to March (38 stations)	
			A & B	C & D	A & B	C & D
Total solids	1914–1915		9	3	20	18
	1915–1916		10	2	16	22
Tar	1914–1915	Insoluble	10	2	34	4
	1915–1916		9	3	21	17
Carbonaceous	1914–1915		8	4	25	13
	1915–1916		8	4	30	8
Ash	1914–1915		8	4	28	10
	1915–1916		8	4	27	11
Loss on ignition	1914–1915	Soluble	11	1	25	13
	1915–1916		10	2	14	24
Ash	1914–1915		10	2	13	25
	1915–1916		11	1	10	28
Sulphates	1914–1915		12	0	24	14
	1915–1916		12	0	26	12
Chlorine	1914–1915		12	0	26	12
	1915–1916		11	1	22	16
Ammonia	1914–1915		9	3	26	12
	1915–1916		10	2	25	13

We have therefore now obtained a means of direct comparison between the quantities deposited in the years under consideration

A greater number under A + B in any period indicates a smaller deposit, a greater number under C + D a greater deposit, and we need only examine, say, the C + D column, since the A + B column is simply the complement of the C + D

Considering now the C + D column and comparing the summer of 1914–15 with that of 1915–16, we note that tar, soluble loss on ignition, and chlorine showed a slightly greater deposit in 1915–16 than in 1914–15 Insoluble carbonaceous matter other than tar, insoluble ash and sulphates show no alteration, while total solids, soluble ash, and ammonia were in greater quantity in the year 1914–15

It should, however, be mentioned that the number of stations available for the summer comparison was only 12 hence too much weight must not be put on the above conclusions

Looking at the columns comparing the winter months for the two years, we have a more reliable set of figures, as these are obtained from 38 stations We find here clear evidence of increase in the amount of atmospheric pollution, total solids, tar, insoluble ash, soluble loss on ignition and ash, chlorine, and ammonia have all increased in quantity in 1915–16 The only evidence of reduced deposits in 1915–16 is in the case of insoluble carbonaceous matter other than tar and sulphates

In the following table the stations giving the highest recorded mean monthly deposit as well as the lowest during the whole year April, 1915, to March, 1916, have been selected —

Mean Monthly Deposit, 1915–16, in tons per square kilometre

—	Highest		Lowest	
Total solids	Oldham	29 35	Malvern	1 81
	Manchester—Ancoats Hosp	23 94	Birmingham, S W	6 82
Tar	Glasgow—Bellahouston Park	0 41	Malvern	0·003
	London—Embankment Gardens	0 38	Manchester—Bowdon	0 01
Carbonaceous other than tar	Oldham	5 28	Malvern	0 17
	London—Embankment Gardens	4 64	Manchester—Bowdon	0 46
Insoluble ash	Oldham	16 48	Malvern	0 27
	Manchester—Ancoats Hosp	11 09	Manchester—Bowdon	1 69
Loss on ignition of soluble matter	Glasgow—Alexandra Park	4 89	Malvern	0 49

Chlorine	Manchester—Moss Side	1 54	Birmingham, S W	0 18
	Sheffield—Attercliffe	1 38	Malvern	0 19
Ammonia	Glasgow—Victoria Park	0 24	Malvern	0·02
	Alexandra Park	0·21	Exeter	0·03
	London—Golden Lane	0 21	Manchester—Queen's Park	0 03

It will be seen from this table that there is a great variation in the amount of deposited matter, the maximum being *ten* or more times the minimum It must, however, be borne in mind that Malvern station, which has the minimum deposit in every case except one, is a country station, situated at Malvern Wells, whereas the maximum deposits were invariably in cities Although it does not appear on this table, it is curious to note that the nine Glasgow stations provide examples, in the case of nearly all constituents, of deposits approaching the maximum and also the minimum This will be seen on examining Table IX, which gives mean monthly deposits for the summer and winter months separately

SEASONAL VARIATIONS

In order to examine the seasonal incidence of the various elements of deposit the following methods have been used In Table IV, as mentioned above, the six summer months are compared with the six winter months on the basis of mean monthly deposit This table throws into relief the broad distinction between summer and winter deposits

TABLE I —*Monthly Deposit at the Two Selected Stations, Oldham and Malvern*

—	Station	Rainfall in millimetres	Insoluble matter			Soluble matter		Total solids	Included in soluble matter		
			Tar	Carbonaceous other than tar	Ash	Loss on ignition	Ash		Sulphate as (SO_3)	Chlorine (Cl)	Ammonia (NH_3)

* Malvern sent no returns from August to December, 1915 inclusive
† Oldham discontinued observations after October

To ascertain, however, if there was any regular change from month to month or any obvious relation between the different elements of the deposit, it is clear that one station alone would be unlikely to provide the necessary indication of such relation, should there be any

It was therefore decided to compare the deposit for each month on the basis of an average for all stations for each particular month There was, however, the difficulty that the group of stations observing altered during the year owing to new stations commencing, or existing ones suspending, work, and if not allowed for this would obscure the true seasonal relation, should there be one

It was found that to select only those stations which were in operation from April, 1915, to March, 1916, would leave a very small group, owing to the reduction of stations occurring about the autumn of 1915 owing to the war If, however, the year from October, 1914, to September, 1915, were taken, it provided a group of about 22 stations operating through the whole period, and as this period there fore promised more useful information as to seasonal incidence and relation between the various elements of pollution it was chosen for the purpose

This variation in the number of observing stations is one of the difficulties which the Committee has had to cope with The Committee believes that if the authorities which are coöperating realised this fact they would make a greater effort to maintain their observing stations, at least until the completion of current years on March 31st

It will be convenient now to consider each of the constituents, or elements, of pollution separately, and for this purpose reference must be made to Table IX and the graphs in Fig I

From this table the following list has been prepared showing the months of highest and lowest deposit for each element of pollution, together with the rainfall for comparison It must be kept in mind that Table IX and the graphs in Fig I are prepared from the averages of the monthly deposits of all stations included, the number being given in the table so that except so far as weather variations between the different stations may obscure the result, a fair idea is given of the seasonal incidence of the different elements of pollution and their relation to each other

Table showing the Months of Highest and Lowest Deposit for each Element of Pollution, October, 1914, to September, 1915 Prepared from Average of 23 Stations

—		Highest	Second highest	Lowest	Second lowest
Rainfall		Dec	July	March April June	—
Tar	Insoluble	,,	,,	Sept	Aug
Carbonaceous		July	Dec	,,	April
Ash		June		Aug	Nov
Loss on ignition	Soluble	Dec	Jan	June	March
Ash		,,	Feb	,,	April
Total solids		,,	May	Aug	Sept
SO_3		,,	Jan	June	April
Cl			Feb	,,	Sept
NH_3		Jan	Nov	March	,,

It will be seen from this that loss on ignition and ash of the soluble matter, as well as sulphates, make their highest deposit in December, their second highest in January or February, and their lowest in March, April, or June, thus corresponding closely with the months of greatest and least rain fall It is clear, therefore, that there is some relation between the deposit of soluble matter and rainfall, this will be even more apparent on examining the curves and will be referred to later

Tar and total solids have their greatest deposit in December and least in September and August

The other remaining constituents do not lend themselves to any grouping, but it may be noted that, there is a general tendency for maximum deposits to occur in the winter months and minimum deposits in summer The most notable instance of a maximum deposit in the summer months is that of insoluble ash, and this is more remarkable than the mere examination of the above list would indicate Referring to the graph, Fig I, it will be seen how evident is the increase of this deposit in the fine weather Doubtless the favourable conditions for the production of dust from roads and other sources accounted for this

In last year's Report it was stated that ammonia showed itself as a summer product, this conclusion does not hold good for the period at present under consideration, as it appears that the greatest deposits occurred in January and November, the lowest in March and September Whether the conditions have altered in any way owing to the restrictions on the use of raw coal as a fuel, which are coming more and more into force, it is not possible to say at present, but it is of interest to remember that we are now really comparing the winter of 1914 with the summer of 1915, for the reasons already indicated It may be that when fuel consumption has attained a "steady state" the summer preponderance of ammonia will again appear Or again a comparison of, e g, the summer of 1915 with the winter of 1916 may give an indication of the cause, since if the diminishing use of raw coal is having an effect it should be brought out by such comparison, as in that case it would tend to increase the summer preponderance of ammonia over the *following* winter It is necessary in this connexion to keep in mind the point already referred to in describing Mr Tankard's experiments under "Analyses," which deals with the variation in the amount of ammonia present arising from the growth of organisms in the water collected

TABLE II—*Comparison of Monthly Means for all Stations for the Six Months, April to September, 1914 and 1915*

Un Unreliable

Indicates the letters representing the highest and lowest records for each element in the list of stations
† Indicates the second (if there is one) in Class A or Class D
Ammonia —* Exeter and Malvern equal † Birmingham (Aston) and Finsbury Park equal

In Table IV the summer and winter deposits are compared and if we eliminate from this any stations having less than 4 months observations in either summer or winter we find that a comparison of the amounts of deposit gives the following result

Comparison of Summer and Winter Deposit for Year April 1915 to March, 1916

—		Winter deposit greatest in Stations	Deposits equal	Summer deposit greatest in Stations
Rainfall		24	—	1
Tar	Insoluble	19	1	5
Carbonaceous	Insoluble	14	—	11
Ash	Insoluble	7	—	18
Loss on ignition	Soluble	23	—	2
Ash	Soluble	24	—	1
Total solids		23	—	2
Sulphates		23	1	0
Chlorine		24	-	0
Ammonia		18	2	4
—				

It must be kept in mind that we are now comparing the *number of stations* at which the summer or the winter deposit of any particular element of deposit had the preponderance, this is not a comparison of *quantity* deposited and would only be such if all stations had the same amount of deposit

We note at once that insoluble carbonaceous matter and ash again stand out, the latter as the only case in which the number of stations showing a greater deposit in summer than winter exceeded the number with greatest winter deposit, and the former approaching the same condition *In all* other cases the number of stations with greatest winter deposit greatly exceed the number with greatest summer deposit

It is to be carefully noted that no legitimate inference as to relation of rainfall and deposit can be drawn from these figures Doubtless the summer preponderance of insoluble ash is due to dust

RELATION OF DEPOSITS

Considering first the relation of the deposit of suspended matter to rainfall, it is clear from examination of Table IX and the graphs that there is a close relation between the deposit of soluble matter and rainfall, both rising or falling together We must, however, keep in mind the short period available and the possibility that further observations may not bear out this conclusion At the same time, the parallelism between the curves for rainfall, soluble loss on ignition, soluble ash, and SO_3 is too marked to pass over without notice

On Table IX are also given the deposits per 100 mm of rainfall, and in the last column is given the degree of variation in the figures—i e, the maximum divided by the minimum This column may therefore be read as showing the variation in the figures for any deposit in the form 1 to 4 4 for rain, 1 to 1 95 for tar, and so on

From the point of view of relation between rainfall and deposit we may look at the table in two ways First we may examine the deposits per 100 mm rainfall for the uniformity one would expect if the deposit was in any case a function of the rainfall The column $\frac{\text{maximum}}{\text{minimum}}$ provides an easy way of examining the degree of departure from uniformity We find thus that the greatest variation is in the insoluble ash—4 42, and the next greatest is insoluble carbonaceous—3 62 Chlorine shows a variation of 3 43, but this is misleading, as it is due to one exceptional figure, that for July, and if this were excluded the variation would be reduced to 1 6 Tar, soluble loss on ignition and ash, sulphates, and ammonia all have about the same variation—i e, 2 65 to 2 84 Total solids give a figure of 3 16

It would appear from this, therefore, that the soluble matter is more affected by rainfall than the insoluble the same conclusion as we arrive at from a study of the curves of monthly deposit

We may, however, examine the table in another way If rainfall governed the amount of any element of deposit then we should expect the figures giving the amounts deposited per 100 mm of rainfall to show greater uniformity than the original averages before converting to the 100 mm standard

On looking down the column $\frac{\text{maximum}}{\text{minimum}}$ the following facts stand out —There was during the year a variation in monthly rainfall of 1 to 4 4, thus

providing a sufficient range to bring out the effect of variation It is remarkable to note under these circumstances that in the cases of all elements of deposit, except chlorine and ammonia, there is much more uniformity in the original figures than in those reduced to 100 mm of rain In the case of insoluble carbonaceous matter and ash the original figures vary from 1 to 1 4 and 1 to 1 45 respectively, whereas when converted to deposit per 100 mm rain the range of variation jumps to 1 to 3 62 and 1 to 4 42, showing clearly that these deposits are no direct function of rainfall

The soluble matters show very little change in the range of variation Total solids give a range of 1 to 1 67 in the figures before, and 1 to 3 16 after, conversion to the 100 mm standard The total deposit is evidently therefore no function of the rainfall

Insoluble carbonaceous matter, other than tar, has its greatest deposit in July and the next greatest in December thus corresponding with the two highest rainfalls, but not exactly, since the highest rainfall was in December, whereas the highest deposit of insoluble carbonaceous matter was in July The minimum deposits occurred in September and April also corresponding to rainfall minima, but on the whole the relation is by no means so close as between rainfall and soluble matter, as will be seen from the curves

It may be well here to consider some of the difficulties in the way of establishing relations between the deposits —

(1) Since the soluble parts of deposits are apparently related to the rainfall more closely than the insoluble, it is clear that variation in the rainfall at different stations would disturb the relation between soluble and insoluble deposits at these stations, hence an average of stations is open to this objection On the other hand, no single station could be assumed to be representative of all, in the nature of its deposit

(2) The nature of the deposit and the proportions of the different elements of pollution vary from station to station, so that there will be a tendency for stations with excessive deposits to

govern the nature of any relation brought out by averages

(3) The length of period considered is too short to justify any far reaching conclusions

On the whole, however, it may be expected that any general laws of relationship would apply equally to all stations and should be at least indicated by a consideration of the averages of stations such as we have just dealt with, and the results attained by the method seem to justify this conclusion

With a view to minimising the sources of error referred to under (1) and (2) the group of eight London stations were treated as in Table IX for the year from April, 1915, to March, 1916, with the result shown in Table X In this is also given the deposits per 100 mm of rainfall and the variation in each constituent From this table the following list has been prepared showing the incidence of maximum and minimum deposits during the year —

Months of Highest and Lowest Deposit for Eight London Stations April, 1915, to March, 1916

—		Highest	Second highest	Lowest	Second lowest
Rainfall		Dec	July	June	April
Tar	Insoluble	Nov	Feb	Jan	June March, Dec
Carbonaceous		,	March	Jan	Sept
Ash			Feb	Dec	Jan
Loss on ignition	Soluble	March	Feb	June	August
Ash		,,	Oct , Dec	,,	,,
Total solids		,,	Nov	August	June
SO_4		,,	May	,	,,
Cl		,,	Feb	June	Sept
NH_3		,,	May	Jan	June

FIG I

Average Deposit of each Element of Pollution for each Month for Group of 23 Stations Prepared from Table IX

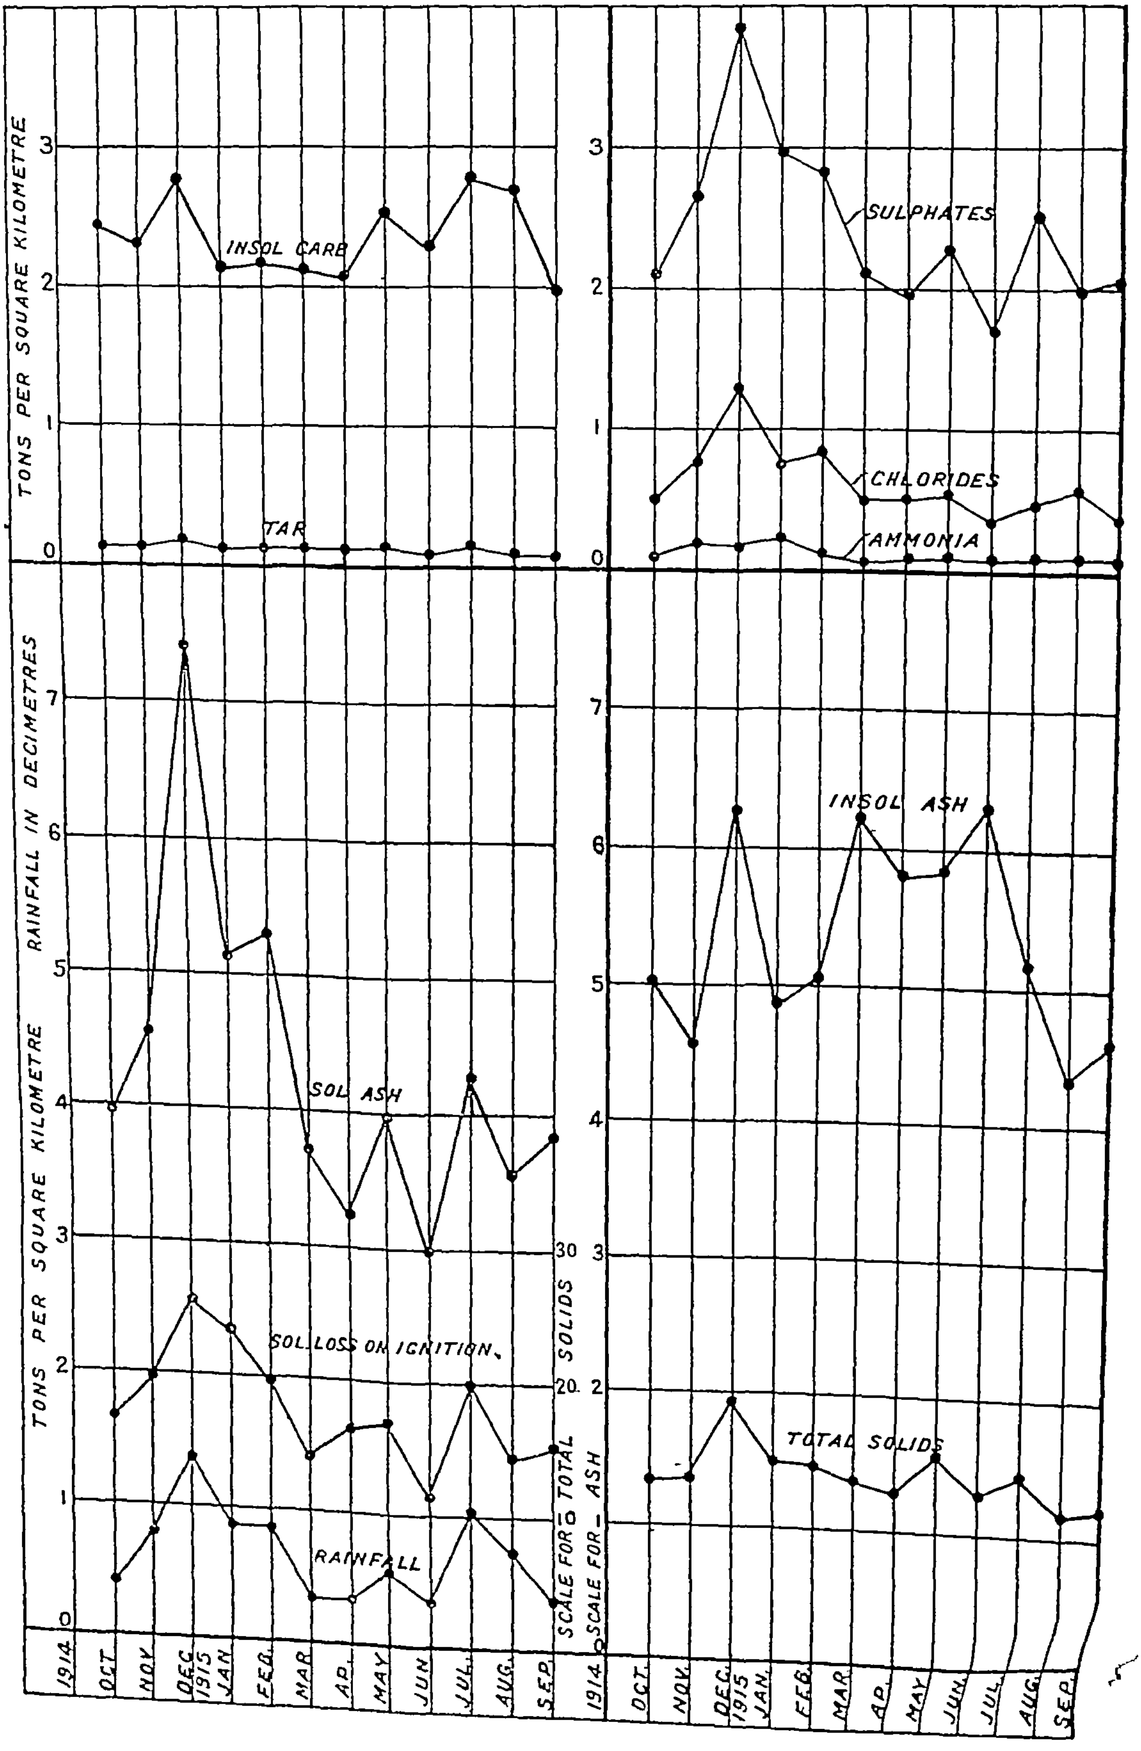

FIG II

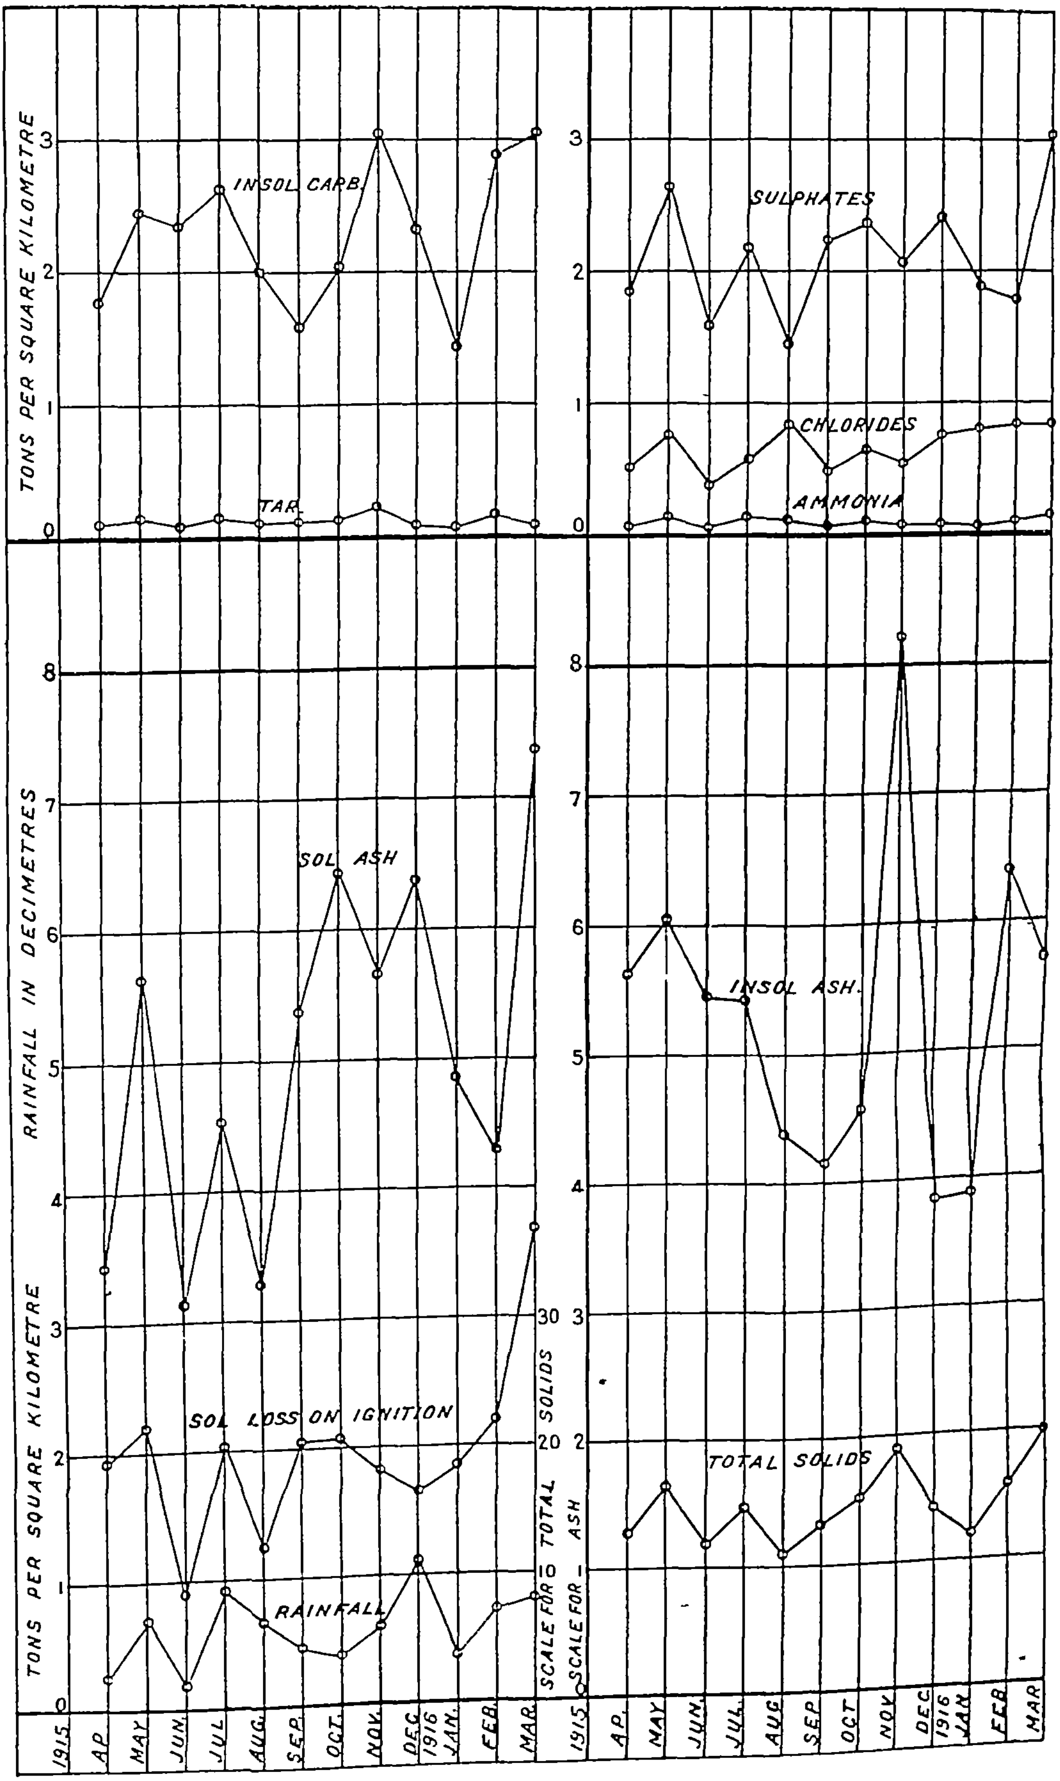
Average Deposit of each Element of Pollution for each Month for Group of London Stations Prepared from Table X



The relations are here more obscure than when the larger number of stations were used While rainfall was greatest in December, no other constituent of the deposit had its maximum in December When these figures are plotted in curves they give very irregular results (Fig II) All that can be said is that the soluble constituents correspond more closely with the rainfall than do the insoluble It would seem on studying the curves, both in this case and Fig I, that for a while some relation holds good, perhaps for four or five months, and then suddenly it breaks down It looks as if there was some fundamental relationship overlaid by erratic occurrences which completely obscure it for a time

In the case of the London stations some such disturbance seems to have taken place about November, 1915, but what its nature was is not easy to say

Looking at the last column in Table X we again notice that insoluble carbonaceous matter and ash show less variation in the deposit before being converted to a uniform 100 mm rainfall, and this in spite of the fact that the monthly rainfall varies from 1 to 6 2 during the year considered All the other elements of deposit exhibit the same characteristic but in a less marked degree, thus bearing out the conclusion drawn from Table IX

Referring to the remarks made previously as to the seasonal incidence of ammonia it is interesting to note for the period April, 1915, to March, 1916, and for the group of London stations considered, that the summer months gave a mean monthly deposit of 0 106, while the mean for the following winter, October to March, was 0 102 ton per k^2, showing a slight preponderance of deposit during the summer The difference is not great enough to base any conclusions upon, but may be noted as indicating, if anything, a slight tendency for ammonia to be present in the water collected in greater quantity in summer than in winter

Speaking generally, the Committee feel that in a report of this nature their special duty is to place the statistics on record rather than attempt to deduce any far reaching conclusions at the present stage of the inquiry For the reasons already given, the tabular results are presented now in a somewhat abbreviated form and it has not been possible to analyse in detail the figures from every station It is hoped, however, that as accurate statistics are made available this will result in stimulating inquiry

OPOLAXYL

Rational Treatment of CONSTIPATION

By the double action of secretions and peristalsis

Opolaxyl is a combination of the secretions of the liver (biliary) pancreas and intestines, with vegetable extracts of a non-drastic nature.

It combines all the secretions to correspond to nature's therapy and promotes a flow of bile and glycogen.

It is a normal regulator of the gastro-intestinal functions, consequently it improves the metabolic exchanges of the entire organism

Opolaxyl does not lose its efficacy by prolonged use, its effect is gentle and constant with the least irritation It is not merely purgative, it stimulates the defective organs and revives the normal equilibrium, it has a lasting effect because it builds the organs, thus correcting diminutional function

Opolaxyl is put up in small size tabular form and should be swallowed without crunching at bedtime or before breakfast

DOSE—For obstinate constipation 2 or 3 tablets, afterwards 1 tablet every 3 or 4 days for a month.

E——— Scotland 9th Oct. 1917

DEAR SIRS—Having derived considerable benefit from the use of Opolaxyl tablets in my own personal case I write as a practising physician to ask if you would make any reduction of price in the event of my sending you an order for a fair quantity say one dozen bottles.

Yours faithfully
C. A—— M D

URASEPTINE

The Most Powerful and Effective Urinary Antiseptic.

URASEPTINE is a granulated product entirely soluble in water, its bases being **Piperazine, Urotropine, Helmitol, Benzoates of Sodium and Lithium** It contains 60 centigrams (10 grs) of active matter to each teaspoonful

DOSE.—2 to 6 teaspoonfuls daily

It purifies the Urine, and this action is due to its three principal properties

1 It is a URINARY ANTISEPTIC
2 A SOLVENT of URIC ACID and of PHOSPHATES
3 A MILD NON-TOXIC DIURETIC

INDICATIONS—**Arthritism, Gout, Gravel, Hepatic and Renal Colic, Rheumatism, Calculus &c, Phosphaturia, Urinary Antisepsis, Pyelitis, Bacteriuria, Cystitis, Prostatitis, Urethritis, Pyuria, Urinary Abscess, Vesical Catarrh, &c**

GALYL

3000 Injections (INTRAVENOUS) of GALYL were given in one of our Service Hospitals

"No case has given the slightest cause for anxiety, and the clinical results are very satisfactory"—*Staff-Surgeon's Report*

IMPROVED INTRAMUSCULAR INJECTION.

The GALYL is in the form of a Sodium Salt in a weak solution of Glucose This is much easier to use and more rapidly absorbed than the oily emulsion. It is in every way identical with the intravenous—efficacy dose, price &c only differing in administration

Thorough and exhaustive tests in various parts of the Kingdom have proved it to be equal in every way with the intravenous moreover patients may resume and continue their occupations without inconvenience after injection of Intramuscular GALYL

Medical Treatment of CANCER.

CUPRASE

Cuprase is a colloidal Copper hydroxide which is obtained chemically by the reduction of Salts of Copper in the presence of Albumosic Acid

The numerous clinical reports from Doctors of repute in various countries give cases of a great variety In all of these pain has been eliminated, and in a good percentage cures are claimed, and in no instance any undesirable effects

Its *easy application* (subcutaneous injections) places it within the reach of all practitioners It *is not toxic*

Disappearance of the Pain
Return of Sleep
Increase of Appetite.
Colour and Strength

WARWICKSHIRE, July 1st, 1917

DEAR SIRS—Will you please send me another box of Cuprase ampoules. The previous lot effected a most remarkable cure in an elderly lady suffering from cervical cancer—the cauliflower-like growth has disappeared with its offensive discharge

This case was given three months life by a Specialist being inoperable

Yours faithfully

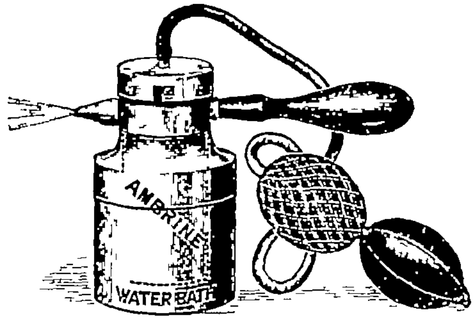
AMBRINE

(The only Authorised Preparation of Dr Barthe de Sandfort Various Imitations compel us to make this statement)

GOUT
NEURALGIA
CHILBLAINS
SCIATICA

The most efficient means and method of ensuring active **Hyperthermal-Therapy** to the practical treatment of **Burns, Varicose Ulcers, Rheumatism, Gout, Arthritis, Neuralgia,** and similar affections



Although the dressing with AMBRINE is occlusive and adhesive, it becomes after a short period non adhesive, and can be removed without pain, hæmorrhage, or injury to the newly forming tissues The healing takes place without leaving scars or contraction

May be applied with a camel s hair brush, but our specially designed spray greatly facilitates the application of Ambrine, especially in the case of wounds or extensive surfaces

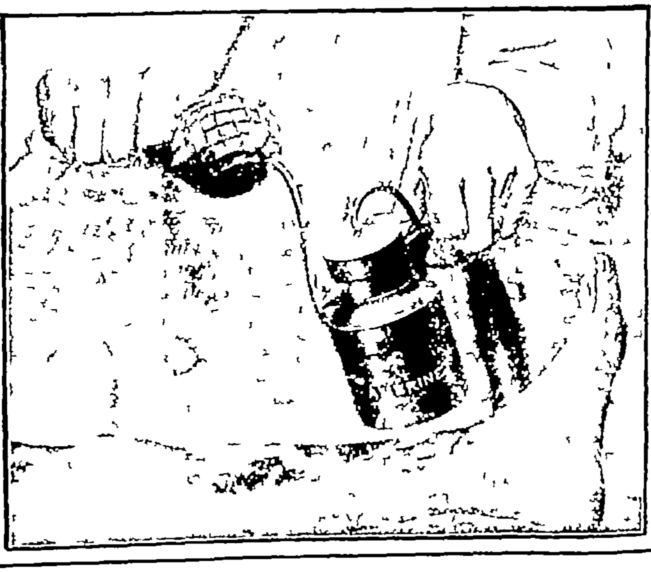
The
BRITISH MEDICAL JOURNAL,
Sept 2nd, 1916 —

Re AMBRINE TREATMENT

' The primary and quite incontestable advantages of the treatment are two it is agreeable to the patient, because entirely painless it is convenient to the surgeon because easily and quickly applied It is possible that the treatment would be useful in dealing with ordinary ulcers and in any case it is certain that the study of its application to the raw surfaces is worth pursuing

K—— co Tipperary
8th Oct 1917

Dr H—— returns thanks to the Anglo-French Drug Co Ltd. for the Ambrine, and found it very satisfactory Herewith enclose P O



THE LANCET,

LONDON SATURDAY OCTOBER 27, 1917

The Position of Practice under the National Insurance Act

A CONFERENCE of Representatives of Local Medical and Panel Committees of Great Britain was held in London on Oct 18th under the auspices of the British Medical Association A year had gone by since the last Conference, and some of the points at issue then were found to have been cleared up, while the focus of interest has shifted in regard to others The perennial difficulty in grasping the working of the "central pool" has remained in spite of the persuasive memorandum issued by the Insurance Commissioners, and the recent Conference decided without hesitation to ask the Commissioners to allow six representatives of the Insurance Acts Committee of the British Medical Association to assure themselves, with the aid of an actuary, that all the money received on account of medical benefit did really find its way into the medical practitioners' pockets In this connexion the existence of "inflation" of the panel list and its effect on medical accounts was fully recognised, being understood more readily in view of the growing familiarity with the process in other departments of life Admittedly there is less inflation in the case of munition centres than in other areas but no action was taken in the direction of pressing for preferential treatment of panel practice in urban areas The Conference was unanimous in wishing to be assured that the total pool was correct, but was not squeamish about its distribution On the contrary, a keen sympathy was expressed with the difficulties of the rural practitioner, which are at their greatest in Scotland (cf p 656) During the year a Rural Practice Subcommittee has been at work considering the special hardships of rural panel practice Two of these hardships have been sadly accentuated during the past 12 months The discharged service man in the country cannot attend personally at his doctor's dispensary, but must be visited, it may be at a great distance The cost of petrol has gone up by leaps and bounds without corresponding increase in the mileage allowance The rural practitioner's time is as valuable as that of his colleagues, and whether or no the mileage allowance covers the out of pocket expenses of his journeys, he has at all events to bear unrequited the expenditure of time involved

The Conference confirmed by an overpowering majority the decision of the Insurance Acts Committee of the British Medical Association in regard to the payment for attendance on the disabled service man by visit instead of on a capitation basis In so doing there was apparently no intention of reversing the doctrine that the capitation fee is the ideal system for medical treatment of an insured population Under whatever other treatment—specialist, training, re educational —the disabled man comes, the capitation fee, if it does nothing else, ensures his surveillance by his own family doctor The arrangement was regarded by the Conference, as by the Insurance Acts Committee which made it, in the light of a temporary expedient in order to elucidate the question whether the disabled soldier is likely to be a more considerable charge on the practitioner's time and skill than his average panel patient Since the decision was made, however, various factors have come in to complicate the situation With some of these we deal on pp 655 6 Treatment by general and V A D hospitals of disabled men as out patients, if it becomes the general policy of the Pensions Ministry, may result in taking this work so completely out of the hands of the practitioner that the fees earned per visit may work out, in fact, less than a capitation fee on the old lines, and this whatever may be the decision of the voluntary staffs of hospitals in regard to their own remuneration The principle of the capitation fee was, indeed, vindicated by the unanimous vote of the Conference to empower the Insurance Acts Committee to press for an increase of the capitation fee to a sum of 10s per insured person, this sum to cover increased liabilities in regard to discharged sailors and soldiers, as well as all services now rendered to tuberculous patients by panel doctors The steadily increasing cost of living and of carrying on practice makes this decision a logical one, in spite of the attitude taken up a year ago not to press the matter on patriotic grounds The increased cost to the Insurance Commissioners of raising the capitation fee was stated to be about half a million pounds, the increase implying a rise of 43 per cent on the panel practitioner s present income, or an addition of £3 per week on a panel of 1000 It is to be hoped that this rise may equitably solve even the difficulties of the rural practitioner in regard to mileage and petrol

The scheme for collective bargaining drawn up by the Insurance Acts Committee of the British Medical Association, as well as its application of the principle during the past twelvemonth, met with the general approval of the Conference, although a small but vocal section expressed its dissatisfaction with the representation of its views by the Committee, not on personal grounds but on the basis of political expediency It was argued that negotiations affecting the panel service should be carried on by direct representatives of the statutory panel committees, and that for this purpose an association of panel committees or a panel medico political union would be more appropriate than a committee of the British Medical Association This movement is an interesting one for a more stringent trades unionism within the medical profession at a time when the Labour Party itself has just taken the step of extending the basis of its representation, and it may not be unfair to compare the constitution of the British Medical Association with that of the reconstituted Labour Party T divergence of opinion on the part of this section of the Conference did not prevent it being perfectly clear that the Insurance Acts Committee of the British Medical Association commands the confidence and support of panel practitioners in general The Committee is not directly under the control of the Association, the present Conference has chosen half of its elected members, and its constitution can still be further amended The Committee has earned approval by consistent endeavour to further the interests of the medical profession at large, and by its efforts to consult the constituency on all important negotiations whenever delay did not endanger the successful carrying through of these negotiations Collective bargaining has become an approved method in panel practice with the Insurance Acts Committee as the bargainer

New Limbs for Old

THE early weeks in the installation of a new head at the Pensions Ministry are justifying its claim to be regarded as a Ministry of Restoration The Statutory Pensions Committee which bequeathed to the Ministry its well organised Local Pensions Committees found prime difficulty in the fact that the great dearth of labour made it possible for almost every discharged man to get work without training, and the men therefore generally did refuse training and went to work without The new Ministry has been concerned to make such generous terms with disabled men undergoing treatment and training that military compulsion could not have been a more potent inducement to them to become effective workers In an admirable article in the October number of "Recalled to Life," the editor, Lord CHARNWOOD, relates his own conversion to this view, and his general survey of the whole subject of disablement will serve to clear the minds of a wide circle of readers The practice of orthopædics has received further impetus from the visit of the American orthopædic surgeons under the leadership of Dr JOEL GOLDTHWAIT, of Boston, and from the institution by the Pensions Ministry of an experimental institute to evolve appliances to help disabled men

The problem of designing artificial limbs which will really assist men in their work was the subject of an important discussion this week at the Medical Society of London Major R C ELMSLIE dealt chiefly with the designing and fitting of artificial limbs on the basis of the work at Roehampton He showed typical examples of this work, which represents an immense mechanical advance on pre war methods Mr E MUIRHEAD LITTLE devoted his remarks chiefly to the adaptation of amputation stumps to the artificial limbs they were designed to carry End pressure and leverage, the two important factors to consider, have quite different values for the upper and lower limbs Artificial limbs for the lower extremity are a comparatively simple matter, their use is limited and definite all that is required is that the appliance shall be strong and reasonably light, that it shall give good stability in standing, and that the gait shall be natural Prosthesis for the upper limb is another matter An artificial arm must be a real working tool Only in the professional classes and for æsthetic reasons will an artificial arm which is passive and of no practical use be worn In order that appliances suitable for all classes of the community may be at hand it will be necessary to have either a number of different models or else a model made in standardised interchangeable parts, by assembling which appropriately a limb can be made which is adapted to the needs of any trade or profession The materials and mechanism should be such as to secure lightness with strength, and if it is possible without losing efficiency the shape should closely resemble that of the natural limb It might be thought that the artificial arm was necessarily a passive appendage, hanging by its attachment to the stump but possessing no active mobility of its own This, however, is not true, at least three movements can be transmitted from the chest and shoulder to the artificial limb, and these can be utilised to produce active flexion of the artificial elbow joint, locking and unlocking of this joint, and opening and closure of the fingers of an artificial hand, or of a grip which replaces it All these requirements and possibilities serve to indicate that the design of an artificial arm is a complex mechanical problem really requiring for its solution the consideration of a mechanical engineer of technical ability and experience The necessities of war surgery have enlisted the assistance of engineers in this direction, and the address on "Mechanical Artificial Arms," delivered by Mr E W HOBBS, A I N A, at the Junior Institution of Engineers, on Oct 15th, embodied the results of two years' experimental work This work was originally undertaken at the instigation of Major ELMSLIE, and the results attained indicate both the complexity of the problem and the success that can be reached if mechanical ingenuity and experience work in coöperation with surgical advice A simple arm can now be supplied which enables its bearer to do the hardest manual work, even to the swinging of a sledge hammer, while in a few minutes this same arm can be rendered sightly and mechanical movements added making it suitable for a professional man Even when the whole limb is lost at the shoulder joint an artificial limb can be fitted capable of voluntary movement at both shoulder and elbow, and of great use to a clerk or for other light occupation

But the problem of artificial arms is not solved with the invention of a suitable appliance and its adjustment to the patient There are complaints abroad, and well founded ones, that men to whom artificial arms are supplied do not use them in their work The reason for this state of affairs is threefold. In some few cases the arm is useless for the man's particular work in others the arm is uncomfortable because it is unsuitable or is a bad fit, but most often the real reason is that the man has never learnt to use his arm, in his trade to its best advantage An artificial arm is a tool, its use must be learnt, just as is the case with any other tool Some men will realise this of their own accord and will set to work to learn the proper use of their limb, but others think that the artificial arm is going to replace the natural one without any effort of adaptation upon their part Such men must be taught to use their limb by an actual training, first in the general use of the artificial arm, and then in its adaptation to their special trade Until an artificial arm has been tested by such methods as these it should not be condemned as useless It would seem that provision for training in the use of artificial arms, either in the hospitals which fit the limbs, or else in local schools or workshops, is required if much of the money which is being spent upon these appliances is not to be thrown away, and if the full work of the armless man is to be secured A Bill is before Parliament for the representation on Local Pensions Committees of the disabled men themselves, and we trust that they will give careful attention to this need

Annotations.

Ne quid nimis "

THE INVESTIGATION OF ATMOSPHERIC POLLUTION

WE publish this week in a special supplement the second report of the Committee for the Investigation of Atmospheric Pollution, the observations recorded being those made during the year 1915–16 The first report appeared in our columns of Feb 26th, 1916, but since that date an important change has been made in the whole scheme of investigation The work is now done under the ægis of the Meteorological Office and the original committee has been constituted an "Advisory Committee on Atmospheric Pollution" to that office The undertaking thus receives official recognition and properly enjoys a status which association with an important Government department confers The committee has received from the Department of Scientific and Industrial Research a *grant in aid of the expert work involved in the investigations*, and thus the pecuniary assistance needed to carry on the practical work should be assured. The *present position is one on which* the pioneers of the movement are heartily to be congratulated it amounts to a well deserved official recognition of work instituted and sustained by what was hitherto a purely voluntary body

In the present report many interesting observations are made, though the reduction in the number of observers, that has taken place owing to the demands of the war has curtailed activities in some directions But, as is appositely pointed out, the connexion between atmospheric pollution and fuel economy is of vital importance just now, for such inquiry brings to light the loss of combustible matter represented by the soot suspended in the air The economic bearing, in other words, has assumed an increasingly serious aspect owing to the call for utilising the energy of coal on a more scientific basis This question is receiving the attention of the Fuel Research Board which, amongst other things, is considering whether the 35 to 40 million tons of raw coal which is used every year for domestic heating in this country, can be wholly or partially replaced by smokeless fuel, solid and gaseous, prepared by the carbonisation of this coal The importance of such an inquiry was urged long ago by the Committee for the Investigation of Atmospheric Pollution, and practical investigations have abundantly shown what an appalling waste of fuel, with consequent pollution of the air and injury to health, our present methods of domestic heating involve In last year's report it was shown that taking the case of the County of London alone the total quantity of matter deposited from the air during the year was approximately 54,200 tons, practically all derived from coal smoke The present report shows, broadly, that far from an improvement having been effected, there has been at certain seasons of the year a heavier deposit in 1915–16 than in 1914–15 A detailed analysis of these cases is set out in the report and they afford an interesting study of the probable causes which underlie the variations in kind and amount of the deposit collected at different seasons To quote examples showing the months of highest and lowest deposit for each element of pollution prepared from an average of 23 stations, we find that the items, loss on ignition and ash of the soluble matter, as well as sulphates, show the highest deposit in December, the second highest in January or February, and the lowest in March, April, or June, thus corresponding closely with the months of greatest and least rainfall This clearly establishes a relationship between the deposit of soluble matter and rainfall Tar and total solids have their greatest deposit in December and least in September and August Generally speaking, maximum deposits occur in the winter months and minimum deposits in summer It is suggested that a preponderance of insoluble ash in the summer may be accounted for not by smoke pollution, but by dust, and the soluble matter is more affected by rainfall than the insoluble There is a mass of valuable material in this report, and it represents careful work in many directions, but there are still some factors missing, and this fact precludes positive assertions being made as to the exact meaning of the results at the present stage of the inquiry For example, the fact that measuring *deposited* impurity cannot provide complete information as to the degree of atmospheric pollution is admitted in the report To some extent such estimation leaves out all consideration of more or less permanently *suspended* matter, and particularly gases, such as sulphur dioxide and ammonia In dry weather these gases would not reach the gauge The attention of the committee is being given to this matter The statistics placed on record by the committee are, however, extremely instructive, and as further work is carried out the results obtained will bring nearer the possibility of making the conclusions definite

THE COMING MINISTRY OF HEALTH

Mr Bonar Law, Chancellor of the Exchequer stated in the House of Commons last week that the creation of a Ministry of Health is under the consideration of the Government, but that at present no general solution of many obvious difficulties had been agreed upon In these circumstances it is clearly wise not to introduce a Bill, but we cannot help feeling that a discussion in the House might tend to remove some of the causes of discord Steps are being taken, the House was informed by Mr Bonar Law, under which agreement will be ensured among those who are actively engaged in the work of national health We do not feel certain that those steps will have that result, the whole medical profession is included "among those who are actively engaged in the work of national health," and considerable divergence of opinion seems to mark their views as yet For example, a large number of those most critical in days gone by of the working of the National Insurance Act are now prepared to regard that Act more favourably, they would give to the National Insurance Commission a predominant part in the future Ministry of Health Dr W A Brend, on the other hand, will have much support for the views which he puts forward in the current number of the *Edinburgh Review* He premises in a short essay on the future of the Public Health Services that experience of the working of the Insurance Act has shown that measure to be seriously defective, and considers that it is an open secret that the National Insurance Act has not fulfilled in many directions what was hoped of it The creation of a Ministry of Public Health is certain to take place, though the difficulties in the way of so important a piece of Parliamentary work are immense at the present moment We trust that there will be no long delay, but we realise that to undertake so critical a piece of work, when due opportunity is wanting for full consideration of the accompanying difficulties, would not be promptitude on the part of any Government, but only mischievous yielding to the view of the muddler that something had better be done, whether for good or for evil As we have pointed out several times in these columns, the position of National Insurance presents considerable difficulties to the designers of a Ministry of Public Health The general view, and one which we have endorsed, is that the Local Government Board should become the over authority for National Insurance, but Dr Brend believes that the office of the Registrar General should be enlarged and should take over the work of the Insurance Commissioners as well as the whole scientific and statistical work in public health at present performed not only by the Local Government Board but by the Home Office and the Board of Education We admit that the Department of the Registrar General could make a good claim if its scope were widened and its staff reinforced by experts, but we remain of opinion that if the National Insurance Commission does not remain a separate bureau, its right place is in a Ministry of Public Health, forming a department of the Local Government Board, and working in that department alongside of the machinery now employed to discharge the medical work of the Home Office and the Board of Education There seems no doubt that we must not expect any concrete proposals from the Government for the creation of a Ministry of Public Health just yet, but this appears to us to be no reason why matters that require immediate reform should remain unattended to until a vague and future date We are glad to learn that it is the intention of the President of the Local Government Board to ask the War Cabinet to allow him to introduce a Bill into the House of Commons immediately, so that it should be passed before Christmas, to deal with the many questions concerned with infant welfare It is evident from his reply to recent deputations that he sees no need whatever to wait for the introduction of a measure to deal with certain existing evils until the Ministry of Health Bill, and he incidentally corrected a mistake made by Mr Kingsley Wood in a letter recently published in the *Times*, who had used the argument for the establishment of a Ministry of Health that it would "save a thousand lives a week" Mr Wood put that prediction into the mouth of Lord Rhondda Lord Rhondda really said that he hoped that a Maternity and Infant Welfare Bill would save a thousand lives a week Dr Brend, in the *Edinburgh Review*, misrepresents Lord Rhondda in exactly the same way

THE HARVEIAN ORATION

Professor R Saundby, in the Harveian Oration which we print in another column, considers Harvey's work in relation to the scientific knowledge and the university education of his time, especially university education in medicine Harvey himself was a pensioner of Gonville and Caius College, Cambridge, where he entered in May, 1593, being then 16 years of age, and where he took his baccalaureate three years later He then left Cambridge to study medicine at the University of Padua, where there was at the time a famous medical school, and while it is admitted that Harvey was the true discoverer of the circulation of the blood, it is fairly clear that our famous British philosopher did not owe so much to his English as to his Italian university, where many eminent philosophers were congregated at the beginning of the seventeenth century, and where he probably acquired the methods of research which led him to his great discovery Professor Saundby's dissertation is largely about other people than Harvey, and forms an interesting chapter of medical history

ACUTE NEPHRITIS WITHOUT ALBUMINURIA

Dr Carl Müller, of Christiania, has recently recorded[1] an interesting case of acute nephritis in which albuminuria was absent during the greater part of the attack

The patient, a factory girl aged 26, was ill with ' kidney disease' for two months in 1914 In 1916 she had a sore throat and kept to her bed for a fortnight, the urine was free from albumin and no diphtheria bacilli were found on examination of a swab from the throat After this she had headache and shortness of breath, with palpitations and a troublesome dry cough, a week later her face and hands swelled and she had pains in the back Dr Müller examined the urine and found no trace of albumin in it The girl was living in miserable surroundings and was taken into hospital Here she was found to have slight œdema of the legs, with a high blood pressure (185 mm Hg), an irregular pulse of 60, slight hydrothorax and ascites, and a small trace of albumin in the urine when Heller's test was applied No formed elements could be found in the centrifugalised urinary deposit A few days later the percentage of urea in the blood was observed to be raised, standing at 0 025 per cent The patient had severe headache, dyspnœa, and vomiting for the first 24 hours, with anorexia On the fourth day she was put on to a salt-free diet of vegetables, bread, milk, tea, and water, and improved considerably The œdema and fluid exudations were absorbed, the urine increased from nearly two to over four pints a day and the blood pressure fell to the normal The trace of albuminuria vanished after a week, at no time could cells or casts be discovered in its centrifugalised sediment A Strauss test applied to the kidneys later showed that the renal excretion of both salt and water was normal

Discussing this case, Dr Müller comments on the extreme rarity of the instances of acute nephritis without albuminuria recorded in the pre war medical literature In trench nephritis, or in war nephritis as he prefers to call it, absence of albuminuria has often been recorded even in instances in which uræmic convulsions have occurred, and he points out that his recorded case in many ways resembles one of war nephritis The attempt has been made to explain some of these cases of œdema without other evidence of renal disease as due really to lack of vitamines in the food, the absence of nervous symptoms makes this explanation improbable Again, it has been suggested that the lack of albuminuria in acute nephritis may be due to patchy involvement of the renal tissue with failure of the inflamed portions to secrete any urine, Dr Müller thinks this explanation untenable, in view of the high blood pressure met with in such patients He comes to the conclusion that acute nephritis without albuminuria is commoner in civil practice than is generally suspected

THE VINDICATION OF A MEDICAL REPUTATION

Dr S D Clippingdale points out that Nov 6th is the anniversary of what he describes as a "tragedy in the annals of English obstetrics," the delivery and death of H.R H. the Princess Charlotte of Wales The untoward event is thus announced in a *London Gazette Extraordinary* issued at the time —

> Her Royal Highness the Princess Charlotte of Wales was delivered of a stillborn male child at nine o'clock last night, and about half past twelve Her Royal Highness was seized with great difficulty of breathing, *restlessness, and exhaustion*, which alarming symptoms *increased till half past two* o'clock this morning, when Her Royal Highness expired

The Princess was in her twenty first year Her grandmother, Queen Charlotte, had been attended in her 13 confinements by a midwife, a Mrs Draper, with the happiest results When, however, the Princess Charlotte was known to be pregnant and an heir to the Throne anxiously desired, it was decided to take every possible precaution Hers was the first Royal accouchement to be attended by male practitioners Three were employed—Dr Mathew Baillie, Dr. John Sims, and Sir Richard Croft Of these, Sir Richard Croft was regarded as a specialist and controlled the case Croft, although he appeared as a maternity specialist, apparently possessed no medical qualification He was at Oxford for a short time, where Foster, in his "Alumni Oxonienses," describes him as "chirurgus privilegiatus," but mentions no degree He was not a Member of the Royal College of Physicians, was not upon the staff of any hospital, nor had he contributed anything to medical literature He was, however, a man of high social position and possibly his social position had something to do with his Court appointment He inherited a baronetcy conferred upon his ancestor by Charles II He married a twin daughter of Dr Denman, the famous obstetrician (to whose practice he succeeded) Dr Baillie, his colleague, married the other twin, so that there was a personal as well as a professional relationship between these gentlemen The Court wished the Princess's confinement to take place at Kensington The Princess, however, preferred Claremont, 15 miles away and, at that time, not easily accessible The labour was protracted and abnormal There was hour glass contraction of the uterus The infant was known to be dead some hours before it was born, yet no steps were taken either to remove it or to terminate labour The Princess was in an enfeebled condition from low diet repeated bleedings, and unrelieved bowels Finally there was post partum hæmorrhage A Mr Jesse Foot demanded a public inquiry, stating, upon the report of the nurse, that when the infant was born, all three doctors were fast asleep This, however, was denied by Dr Sims, who, in a letter which will be found in Playfair's "Midwifery," says "It has been said we had all gone to bed, but this is not a fact Baillie retired about 11 and I lay down in my clothes at 12, but Croft never left her room" A path is still shown at Claremont where Sir Richard Croft had walked up and down in agony not knowing what to do for the best, and Foot's statement that he went to bed is a libel By command of the king a post-mortem examination was made by Sir Everard Home and Sir David Dundas, who reported to the king that there was no evidence of neglect, but that everything had been done which "human science could devise or human skill effect" The event so preyed upon the mind of Sir Richard Croft that three months later he shot himself

COLD AND COLDS

THE bleaker days of early autumn have been accompanied with an abundant crop of colds, and the sequence is such a usual one that many people, perhaps the large majority, regard their catarrh as being directly caused by the reduction of temperature by what they call a chill The belief lacks proof, inasmuch as precaution is generally taken to avoid the reduced temperature by means of artificial heat in houses and offices and the closing of windows in railway carriages But this precaution introduces complicating factors The indoor air becomes more stationary and humid, air pockets are present in which little interchange occurs, there is a sharp dividing line between indoor air and outdoor air, and with these altered telluric conditions there is a tendency to crowd together and an increased nearness of contact in family life In one respect, however, the conditions ahead should be changed in the coming winter Fuel is dear and scarce, and it is both economical and patriotic to be sparing in its use This will mean a reduction in indoor temperature, and less difference between indoors and outdoors It will be worth noting whether the result is an increase or decrease of colds

THE King has nominated Dr J C McVail for a further period of five years a Member of the General Medical Council for Scotland

NEWS has been received of the death, at the age of 60 years, of Sir C Pardey Lukis, honorary surgeon to the King, who has held the position of Director General of the Indian Medical Service for a period of nearly eight years

THE Bradshaw Lecture of the Royal College of Physicians of London will be delivered at the College by Professor Ernest S Reynolds on Thursday, Nov 8th, at 5 o'clock the subject chosen being "The Causes of Disease"

THE Bradshaw Lecture of the Royal College of Surgeons of England will be delivered in the theatre of the College by Sir John Bland Sutton on Thursday, Nov 8th, at 5 P M, the subject of the lecture being 'Misplaced and Missing Organs

THE opening meeting of the Röntgen Society will be held on Tuesday, Nov 6th, at 8 15 P M., at the Royal Society of Arts The presidential address, on 'The Part Played by X Rays in the War,' will be delivered by Captain G W C Kaye M A, D Sc

DEPARTMENTAL COMMITTEE ON THE WELFARE OF THE BLIND

NOTES ON THE REPORT

BY ARNOLD LAWSON, F R C S ENG

AN immense amount of careful, patient, and thorough work is revealed in this report, which is a most complete and thorough exposition of a complicated national problem A cursory glance through its seventy odd pages shows this much, whilst it may be stated that there is not a paragraph which will not repay careful reading and thoughtful consideration. The various issues raised in the discussion of this large subject have each of them received ample attention by the division of the Report into 12 sections or heads followed by a general summary and conclusions

Definition —Statistics and Causation

These sections commence with the Report of the Royal Commission of 1889, followed next (Section II) by a most interesting outline of the scope of the problem This includes statistics and data with regard to the number and occupations of the blind and particulars of the present position as indicated by reports furnished by the various institutions devoted to helping the blind and by the Poor-law returns The section commences by defining blindness for the purpose of the Report In the case of children the definition adopted by the Elementary Education (Blind and Deaf Children) Act, that in this Act the expression "blind" means too blind to be able to read the ordinary school books used by children, is considered satisfactory The definition of blindness in adults has always been a difficult matter, as obviously it is a term that can be applied with fairness to a large number of those who still have a little sight, though insufficient to enable them to lead independent lives The Report decided to adopt the definition of blindness as expressed by the subcommittee of the Ophthalmic Section of the Royal Society of Medicine and adopted by the council of the section (1915), which suggested that "blind means too blind to perform work for which eyesight is essential" It is not likely that any will be disposed to question this definition as being fair, practical, and covering all debatable ground

The Report then goes on to deal with statistics as to blindness and the causes of blindness It points out that with regard to the number of the blind in this country the want of an exact definition as to the meaning of the term has made statistics very unreliable So far as can be gathered, there seems of late years to have been very little change for the better Ophthalmia neonatorum still claims its 10 per cent , but the returns only take us down to 1914, when notification first became compulsory It was suggested by an eminent authority in his evidence on this point that the disease had been practically stamped out in lying in hospitals, but possibly this rosy view will not bear very close investigation It is hard to believe that even the greatest care, and the adoption of every precaution, will suffice to stamp out this disease, which will annually claim a percentage of victims even at lying in hospitals It is to be hoped when returns are available that notification will have proved to have been of some benefit, but the value of notification must necessarily depend upon its reaction with regard to the practical treatment of the disease, and of that we have so far no record

Attention is called to the Report of the Royal Commission on Venereal Diseases, which came to the conclusion that over 50 per cent of all cases of blindness was due to venereal diseases That is undoubtedly a statement which every expert in this country will endorse It is a very serious state of things and will continue to be so in spite of all the new and successful treatment of syphilis until the country has made up its mind to treat the question of syphilis itself in some saner and more practical manner than seems at present likely

Occupational blindness—i e , resulting from injuries received in the course of various trades—should, the Report says, receive more energetic treatment of a preventive nature As a matter of proved fact, no force on earth short of compulsion by Act of Parliament will make the British workman adopt an attitude of common sense in this matter and wear protecting goggles at his work. The Report rightly suggests obligation, but does not mention who is to enforce it

The greater part of the remainder of the Report, until we reach the general conclusions and summary, is devoted to the practical solution of the questions appertaining to the welfare of the blind, and deals therefore with education in its various aspects of elementary, professional and industrial, workshops, and miscellaneous organisations It will be best to follow the Report over these various points by the consideration of the conclusions which follow them These form 12 most admirable pages containing a great deal of original thought, and though some of the conclusions are controversial and unlikely to be adopted as they stand, still they tend to flood the problem of the welfare of the blind with new light, and this undoubtedly will lead to great things in the near future

Central Control

It is noteworthy that the first three paragraphs of these conclusions tread on altogether new ground Placed before the consideration of any one question of education or training, and obviously put in this position in order to make them assume a capital importance, the committee recommend and have drawn up in these paragraphs a scheme of central control Let us see what this means in the words of the Report —

> "We have come clearly to the conclusion that the condition of the blind in the United Kingdom calls for the more active intervention of the State to secure (*a*) central control, organisation, and assistance for the existing agencies of voluntary help, which could be utilised with far greater effect if centrally directed, and (*b*) additional assistance for the blind"

Following this preamble comes the outline of the scheme Shortly it proposes the setting up of a special department known as the "Central Authority in the Ministry of Health," when and if such a Ministry be created, and in the meantime in the Local Government Board, its function to be the general care and supervision of the blind The work would necessarily involve a large financial outlay, partly to meet the expenses involved in starting the recommendations which the committee favour later on (initial capital expenditure) and partly to provide for upkeep (annual expenditure) Much of the money required would probably be, as regards the former item, met by special grants from the votes of the Education Department. The committee are of opinion that the most urgent and expensive essential in this respect is the provision of more workshop accommodation It calculates that about 3000 such shops at a cost of £100–£175 each are needed. involving an outside expenditure of about £500 000 The annual expenditure, it is explained, is extremely difficult to estimate It would be concerned in respect of grants to institutions and organisations for the blind, pensions, and any other purposes which might arise from time to time. It is considered that it would probably be covered by £250,000 per annum Passing on to the constitution of this proposed central authority the committee are of opinion that it should be carried out under the guidance of a strong advisory committee of persons associated with the care of the blind, the chairman of the advisory committee to be the Parliamentary secretary of the office in which the new department is established All matters of policy should be referred to this committee, whilst all executive functions should be exercised by the department working in accordance with the recommendations of the advisory committee.

Such briefly, is the scheme—a really big scheme, and undoubtedly the right one, and far ahead of anything that has hitherto been projected There can be no possible doubt that if the question of the welfare of the blind is to be seriously tackled with a view to permanent and progressive improvement coördination of effort is essential. Coördination of effort can only be obtained by centralisation of effort, and centralisation further means economy of effort. It is the only means of stopping or limiting overlapping of work and extravagance in finance The desirability of a central authority or board is therefore beyond question The practical application of the scheme is obviously controversial, as, for instance, the recommendations as to finance which are pious suggestions based on the theory that the wider you open your mouth the more you will get However that may be there is little doubt that if the principle of a central authority is adopted the money will be forthcoming from somewhere The intrusion of a Government official as the nominal head of such a board may be inevitable though it seems unfortunate It is not to be expected that he would have any special knowledge, and certainly the interference of the State in the management would not conduce, if past history is to be trusted, to the success of the scheme The ideal condition would be State aided but not State-controlled

Certain reservations have been appended to the scheme by some of the members of the committee One of these, dealing with the financial aspect, favours a system of State pensions, for which there is something to be said, but there are many obvious difficulties Even supposing that the greatest supervision is exercised, so that pensions are only granted to those properly qualified there still can be no guarantee that the money is laid out in a suitable way by the recipient, and, further, it is certain that once the pension had been granted it would be exceedingly difficult to take it away, or, in fact, to control it at all, supposing the pensioner should prove himself in the future unworthy of help In another reservation objection is made to the Exchequer being regarded as solely responsible for the necessary funds and a point is made that there are other classes, such as deaf mutes and the paralysed, for whom State aid could be demanded with equal force as for the blind There seems at the present juncture to be no special reason to open a controversy as to ways and means The main point is to establish a working basis and something on the lines suggested by the Report which all the members have signed will be found to be the right guiding principle for action in the future.[1]

Education and Training

The Report favours residential institutions rather than day centres for elementary education of young children, together with the employment of blind teachers whose salaries should be on an equality with those of sighted teachers.

These are two most important points With regard to the first the reservation made by three members that education in residential institutions is not desirable for the majority of *young* blind children has much force Institutional life, as pointed out in this reservation, is a poor substitute for home and family life and it is difficult to understand why a young blind child should be sent to a boarding school at an earlier age than a sighted child. It would, indeed, have been better if the Report had substituted "older for 'young,' or specified some age such as "after ten years of age" The value of blind teachers is a proved fact, and in the future it is hoped that the practice of teaching the blind by the blind will become as universal as it is practicable. The note as to the salary paid to the blind teachers is inspired by obvious fairness

Perhaps the most striking recommendation with regard to elementary education is the initiation of an after care scheme to enable the authorities to keep in touch with each child after leaving the elementary school until he or she can be transferred to the care of either the secondary education authority or to some recognised organisation for the blind. This is excellent

Professional and Industrial Training Workshops and Miscellaneous Organisations

Passing on to the training of adults in all its various phases the Report is extremely practical and this part can be recommended to the careful perusal of all those interested in the subject The following are of special importance.

(*a*) The committee is satisfied that the crux of the problem of the blind in the United Kingdom is the inadequacy of workshop accommodation The evidence is conclusive that the present accommodation should be doubled and even this may not be sufficient

(*b*) In addition inspection and standardisation of production must follow with a system of coöperative buying of raw material and selling of produce

(*c*) Persons who work at home should be visited and assisted in the purchase of materials and the marketing of their goods

(*d*) Particular attention is called to the employment of blind women who except in rare cases are unable to earn anything approaching an adequate wage.

(*e*) There is an urgent need for a central free library for the blind which, acting in coöperation with the home teaching societies and public libraries, would facilitate the circulation and distribution of books available and minimise the danger of unnecessary duplication in production

Each one of the above recommendations is both novel and excellent They all help to show the urgency of a central control authority, without which not one of them is practicable It is devoutly to be hoped that the institution of such a central driving force will not be shelved, and indeed it is not likely that such will be the case, seeing how the war has aroused the general interest of the nation in those who have suffered from it

The Report finishes its work with some recommendations with regard to the administration of the Poor law and pensions and a well-deserved note of confidence and approbation of the steps taken at St Dunstan's Hostel to ensure the welfare of our blinded soldiers and sailors Many of the recommendations of the committee with regard to the training of the blind are at the present time in force at St Dunstan's and are answering well

Place of Ophthalmology in Medical Education

Further, before closing I wish to note a reservation signed by Sir Arthur Downes, who once more desires to draw attention to the memorial to the General Medical Council from the Ophthalmological Society of the United Kingdom in 1891, which points out the desirability of a more general knowledge of ophthalmology by the general medical student it being 'notorious that the general body of the profession does not possess a competent knowledge of diseases of the eye."

That opinion unfortunately, holds as good to-day as in 1891 When will the universities and colleges realise the necessity for a forward move in this respect? This war has shown us many things, and none more clearly than this—viz. the general lack of knowledge of the treatment of eye diseases and injuries Many eminent experts in this branch of surgery are doing their utmost at this moment, and doing it well, but it is only the bare truth that a certain number of blinded men drift from hospital whose sight might at least have been partially saved if their cases had been understood or at any rate treated on proper lines The whole fault lies with the examining boards, the members of whom are admittedly entirely at sea in everything that appertains to ophthalmology, and who, therefore, can hardly be expected to examine students on this subject The students know this, and, having quite enough to do to deal with the subjects of which the examiners are cognisant, they or the greater number of them, simply neglect ophthalmology

NATIONAL INSURANCE ACT

Treatment of the Invalided Sailor or Soldier

MEMORANDUM 234/I C, setting out a scheme for the treatment of sailors and soldiers discharged as no longer physically fit for war service, was briefly summarised in THE LANCET of Sept 8th, p 404 The Memorandum was marked by the Insurance Commissioners who compiled it as being ' For Issue to Doctors," and since its appearance it has received careful attention at the hands of those members and sections of the medical profession likely to be most affected by it Its reception has not been favourable The medical practitioners who serve on the panels and who for the most part, have done so ever since the first National Insurance Act came into force, are not only interested in the matter to a greater extent than their non-panel colleagues, but having been constantly in touch with the practical aspects of the Insurance Acts are, to speak generally in the position of expert critics

The criticisms levelled at the Commissioners scheme are, in the first place, directed against the principle and details of the financial arrangements proposed, the main contention being to quote from a resolution of the Gloucestershire Panel Committee that ' while the machinery of the Insurance Act may conveniently be employed, the expense should be met by a Treasury grant, and should in no way fall upon Insurance funds ' To what extent the proposals of the Commissioners involve drawing upon Insurance funds for the provision of medical benefit for uninsured sailors and soldiers is not quite clear Correspondence which has passed between the Gloucestershire Local Medical and Panel Committee and the Commissioners shows that in the opinion of the latter the former body had misconstrued the intention of the Commissioners, and had not understood the source from which credits in respect of discharged sailors and soldiers are to be added to the central pool The correspondence, however does not state definitely that no money contributed by insured persons for the purpose of providing medical benefit under the Insurance Acts will be diverted towards medical benefit for uninsured sailors and soldiers And whether the discharged sailor or soldier has been insured or not the obtaining for him medical benefit in respect of injury or disease due to military service was not, it may reasonably be said, contemplated when the Act was passed, and was not provided for in it Objection is further taken by many to the institution of a system of payment per attendance in the place of a capitation system to be based upon a reasonable estimate of the services to be rendered

---

[1] On Wednesday last, since this article was written, the Prime Minister has stated that the recommendations of the Departmental Committee will be favourably considered by the War Cabinet.

A second criticism of the payments per attendance proposed is that they are inadequate, and must take into account present and probable future conditions of high prices A further point at issue is the inclusion of non panel practitioners in the scheme in order that they may attend discharged sailors and soldiers only In any case they would benefit by the machinery of an insurance system with which they have refused before to have anything to do, and if any part of the moneys paid to them were derived from Insurance funds, it is contended, they would be receiving money contributed by insured persons and their employers and diverted from the remuneration of practitioners on the panel Memorandum 234/I C , in dealing with the projected inclusion of non panel practitioners, states that it is being brought about "at the request of the medical profession," but the panel committees complain that they have never been consulted at all before the new system was instituted This being the case, the practitioners who have worked, and are working, the Insurance Acts have not had any voice as a body in an expression of opinion ascribed to the "medical profession" It is a point which intimately concerns them, and upon which, and upon the introduction of payment per attendance, they can justly claim that they were entitled to be heard It is to be regretted that such a matter as the medical attendance of those who have suffered so much for their country should give rise to any controversy, but at the same time it is better that an understanding on the subject should be arrived at so far as it is possible at the outset It is highly undesirable that a new system should be initiated without the best possible prospect of smooth working

Insurance Practice in Scottish Rural Areas

A report on medical benefit in Scotland has been prepared, at the request of the Scottish Association of Insurance Committees, by Mr W M Marshall, its secretary and issued as a pamphlet of 48 pages (Motherwell, K Cameron and Co) A section of this report is devoted to the country doctor in Scotland and his difficulties

We may reproduce some passages from the letter of a rural practitioner —

"So long as the medical man is paid per capita the rural practitioner is very seriously handicapped In a town or village practice eight or ten visits at patients' homes can be overtaken in an hour In the country a whole hour may be consumed in visiting a single case The question of roads has to be considered Isolated cottages at considerable distances from the main roads are common, and it is often necessary to leave one's trap or car in the main road, even in the summer time, and accomplish the object on foot In winter, often for weeks at a time, the main roads are impassable through snow drifts, and to reach a patient many miles have to be covered on foot The dangers to be faced, the difficulties to be overcome, and the time lost have all to be considered in estimating the special disadvantages of rural practice Add to that the meagre and often uncertain financial return, and you will get some idea of the lot of the country doctor

It is generally assumed, the report comments that the remuneration of the country doctor for each member on his list is higher than that received by his town colleague in respect that he has fewer services to render and is more rarely called upon for treatment, but it is now certain that the visits by the country doctor are not less in proportion to his list than those made by the town or industrial doctor An examination is appended of the medical records furnished by 15 practitioners in Lanarkshire, three of whom were in practice in rural, two in mixed rural and industrial, and ten in industrial areas In the rural doctors' list 69 per cent are male insured persons and 31 per cent female, as against 79 per cent male and 21 per cent female in the industrial areas In regard to actual services rendered by the country doctor as compared with his industrial colleague, in the case of the first it stands at 4 07 (visits and consultations combined) for each person on his list, as compared with 4 37 for each person on the list of the industrial doctor But the average visits paid work out at 2 85 for every person on the list of the country doctor, and only 1 71 in the case of the industrial doctor The report admits that the evidence gleaned from these few practices is insufficient to justify definite conclusions, but the figures as a whole confirm the view that in justice to the country doctor some readjustment of the terms of service is necessary The figures for Lanarkshire are, indeed, much more favourable to the position of the industrial doctor than the figures for Scotland as a whole If special consideration is not given to these matters there may be increasing difficulty in securing the services of capable and energetic men for the country districts

Obituary.

JOHN GORDON SHARP, M D EDIN

Dr J G Sharp died suddenly from cerebral hæmorrhage on Oct 16th, at his residence, 9, Cavendish road, Leeds, aged 55 years

John Gordon Sharp received his medical education at Edinburgh University, where he obtained the Milner Fothergill Gold Medal in Therapeutics , at Owens College, Manchester, where he was research student in pharmacology, and at Paris and Berlin In 1891 he graduated M B , C M , at the University of Edinburgh, and five years later took the M D degree, for which he was commended About this time—namely some 22 years ago—he bought a practice in the Woodhouse and Meanwood Districts Leeds, and took an active interest in the medical needs of the community in which he had settled He was honorary surgeon to Beckett Home for Waifs and Strays and prominently associated himself in the establishment of the Southern Dispensary in Hunslet-road, which was afterwards amalgamated with the Public Dispensary in North street He was one of its first medical officers and continued to work up to the time the branch was closed owing to the difficulty of getting residents during the war Dr Sharp, who was a prominent pharmacologist, was a member and foreign corresponding secretary for the Section of Therapeutics and Pharmacology of the Royal Society of Medicine, and gained in 1910 the Hunterian Medal for an essay on ergot In October, 1915, he joined the R.A M C as a temporary lieutenant, and did 12 months' service in this country Relinquishing his commission he still continued to do war work at Chapeltown road Barracks and elsewhere until his death He was a frequent contributor to the *Journal of Anatomy and Physiology*, to the *Transactions of the Therapeutical Society* to the *Pharmaceutical Journal*, the *British Medical Journal*, and THE LANCET, his contributions to our own columns including an interesting paper on Intralaryngeal Therapeutics Dr Sharp leaves a widow and two daughters

DR J RAMBOUSEK,

PROFESSOR OF FACTORY HYGIENE, AND CHIEF STATE HEALTH OFFICER, PRAGUE.

WE regret to announce the death, at the age of 43, of Dr Rambousek He was recognised as one of the leading writers and workers on factory hygiene on the Continent and it was noteworthy how ably he seemed to combine the duties of professor inspector, and laboratory worker His industry in collecting material for anything about which he wrote was remarkable. He was best known by his book ' Gewerbliche Vergiftungen " which was translated into English and published by Edward Arnold in 1913 under the title of 'Industrial Poisoning From Fumes Gases and Poisons of Manufacturing Processes " In 1911 he made a short visit to England which he much enjoyed leaving behind him the impression of a delightful personality

Correspondence.

SUCCESS AND FAILURE IN THE TREATMENT OF TUBERCULOSIS

To the Editor of THE LANCET

SIR,—In your leading article of Oct 20th on the above subject a curious mistake occurs in the citation of the Edinburgh Dispensary Scheme as if it represented a special method of *treatment* Coupling it with two other therapeutic procedures, the writer of the article goes on to say that "the hopes raised by these have died down" The reference is apparently to what has been called the Tuberculin Dispensary, with its restricted therapeutic outlook, and not to the Edinburgh Tuberculosis Scheme, for later on the article proceeds —

> The work of the Tuberculosis Dispensaries of our great cities and such an organised system of control as that under the direction of the Chair of Tuberculosis at Edinburgh are on the right lines

The purposes and scope of the Edinburgh Scheme are too familiar to call for detailed re statement now The erection of the Edinburgh Tuberculosis Dispensary in 1887 was a systematised attempt to utilise the discovery of the tubercle bacillus in the interest of public health Its purpose was to create a central institution which would deal with the varying aspects of tuberculosis The lines of its operations, its gradual development as the centre of a communal organisation against tuberculosis, and its several extensions in the sanatorium, the hospital, the tuberculosis school the farm colony, the care committee, &c. are well known They have been detailed in successive papers since the foundation of the dispensary onwards The principles and methods were endorsed by the Local Government Board for Scotland,[1] and subsequently by the Departmental Committee on Tuberculosis [2]

If as you say "a vast social *organisation* to deal with *tuberculosis* has been set in movement," is it wise or just to say that "gloom has fallen on the treatment of tuberculosis'? True for the moment, the large movement—like so many other social activities—is held up through the war Before the crash came, Local Authorities, Insurance Committees &c., throughout the country were beginning to collect and put together the component elements of a satisfactory machinery In some places the machine was almost ready, in others parts were missing, in few places—if in any—was it quite complete When war was declared, things were immediately stopped, and tuberculosis officers who had been appointed to drive the machine were called away by the exigencies of the moment for service with the troops The Local Government Boards have done something to keep men at the tuberculosis posts, but the major necessity has known no law The fact must not be lost sight of, however that the foundations of an efficient anti tuberculosis scheme have been laid A good deal of the superstructure exists, and in numerous centres work is being overtaken The 12 per cent increase in mortality from tuberculosis for 1915-16 does not seem to have occurred uniformly throughout the kingdom and a good deal might be said in explanation of the increase

Of remarkable significance in judging of the value of anti tuberculosis effort is the striking difference between the incidence of tuberculosis among the British troops and its incidence among the French troops Where we calculate in thousands, our gallant Allies have unhappily to reckon in tens of thousands At the present moment the medical service in France is at its wits end to adapt measures equal to the clamant needs with which they have to cope through the ravages of tuberculosis In attempting to determine why this extraordinary difference in the effects of war should present itself in the case of two neighbouring countries with similar civilisation it would be foolish to lose sight of the remarkable difference which existed prior to the war in respect of the coördination of antituberculosis measures An unprejudiced expert observer, Dr Hermann Biggs, puts the matter in a nutshell "In England," he says, 'the tuberculosis problem had been efficiently met before the war, in France, on the other hand, practically nothing had been done"

I am, Sir, yours faithfully,

Edinburgh Oct. 20th 1917 R W PHILIP

To the Editor of THE LANCET

SIR —I have read most carefully the leading article in your issue of Oct 20th, entitled "Success and Failure in the Treatment of Tuberculosis" The subject is of such importance that it is highly desirable that we should be clear as to what we want to do and how we want to do it Your leading article, however seems to me to leave the subject in a very confused condition You say —

> The keen hopes raised by the open air methods introduced from Nordrach, by the Edinburgh Dispensary Scheme, by the Frimley graduated exercises, have died down

And further on in the same paragraph —

> In spite of the vast amount of trouble and administrative machinery we have not kept pace with the disease

Am I not right in concluding that you think all these methods are failures? And yet towards the end of the article you say

> The mechanism of tuberculosis control is good and only requires to be properly applied The work of the tuberculosis dispensaries of our great cities and such an organised system of control as that under the direction of the Chair of Tuberculosis at Edinburgh are on the right lines

How can we reconcile these varying statements? Has not the Edinburgh scheme been under the personal control of the new professor since its inception? How can it be on the right lines and yet be a failure? Surely this and the other methods must be on the wrong lines

You seem to think the failure is due to the patient not applying for treatment until the disease is fully established My experience is that most cases do seek advice early, and are given cough bottles, being assured that they have not got tuberculosis if tubercle bacilli are not found in their sputum You blame the patient for refusing to go to a sanatorium when it has just been stated that the sanatorium method is a failure You state that the practitioner cannot devote enough time to make an early diagnosis What methods do you want the doctor to use? Physical signs such as light percussion or auscultatory signs? Do you think these are reliable methods in the stage it is desirable to make the diagnosis? Are X rays available and always reliable in this earliest stage? If not, what method is the practitioner to rely on? The only reliable method—viz, the subcutaneous inoculation of a *sound* tubercle antigen—is only exceptionally employed.

I quite agree with you when you say that

> No serious progress can be made without close coöperation between these three essential links in the chain of administrative control—the patient, his doctor, and the tuberculosis officer

But I cannot understand the line of thought in the succeeding sentence—

> In certain places where the coöperation has been complete the success of dispensary treatment has been such that undue emphasis has been laid on such minor adjuvants as the administration of certain remedies

If the treatment has been successful where these remedies are used, and unsuccessful or less successful where they have not been used what is one to conclude? Surely that the remedies are what has made all the difference In the last sentence you hope for complete success in the stamping out of the disease on return to normal conditions after the war the greater coöperation with the general practitioner and the more complete training of the tuberculosis officer Training in what methods? In the methods that have produced such a complete failure?

Let me turn now to your attitude towards those who having realised that the at present *practised* methods of prophylaxis are futile wish to try other methods You say —

> The contrast is so vivid between *apparent* administrative failure in regard to tuberculosis and the dramatic success achieved in stamping out enteric fever by means of prophylactic measures that increasing pressure is being brought to

---

[1] Vide Circular on The Administrative Control of Pulmonary Phthisis March 1[illegible] 19[illegible]

[2] Vide Interim Report, 1912, and Final Report 1913

bear on authorities to treat tuberculosis as a contagious disease and the sufferer from tuberculosis as a social pariah to be isolated from his fellows

I would ask if theentericas have been stamped out by isolation of victims of the disease or by preventing their development by prophylactic inoculation ? And why is this prophylactic inoculation done in armies and in individuals who are going to countries where the disease is rife ? Surely because they are nearly certain to get infected, just as we all know, and you point out, the person who does not get infected with tuberculosis in these countries is the exception Why, then, object to trying methods in tuberculosis which have been so very successful in typhoid ? Surely there is a reasonable hope of success

I am, Sir, yours faithfully
W M CROFTON

Laboratory of Special Pathology University College
Dublin Oct 22nd 1917

⁂ Sir Arthur Newsholme's report shows that the war has given tuberculosis a good start while handicapping our measures for dealing with it This looks like failure, and many people, Dr Crofton among them, have taken it as such Sir Robert Philip blames us for giving publicity to this wide sense of discouragement because, as he says the foundations of an efficient anti tuberculosis scheme have been well and truly laid But it was precisely the object of our article to point this out in the face of the evidence to the contrary Our critics do not make any points against us that lead us to alter a single expressed view, though they differ from each other considerably —ED L

WAR DEAFNESSES

To the Editor of THE LANCET

SIR,—With regard to the article on hysterical deafness in soldiers in *THE LANCET of Oct 6th, your leading* article (Oct 13th), and the letter by Major A. F Hurst and Captain E A Peters (Oct 20th) may I be permitted the following remarks The *first case recorded* by the above named authors was so obviously hysterical that it requires no further notice The second case while not so obvious, certainly on the face of it suggests either hysteria or malingering, because complete deafness occurred under circumstances with which we are not accustomed *to associate this phenomenon* It would not, therefore, appear that either of the cases presented much difficulty The observation, however, that in both loud noises failed to waken the patients is interesting

When the authors say "we have found it necessary to discard almost all the criteria *formerly used* in the diagnosis of organic deafness from deafness due to hysteria or malingering" we are entitled to expect something very original, if not epoch making They must be aware that cases of true hysterical deafness are so rare that a careful record of 200 cases would be *expected to* give data which might well come under the latter classification Let us hope that they will not *long* delay the production of their records

With regard to their views as to the importance of vestibular reactions in diagnosis the following objections occur to me 1 Vestibular reactions are present, if perhaps somewhat delayed, in cases of "noise deafness" (sometimes called boilermakers' deafness) 2 In cases of concussion deafness due to artillery vestibular reactions are retained It is inconceivable that the authors desire to deny the occurrence of almost *complete* organic deafness from such causes This brings me to another point They state that in the deafness resulting from cerebro spinal meningitis if there be complete deafness part of it is hysterical The actual fact is that sufficient organic deafness is frequently left to make the sufferer, if a child a deaf mute The question, then of a little more or a little less must be of more academic than practical interest Finally, on what grounds do Major Hurst and Captain *Peters make* the following statement, "But it must be remembered that in partial organic deafness the vestibular reactions are lost in *the severer cases* and exaggerated in the slighter cases" ? My own view is that hysterical deafness may be suspected in cases in which the history indicates a chain *of circumstances* which the experienced observer is not inclined to consider sufficient to account for the great amount *of deafness* For the rest these cases conform to the *type* we are accustomed to meet with in lesions of the sound perceiving apparatus In general the diagnosis can *only* be made with certainty after recovery, which is sudden Unless further proof is forthcoming, I shall be disinclined to attach supreme importance to the presence of vestibular reactions as an aid to diagnosis of hysterical deafness

I am, Sir, yours faithfully
Edinburgh Oct 21st, 1917 P McBRIDE.

DIATHERMY

To the Editor of THE LANCET

SIR —I was much interested in reading in THE LANCET of Oct 20th Dr L W Bathurst's account of the successes he has recently obtained from the use of indirect diathermic fulguration, a method which I originally described in a paper I read before the Electro Therapeutic Section of the Royal Society of Medicine on Feb 18th, 1916 and which appeared in the Proceedings of that Society March, 1916, and also in the *Journal de Radiologie et d'Électrologie* July, 1916

Since I last explained the details of the method to Dr Bathurst I have considerably modified its technique I find that by far the best fulgurating instrument for general use is a Primus Pricker, an instrument sold at any ironmongers in 3*d* packets for cleaning the nipples of the well known Primus petroleum stoves In some cases, such as when treating the hands, or when treating children, or when operating under an anæsthetic, I bandage a 20 × 10 cm electrode on the thigh, *arm*, or abdomen of the patient instead of using the hand electrodes It is not essential to use the somewhat expensive and cumbersome autocondensation couch A very simple and efficient substitute can be cheaply made by taking a three-ply board the size of the consulting room couch or the size of the seat of a large chair placing on this board a piece of zinc about 6 inches smaller in length and breadth and fixing over this zinc a piece of vulcanite one-eighth of an inch thick and overlapping the zinc for 2 inches all round The board is drilled and a terminal attached to the zinc The insulating properties of the board are much increased by soaking it in melted paraffin wax. I have entirely abandoned the use of the ebonite rod, the use of which I *formerly recommended* to Dr Bathurst as I find that a small thin cushion or even a folded blanket, is quite sufficient insulation and far more convenient to use A rubber glove on the *left hand* forms, perhaps the best support, and is very useful in eye *cases for separating the lids*

Indirect diathermic fulguration has a much wider range of usefulness than the cosmetic purposes of which Dr Bathurst writes I have obtained very *satisfactory* and quick results in the fulguration of the nodules of lupus, in the treatment of *rodent* ulcer, chronic *pharyngitis*, *epulis* epithelioma of the cheek, and many other conditions where the destruction of small superficial structures or growths is *required* The accuracy of the application, and the ease and certainty with which its depth of action can be regulated, make it very useful in the treatment of *certain* conditions of the eye and eyelids I have recently been treating by this means, apparently with success, an old standing case of granular conjunctivitis, and also a growth, probably *malignant* of the cornea In the hands of a throat specialist this treatment would, I feel sure, be very *useful for* the destruction of laryngeal growths This method of *fulguration* is in almost daily use at the Radcliffe Infirmary Oxford where its *mode* of application can be seen any morning by appointment

I am, Sir, yours faithfully,
Oxford Oct 21st, 1917 W J TURRELL

THE TREATMENT OF ENURESIS

To the Editor of THE LANCET

SIR,—Enuresis is a *diagnosis* which includes so many causative conditions that I think it would be advisable if Mr A R Thompson, whose *letter on this* subject appeared in your issue of Oct 20th, would describe the class of case for which treatment by gradual dilatation of the bladder is suitable *I am somewhat* surprised that he and his acquaintances are not familiar with this method In my book on "The Diseases of *Children*" 1910 (*p* 566), I refer to it as appropriate for intractable cases after puberty, as in girls constant enuresis may lead *to* the bladder *becoming* unduly *small* Possibly it may be a justifiable measure at an earlier age, in spite of the objections appertaining *thereto* And it must be remembered *that many* and various methods prove curative, probably through the psychical effect. Mere change of surroundings, such as admission to a hospital ward, is sometimes sufficient to break the habit The method is also mentioned by Dr Leonard Guthrie in discussing functional diseases of the nervous system[1] as suitable for inveterate cases of irritable contracted bladder Admitting that the treatment may be advantageous in some cases, I think it should be clearly stated that it is not necessary or advisable for the majority and that it must not be employed indiscriminately It is only appropriate for certain cases which ought to be defined

I am, Sir yours faithfully,

Park-street, W., Oct. 22nd, 1917 EDMUND CAUTLEY

To the Editor of THE LANCET

SIR,—The treatment of enuresis by gradual dilatation of the bladder is not new I carried out the treatment in a very bad case in a girl 14 years of age, acting upon the advice of Mr (now Lieutenant Colonel) E Tenison Collins in 1903 Four ounces was all the girl could take at first, this was gradually increased to 12 ounces, and at the end of a fortnight treatment was stopped. There has been no relapse

I am, Sir, yours faithfully

Penarth Oct 20th, 1917 G P JAMES.

INSANE SAILORS AND SOLDIERS

To the Editor of THE LANCET

SIR,—Dr J F Gemmel in his letter in your issue of Oct 20th objects to 'Service patients" on two grounds. First because they are 'certified', and secondly that being in a public asylum they have the 'taint and stigma' of pauperism. My experience of the social class from which the majority of sailors and soldiers come is that they do not object to certification (a procedure they know little about) so much as to being sent to an asylum. The large military asylums which are suggested would suffer from the same 'stigma' as the county asylum Secondly there are many private patients in public asylums and they do not suffer from the stigma of pauperism. The 'Service patients are private patients

Dr Gemmel has however, put his finger on the weak point of his own plan. One of the greatest pleasures the insane have is to receive visits from their relatives and to deprive them of the possibility of such a privilege would be downright cruelty It is all very well to write of hardships as being unavoidable in war but surely the whole aim of Dr Gemmel's letter is to remove hardships and so far as I can see it merely replaces imaginary ones by a very real one To my mind the Ministry of Pensions and the Board of Control have grappled with a difficult problem in a most satisfactory manner

I am Sir, yours faithfully

City of London Mental Hospital, near
Dartford, Kent, Oct. 20th, 1917 R H. STEEN

THE CONTINUOUS ADMINISTRATION OF ASPIRIN

To the Editor of THE LANCET

SIR,—The following case will perhaps help your correspondent 'J O H."—

A H., a lady aged 30 recently consulted me on account of curious sensations in her head the chief of which was that when she entered a room she always saw a large box over which she had to step before being able to get to the other side The history was that she had suffered from headache for a long time for the relief of which she had taken aspirin freely She was in a very nervous state, very active and anxious to do her duty Thorough examination failed to disclose any actual disease but the ophthalmoscope revealed error of refraction I sent the patient to an ophthalmic surgeon who reported the presence of hypermetropic astigmatism and prescribed glasses. She was ordered to discontinue the use of the drug From that time the patient lost all her headache and other symptoms

I have no doubt that the reckless way in which aspirin is frequently prescribed would account for some obscure nervous conditions. Sisters and nurses in nursing homes are much given to doping patients with aspirin entirely on their own account, a practice which cannot be too strongly deprecated

I am Sir yours faithfully

Harley-street, W., Oct. 17th, 1917 CHARLES W CHAPMAN

The War.

THE CASUALTY LIST

THE following names of medical officers appear among the casualties announced since our last issue —

Killed

Capt R H Spittal, R.A.M C attached Lancashire Fusiliers qualified at Aberdeen University, where he held the appointment of junior demonstrator of anatomy in 1905 and was in practice at South Bank, Yorks, before joining the R A.M C

Lieut D S E Milligan R.A.M C, attached Worcester Regiment, was a student at St Thomas's Hospital London, where he held the appointment of casualty officer, and qualified in the early part of 1915

Lieut. R G Hill M C, R.A.M C, attached Coldstream Guards, received his medical education at St Bartholomew's Hospital, London, where he was at one time senior house physician, and qualified in 1911. He also held an appointment at the Great Northern Central Hospital, and was a surgeon at the British Red Crescent Hospital during the Turco-Italian War of 1912 At the outbreak of the great war he obtained a combatant commission in the Royal Field Artillery and served in France and in Egypt, and later was given a commission in the R.A M C The award of the M C was recorded in THE LANCET of Oct 6th, 1917, p 550

Capt E T Gaunt, R.A.M.C, qualified at Birmingham in 1908, and held appointments at the General Hospital and at the Queen's Hospital Birmingham

Capt G S Elliott Australian A.M C

Capt F C Davies R.A.M C, attached Northumberland Fusiliers, was educated at Cambridge and at Charing Cross Hospital, London, and qualified in 1908 He held appointments at Charing Cross, at West Ham Isolation and at Great Ormond street Hospitals, and was medical adviser to Cambridge Insurance Committee, and county tuberculosis officer at the time of joining the R.A.M C

Capt A. M Fisher, R.A.M C

Died of Wounds

Capt G A. MacFarland, R A M.C, was educated at Belfast, Dublin, and Edinburgh, and qualified at the latter place in 1903 He was at one time assistant medical officer at Hackney Union Infirmary, and later practised in Belfast

Lieut. Col A. W F Sayres R A.M.C, was a student at St Thomas's Hospital London and qualified in 1890 He had held appointments at St Thomas's and at the Bethlem Royal Hospital, London and also at the South Devon and East Cornwall Hospital, Plymouth He was attached to the R A.M C (T.F) prior to the outbreak of war and was in practice at Hartley, Plymouth, where he was tuberculosis officer to the Stonehouse District of the Devonshire County Council

Capt R Sherman, R.A.M C was a student at St Bartholomew's Hospital and qualified in 1912. He held a house appointment at St Bartholomew's, and joined the R.A.M.C in December 1914 Shortly afterwards he went to France and was present at the battles at Loos and on the Somme

Capt (temp Lieut -Col) H Gibson, R.A.M C received his medical education at the London Hospital, and qualified in 1907 and shortly afterwards joined the R.A.M.C

Died

Capt. P Sterling R.A.M C qualified at Durham in 1892, after taking holy orders in 1884 He was for many years a C M.S missionary in Palestine and was an honorary canon of St George's Collegiate Church Jerusalem.

Major H E Dalby, R.A.M C., was a student at Charing Cross Hospital and qualified in 1899 He was in practice at Torquay before going on active service and died at Basra Mesopotamia where he was in command of H M Hospital Ship, *Assaye*

Wounded

Capt. H L Flint R A M C attached East Lancs Regiment
Capt J H Morris-Jones R.A.M C, attached Worcester Regt
Major W E Crowther Australian A.M C
Capt A Nelson New Zealand A.M C
Capt. D A R Haddon R.A.M C, attached Royal Scots
Capt M P Finlayson Australian A.M.C
Capt E B Griffin M.C R A.M C attached Northumberland Fusiliers
Capt. J Tate R A.M C attached Royal Field Artillery
Capt. W E Graham, R.A.M C
Capt W L Halligan, R A.M C attached Royal Warwickshire Regiment.
Capt. P F Walker R.A M C., attached Coldstream Guards
Capt G T Baker R.A M C
Lieut Col P J Hanafin D S O R.A.M C

---

[1] Diseases of Children, Edited by Dr A. E. Garrod, Dr F E Batten, and Dr J H Thursfield, 1913

Capt G Crawshaw, R A.M C , attached East Lancs Regt
Capt H Foxton, R A M C
Capt H A. Higginson, R A M C , attached Lancs Fusiliers
Capt F L Newton, R A M C , attached East Lancs Regt
Capt P R Woodhouse, M C , R A M C , attd Irish Guards

Previously reported Missing, now reported Prisoner in German Hands

Lieut Col G S Williamson, R A.M C

The Honours List

The following awards to medical officers are announced The acts of gallantry for which the awards were made are not yet announced All are members of the R A.M C unless otherwise stated The dates in parentheses, in those cases where bars have been awarded, refer to the number of The Lancet in which a record of the original decoration will be found —

OBITUARY OF THE WAR

ALFRED CECIL EDWARDS M B , Ch B Liverp ,

MILITARY CROSS,

CAPTAIN, ROYAL ARMY MEDICAL CORPS

Captain A. C Edwards, who died from the effects of shell gas in hospital in France on July 25th, at the age of 37 years, was second son of the late Canon Edwards, of Bingley He was educated at the Bradford Grammar School and at Queen Elizabeths School, Kirkby Lonsdale, taking his medical course at Liverpool University and graduating in 1903 After filling resident posts at the Northern Hospital and the South Dispensary in Liverpool, he entered the Colonial Medical Service Receiving a commission in the R A.M C early in 1915, he went to France in May of the same year as regimental medical officer, and remained at the front until his death He was wounded and gassed in December 1915 being awarded the Military Cross His colonel writes of Captain Edwards as a most efficient regimental medical officer

CHARLES WELLER, M R C S Eng , L D S

CAPTAIN ROYAL ARMY MEDICAL CORPS

Captain C Weller, who was killed on active service on August 16th, at the age of about 35 years was second son of Charles Weller of Redhill He was educated in France and took his dental course at Guy's Hospital qualifying L D S in 1905 and M R C S five years later He then entered into partnership in a dental practice in London, which he gave up to join the Expeditionary Force in October 1914, serving at the clearing hospital at Bethune, and later at Choate He was then attached to a field ambulance in connexion with the 1st Cavalry Division and on expiration of his second year, having signed on for the remainder of the war he was at a base hospital until recently relieved by an American unit At the time of his death he was medical officer to a London regiment News was received at the regimental aid post saying that some officers were buried inside a building which had been shelled. On his way to render assistance he received a severe wound in the temple, which he only survived for a few minutes

Captain Weller was an excellent French scholar, and was also well known in the hunting field

Casualties among the Sons of Medical Men

The following additional casualties among the sons of medical men are reported —

Private H S Edwards, Middlesex Regiment, killed in action, eldest son of Dr A S Edwards, of Halling, Kent
Capt R S Adams, Royal Field Artillery, killed in action, only son of Dr R G W Adams, of Wellington, New Zealand
Major H E Dalby R A.M C , died, son of the late Dr W B Dalby, of Torquay
Second Lieut J M De Lacey, West Yorkshire Regiment attached Royal Flying Corps, killed in action, only son of Dr R C De Lacey, of Newcastle on Tyne
Second Lieut R C D Moore, H A C killed in action, elder son of Capt R D Moore, R A M C , of Churchdown, Gloucester
Capt I Heaton, Royal West Kent Regiment died of wounds, son of Capt C J Heaton R A.M C , of Westgate-on Sea
Second Lieut T S Arnold, East Surrey Regiment, attached Lancashire Fusiliers, died of wounds, elder son of Dr F S Arnold, of Berkhamsted Herts
Col H G F Longhurst, Royal Berkshire Regiment, killed in action, youngest son of Dr A. E T Longhurst of Chandlersford, Hampshire
Second Lieut J E Beckingsale, Duke of Cornwall's Light Infantry killed in action only son of Dr D L Beckingsale, of Towyn Merioneth, Wales
Capt (temp Lieut Col) H Gibson, R A M C died of wounds, younger son of Surg Lieut Col G J Gibson A M S (ret), of Totnes, Devon

URBAN VITAL STATISTICS

(Week ended Oct 20th, 1917)

English and Welsh Towns —In the 96 English and Welsh towns with an aggregate civil population estimated at nearly 17 000 000 persons the annual rate of mortality was 12·0 against 11 1 and 11 8 per 1000 in the two preceding weeks In London, with a population exceeding 4 000 000 persons the death rate was 12·9 or 0·9 per 1000 above that recorded in the previous week among the remaining towns the rates ranged from 6 0 in East Ham 6 3 in Acton and in Carlisle and 6 8 in Bury to 18 4 in Fxeter 19 9 in Lincoln and 20·8 in Stockton on Tees The principal epidemic diseases caused 293 deaths which corresponded to an annual rate of 0·9 per 1000 and included 178 from infantile diarrhœa, 54 from diphtheria 33 from measles 25 from whooping cough 8 from scarlet fever and 2 from enteric fever The deaths from diarrhœa which had been 257 272 and 243 in the three preceding weeks, fell to 178 and included 50 in London 12 in Liverpool 11 each in Sheffield and Hull 10 in Manchester and 7 in Birmingham The 1021 cases of scarlet fever and 1314 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were respectively 97 and 43 above the numbers remaining at the end of the previous week Of the deaths from all causes in the 96 towns 118 resulted from violence The causes of 31 deaths were uncertified of which 5 were registered in Birmingham 4 in South Shields and 3 in Darlington

Scotch Towns—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500 000 persons the annual rate of mortality was 12 1, against 10 7 and 11 8 per 1000 in the two preceding weeks. The 244 deaths in Glasgow corresponded to an annual rate of 11 4 per 1000 and included 10 from whooping cough 9 from infantile diarrhœa, 4 from diphtheria, and 2 from measles The 104 deaths in Edinburgh were equal to a rate of 16 3 per 1000 and included 5 from infantile diarrhœa, 2 from whooping-cough and 1 from diphtheria.

Irish Towns—The 137 deaths in Dublin corresponded to an annual rate of 17·9 or 2·1 per 1000 above that recorded in the previous week and included 7 from infantile diarrhœa 2 from measles and 1 each from enteric fever and whooping-cough The 99 deaths in Belfast were equal to a rate of 13 1 per 1000 and included 3 from infantile diarrhœa, 2 from measles, and 1 from whooping-cough

VITAL STATISTICS OF LONDON DURING SEPTEMBER 1917

In the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the ten diseases specified in the table was equal to an annual rate of 4·2 per 1000 of the population, estimated at 4,237 387 persons: in the three preceding months the rates had been 3 4 3 5 and 3 1 per 1000 respectively The lowest rates last month were recorded in Kensington Hampstead the City of London Camberwell Greenwich and Woolwich and the highest rates in Chelsea, Stoke Newington Shoreditch Bethnal Green Southwark and Bermondsey The prevalence of scarlet fever showed a marked increase over that recorded in the preceding month this disease was proportionally most prevalent in Chelsea, Finsbury Shoreditch Bethnal Green Poplar Bermondsey Battersea and Lewisham. The Metropolitan Asylums Hospitals contained 807 scarlet fever patients at the end of last month against 595 644 and 615 at the end of the three preceding months the weekly admissions averaged 138, against 101 and 83 in the two preceding months Diphtheria also was considerably more prevalent than it had been in the preceding month the greatest proportional prevalence of this disease was recorded last month in Paddington St Marylebone, Stoke Newington Shoreditch, Bethnal Green Southwark Bermondsey and Deptford The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals which had been 1042, 1070 and 1003 at the end of the three preceding months had risen to 1111 at the end of last month the weekly admissions averaged 168, against 142 and 122 in the two preceding months. The prevalence of enteric fever was appreciably greater in September than in August the 44 cases notified last month included 7 in Poplar 7 in Wandsworth 4 in Lambeth and 3 in Kensington There were 46 cases under treatment in the Metropolitan Asylums Hospitals at the end of the month against 41 and 45 at the end of the two preceding months the weekly admissions averaged 6 in each of the last two months Erysipelas was proportionally most prevalent in Paddington Holborn Shoreditch, Bethnal Green and Deptford The 14 cases of puerperal fever notified during the month included 3 in Fulham 2 in St Pancras and 2 in Stepney Of the 12 cases of cerebro spinal meningitis 3 belonged to Wandsworth 2 to Hackney and 2 to Camberwell while of the 7 cases of poliomyelitis 2 belonged to Fulham

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ending Sept. 29th the deaths of 3582 London residents were registered, equal to an annual rate of 11 0 per 1000 in the three preceding months the rates were 12 0 10·9 and 10·5 per 1000 The rates last month ranged from 6 6 in Woolwich 7 8 in the City of London 9 1 in Hampstead 9 4 in St Marylebone 9 6 in the City of Westminster 9 7 in Camberwell and 9·9 in Paddington to 12·9 in Stepney 13·2 in Chelsea and in Southwark, 13 5 in Finsbury 14 2 in Shoreditch and 14·9 in Bermondsey The 3582 deaths from all causes included 399 which were referred to the principal infectious diseases of these 23 resulted from measles, 4 from scarlet fever 23 from diphtheria, 38 from whooping cough 9 from enteric fever and 302 from diarrhœa and enteritis among children under 2 years of age No death from any of these diseases was recorded last month in the City of London among the metropolitan boroughs they caused the lowest death rates in Kensington the City of Westminster Hampstead Holborn and Woolwich and the highest rates in Fulham Chelsea, Shoreditch Bermondsey Deptford, and Greenwich The 23 deaths from measles were only half the corrected average of these 23 deaths 7 belonged to Shoreditch, 3 to Stepney and 2 each to Paddington Chelsea, and Poplar The 4 fatal cases of scarlet fever were 9 below the corrected average number and included 2 in Finsbury and 1 each in Bethnal Green and Camberwell The 23 deaths from diphtheria were 18 fewer than the corrected average number and included 4 in Southwark and 2 each in Paddington St. Marylebone, Bethnal Green, and Wandsworth The 38 fatal cases of whooping-cough were 4 below the corrected average and included 4 in Bermondsey 4 in Lambeth and 3 each in Hammersmith Islington, and Southwark. The 9 deaths from enteric fever were 1 in excess of the corrected average and included 2 in Hammersmith 2 in Poplar and 2 in Wandsworth. The 302 fatal cases of diarrhœa and enteritis among children under 2 years of age were 342 less than the corrected average number the greatest proportional mortality from this disease last month was recorded in Fulham Chelsea, Shoreditch, Bermondsey Deptford and Greenwich In conclusion it may be stated that the aggregate mortality in London last month from these principal infectious diseases was 49·7 per cent. below the average

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING SEPTEMBER 1917

(*Specially compiled for* THE LANCET)

Cities and Boroughs.	Estimated civil population 1916	Notified Cases of Infectious Disease												Deaths from Principal Infectious Diseases.									Deaths from all causes	Death rate per 1000 living

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

The Parliamentary Session

PARLIAMENT resumed on Tuesday Oct 16th, after the ntumn recess

A Midwives Bill for Ireland

Mr DUFF the Chief Secretary for Ireland proposes to itroduce a Midwives Bill for Ireland at an early date

War Pensions Committees

A Bill has been presented in the House of Commons by lr HODGE, the Minister of Pensions, for the purpose of roviding for the inclusion on local committees constituted nder the Naval and Military War Pensions Act of repre ntatives of disabled men discharged from the Naval and ilitary Services of His Majesty It has been read a first me

HOUSE OF COMMONS

TUESDAY, OCT 16TH

A Circular Memorandum

Mr PRINGLE asked the Under Secretary for War whether confidential letter was issued by the Director General of iedical Service in June to deputy directors of medical rvice with reference to expediting the discharge of ounded men from hospitals, and, if so, whether he would iblish the letter —Mr MACPHERSON replied My honourable iend is referring, I think, to a circular memorandum issued r the Deputy Director of Medical Services, Scottish Com and, on June 26th last I have ascertained that this rcular was not based upon any special instructions from e War Office but upon general principles As I said in bate on August 17th, I do not think that the interpretation aced upon it by my honourable friend is borne out by the mplete text, a copy of which I will place in the library

Instructions to Medical Boards

Mr BONAR LAW (Chancellor of the Exchequer) informed r PRINGLE that the instructions to medical boards under e new authority had been drawn up and were now being inted They would shortly be laid upon the table of the ouse

Amendment of Insurance Act

Answering Mr HOGGE, who asked when it was proposed introduce a new Insurance Bill Sir E CORNWALL (repre nting the National Insurance Commissioners) said I hope be in a position to give the desired information shortly

Women Workers in V A D Hospitals

Mr BENNETT GOLDNEY asked the Chancellor of the chequer whether he would take an early opportunity of aking it known whether women workers and nurses luntarily or for partial remuneration had undertaken all e arduous and various duties in connexion with Voluntary d Detachment hospitals for our wounded soldiers, whether was aware that many thousands of these women had en carrying on their work for the whole period of the war, atly unnoticed and often forgotten whether he would nember that a number of them had continued to carry their duties at serious sacrifices of both health and ney, and whether in the circumstances he would make h humble representations to His Majesty as would ourably place before him the claims of these women who d already earned the national gratitude to some honour e but inexpensive recognition such as a distinctive ribbon, hat all those who merited it should be able to receive such honour now instead of their being made to wait until ne unknown period after the war when many of them ght have been forced by illness death, or other circum nces to cease their work.—Mr BONAR LAW answered e Government is fully aware of the facts to which my ourable and gallant friend refers in the first three parts of estion. As regards the last part he may rest assured that ry endeavour is being made in conjunction with the irman of the Joint War Committee of the British Red Society and the Order of St John of Jerusalem and the Central Joint Voluntary Aid Detachment Committee ord such recognition as is possible of the services of e ladies and when final details respecting the award of Order of the British Empire have been settled further iculars for the award will be available I am informed neither the War Office nor the other departments con d regard with favour the suggestion that a distinctive on should be instituted

WEDNESDAY, OCT 17TH

Recruiting Medical Boards

r HOGGE asked the Parliamentary Secretary to the istry of National Service whether he could now state h of the recommendations of the Select Committee on al boards the Government had adopted, and whether it was proposed to provide any means whereby men improperly passed into the Army could appeal their cases —Mr BECK replied The organisation of recruiting medical boards is being transferred from the War Office to the Ministry of National Service After a date early in November all men waiting to be called up for military service or holding a certificate of temporary or conditional exemption may claim to be graded by one of the National Service Medical Boards Such re examination will not interfere with a subsequent appeal to an appeal tribunal The machinery for making appeals to appeal tribunals for re-examination will also be ready early in November Medical assessors acting with the appeal tribunals will re-examine all men whose applications for re examination are granted by the appeal tribunals The finding of the appeal tribunal assessors will be final as regards a man's physical condition The appeal tribunals and their assessors are to be administered by the Local Government Board Attested men will have the same rights of appeal as unattested men

THURSDAY, OCT 18TH

A Ministry of Health

Answering Mr DILLON, Mr BONAR LAW (Chancellor of the Exchequer) said The proposal of a Ministry of Health is under careful consideration At present the various difficulties needing to be provided for in the establishment of such a Ministry have not reached any widely agreed solution, and as long as this is so it is not possible to undertake to introduce a Bill for the purpose Steps, however, are being taken which will it is hoped, secure substantial agreement amongst those who are actively engaged in the work of national health

Mr DILLON If substantial agreement cannot be arrived at before the end of the session, will the right honourable gentleman give the House the opportunity of discussing this most important subject ?—Mr BONAR LAW Perhaps the honourable Member will put down a question towards the end of the session and I shall be glad to answer it

Soldiers Suffering from Lung Trouble

Major HUNT asked the Chancellor of the Exchequer whether, in view of the fact that British and Irish troops suffering from lung trouble were not at present allowed to settle in the Dominions, and that there were considerable numbers of these troops suffering from lung trouble caused by service during the war and from gas attacks, and in view of the fact that the Ministry of Pensions had stated their inability to do anything to enable these men to go to and reside in a dry climate as declared to be necessary by medical officers to prevent the development of tuberculosis he could say whether the Government would apply to the Dominion governments for areas of land in their countries to be set apart for the purpose of settling these men in a dry climate and so saving their lives for the Empire —Mr BONAR LAW answered The points suggested in my honourable friend's question are being considered

Surgeon General Sir W Babtie

Mr KING asked the Under Secretary for War whether he could state the present position of those officers censured in the report of the Mesopotamia Commission and what action the Army Council proposed to take —Mr MACPHERSON wrote in reply I am afraid that I cannot add much to the answer which I gave to my honourable friend s question on this subject in August last Surgeon-General Sir W Babtie has submitted his explanation, the Army Council has found it satisfactory and Surgeon General Babtie has been recalled from leave and has resumed his official duties The Council still awaits the explanations of the other officers concerned

Medical Officers of the Territorial Force

Colonel GRETTON asked the Under Secretary for War whether he was aware that a number of medical men joined the Territorial Forces as medical officers *à la suite* with the rank of captain and that an undertaking was given that such officers should be promoted to the rank of major after eight and a half years' service whether he was aware that this term expired in the case of a number of medical officers *a la suite* in June last and that no promotions had taken place and whether it was intended to carry out the under taking which was given at the time these officers joined the service —Mr MACPHERSON (in a written answer) replied The answer to the first part of the question is in the negative Officers appointed to the *a la suite* staffs of general hospitals serve under different conditions to other officers of the Royal Army Medical Corps and promotion is not based on any qualifying time period

Medical Service of the Expeditionary Force

Colonel GRETTON asked the Under Secretary for War whether the Commission recently sent to examine into the medical service of the Expeditionary Force had yet reported if not when the report might be expected and whether it would be laid upon the table of the House —Mr MACPHERSON wrote in reply No report has been received nor can I say when one will be in possession of the Army Council I am afraid that no promise to make the report public can be given in advance

Dental Treatment of Soldiers

In the course of replies to Mr PENNEFATHER, Mr MACPHERSON stated that the total number of commissioned dental officers in the Army was 517

Physical Standards of Recruits

Sir WILLIAM COLLINS asked the Parliamentary Secretary to the Ministry of National Service whether he would lay upon the table of the House the Memorandum which had been prepared containing directions as to the standards of physical fitness of recruits and the classification which was to supersede the present A, B, and C categories with their subdivisions.—Mr BECK replied The Memorandum asked for by my honourable friend is at present under the consideration of the Advisory Medical Board of the Ministry and will be presented to the House at an early date

Exchange of Prisoners of War

In the course of replies to Mr HUME WILLIAMS on the question of the exchange of prisoners of war, Mr J F HOPE (representing the War Prisoners' Department) stated that no prisoners had yet been interned in Holland under the Hague agreement, but 800 prisoners had already been repatriated from Switzerland as a result of it Swiss medical commissioners were now visiting Germany to select British prisoners of war for transfer to Switzerland They had not yet, it was believed, completed their inspection, but once it was accomplished there should be no delay in the despatch of our men to Switzerland

FRIDAY, OCT 19TH

Pay in the Royal Army Medical Corps

Mr JOYNSON-HICKS asked the Under Secretary for War what was the pay at home and abroad of a captain in the Territorial Royal Army Medical Corps and a lieutenant in the new Royal Army Medical Corps —Mr MACPHERSON replied The pay and allowances of a captain in the Territorial Force, Royal Army Medical Corps, vary from 19*s* to 22*s* 2*d* a day The pay of a temporary lieutenant engaged on a contract basis is 24*s* a day inclusive The captain is entitled to a larger gratuity on cessation and to other advantages, but the question of the comparative emoluments is under the consideration of the Council

Mr JOYNSON HICKS Is the honourable gentleman aware that there is very grave dissatisfaction in the Territorial Medical Force in regard to this apparent discrepancy?—Mr MACPHERSON did not reply

MONDAY, OCT 22ND

National Insurance Payments

Mr SNOWDEN asked the representative of the National Insurance Commissioners whether he was aware that the panel doctors in many parts of the country, especially in rural districts, had only received from 25 to 50 per cent of the sums due to them for their services for the year 1916, and whether steps would be taken at once to pay up these outstanding arrears and thereby remove a sense of grievance under which these men were suffering —Sir E CORNWALL replied In the great majority of cases the final payments of the doctors have been completed for the year 1916 In those areas where some balance of the year's remuneration is outstanding, the amount can only be small, as the sums which have been advanced monthly or quarterly during the year will have approximated to the total sums which will be found to be due on the final settlement I think, therefore, the honourable Member must have been misinformed but if he will furnish me with particulars of any cases which he has in mind I will cause inquiries to be made

Imports of Opium

Sir WILLIAM COLLINS asked the Parliamentary Secretary to the Board of Trade whether Indian opium was now largely used in this country in place of opium of Turkish or Persian origin for the manufacture of morphia and officinal preparations, and how much opium was used for these purposes in the year 1916 and what were the sources from which it was derived —Mr WARDLE wrote in reply I am informed that for the last 18 months Indian opium has been practically the only description available for morphia manufacture, Persian supplies being relatively insignificant The following statement shows the total net quantity of opium retained for use and manufacture in the United Kingdom in 1913 and 1916, and the countries from which it was originally consigned —

Net Imports of Opium Retained

Consigned originally from —	*1913* lb	*1916* lb
India	4 824	437,237
Persia	35,020	82,362
Turkey	270,123	25 843
Other countries	45,393	15,237

* Exports in excess of imports

TUESDAY, OCT 23RD

Dental Service in the Army

Colonel YATE asked the Under Secretary for War whether the dental service of the Army was in charge of a special director general or of any recognised head of the dental service, what number of dentists were attached to each division, and, if less than one to each division, would he have arrangements made to complete to that strength —Mr MACPHERSON replied The Director General, Army Medical Service, is the recognised chief of the dental officers employed with the Army There are no dentists in the war establishment of divisions, such officers being allotted to duties in the field at the discretion of the general officer commanding in chief and it is not proposed to interfere with the discretion of these officers in this matter

Medical Appliances in Mesopotamia

Mr E WASON (on behalf of Sir J JARDINE) asked the Under Secretary for War whether as regards the troops at all the stations on the Shatt-el Arab, the Tigris, and Euphrates he was in a position to assure the House that sufficient provision had been made for medical and surgical treatment including medicines and appliances, and for the supply of fresh vegetables, and whether and what, provision had been made of fruits —Mr MACPHERSON said in reply The General Officer Commanding in Chief is responsible that sufficient provision is made for the medical and surgical treatment, including medicines and appliances for the troops at all stations in any particular theatre of war, and I have no reason to suppose that provision in Mesopotamia is not merely sufficient but ample in every respect All demands for medical stores are promptly met and in addition to the medical store depots in Mesopotamia a special depôt has been established at Bombay to facilitate supply The supply of fresh vegetables is good and amounts to 67 per cent of the total vegetable ration Fruit and dates are also available locally and issued to the troops

Appointments.

Successful applicants for vacancies Secretaries of Public Institutions and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o clock on the Thursday morning of each week such information for gratuitous publication*

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures original articles, and reports should be written on one side of the paper only, *and when accompanied by blocks it is requested that the name of the author and if possible of the article, should be written on the blocks to facilitate identification*

Letters whether intended for insertion or for private information must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

The Twentieth-Century Fire

> "*In the winter, warmth stands for all virtue*"
> —THOREAU

BUT it must be the right kind of warmth—that of the modern gas fire, for instance, the fundamental principle of which is **radiation**

Such a fire gives out between 70 and 80% of its heat in the form of rays which heat the solid objects in a room without raising the temperature of the intervening air and causing any unpleasant drying effect, and is, moreover, so designed that, provided it is properly fixed, every trace of products of combustion is carried away through the flue

Hence it may be said with truth that the twentieth century gas fire possesses all the merits of hygienic construction in addition to those of convenience and economy

Medical Men who would care to have further information of these points are invited to apply, free of charge or obligation, to the Secretary, The British Commercial Gas Association 47, Victoria Street, S W 1

At all times Pure Wool

You can safely recommend Wolsey as the Pure Wool Underwear Before the War Wolsey was pure wool—in spite of the increased price to-day Wolsey is still pure wool—and in future times of peace Wolsey will be pure wool Every garment made from new and carefully selected wool & manufactured by British labour under hygienic conditions The underwear for great comfort and long service

Wolsey

Pure Wool Underwear

For men women and children Guaranteed unshrinkable or replaced free of cost The Wolsey Trade Mark is on every garment

The manufacturers of Wolsey will be glad to show any Doctor over their factories if he should be in Leicester A postcard will ensure arrangements being made to receive him.

THE WOLSEY UNDERWEAR CO
LEICESTER.

Vitamogen

Vitamines

"THERE are so many proprietary foods on the market nowadays that it might seem at first sight superfluous to add to the number Vitamogen, however contains something fresh and original inasmuch as it is the first attempt to make practical use of the epoch making discoveries of Funk and others, which have recently revolutionized the ideas of physiologists on the subject of a perfect dietary

These physiologists recently found that in addition to proteids, carbohydrates, fats, salts and water, which were formerly considered sufficient other bodies were necessary to ensure the proper growth and preservation of vitality These new bodies exist in very small quantities in fresh milk and certain vegetables, are of the nature of ferments or enzymes, and have been called **Vitamines** They are readily destroyed by such processes as the sterilization of milk and in the milling of flour by modern machinery so that it is advisable in the case of growing children or in those whose tissues have been wasted and devitalized by illness to ensure a proper supply and in Vitamogen we have them in a highly concentrated form

A fuller account of their nature and properties is given in a separate pamphlet * Some idea of their importance may be gathered from the fact that it was the discovery of **Vitamines** which enabled medical men to successfully cope with what are known as 'Deficiency Diseases, such as Beri beri and Pellagra which had previously baffled them completely and caused an appalling death rate in certain countries

Vitamogen also contains, in addition to Vitamines many other highly nutritive bodies, and is especially rich in **organic** phosphorus Phosphorus is essential for building up certain tissues of the body especially the nervous tissues which get worn out after many illnesses It is contained in many patent foods but in most of these it is contained in an inorganic form and is not absorbed by the body, whereas in **Vitamogen** it is contained in an organic state and is easily assimilated At an earlier period in medicine when the value of iron was discovered the same mistake was made—it was given in a crude inorganic form and it was not until organic forms of iron were prepared that its full value as a medicinal agent was realised

Bearing in mind these properties of **Vitamogen**, and as the result of practical experience, it is recommended as likely to be beneficial in the following cases —

As an Infants' Food

Vitamogen is readily taken and does not upset the digestion It is well known by doctors that children brought up on patent foods may apparently thrive and get fat but after a time their bones get soft and become bent and deformed owing to the development of rickets or scurvy rickets The reason is now known to be that all these foods, except **Vitamogen**, are deficient in the all important **Vitamines.**

Vitamogen is also useful for older children, owing to the fact, as we have pointed out that the **Vitamines** are to a large extent destroyed by the modern methods of preparing and cooking food.

When any form of Rickets or Scurvy is feared, the prompt use of **Vitamogen** will prevent the hideous deformities, such as bow legs, knock knees flat-foot, pigeon breasts, &c which result in untreated cases, and frequently necessitate operative treatment.

In any form of Nervous Disease, such as Neurasthenia, Hysteria Neuritis, &c The marvellous effects of **Vitamines** on nervous tissues have been well brought out in the treatment of Beri-beri which depends on a wasting of the nerves It is also useful in the nervous prostration which follows upon any severe illness such as influenza.

Vitamogen is useful as a general tonic when one is run down and feeling out of sorts especially if losing weight, owing to its property of aiding the body to form fresh tissues to replace those which have been wasted It must be remembered that **Vitamogen** not only contains all the essentials of a perfect food but enables the body to utilise other food to better advantage owing to the action of **Vitamine** as a ferment

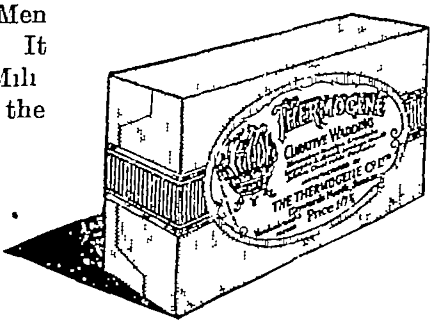
THERMOGENE
CURATIVE WADDING

gives the patient that tranquility and freedom from pain that speeds recovery . .

THERMOGENE is largely recommended by Medical Men throughout the country It is used in Naval and Military Hospitals and by the British Red Cross

We shall be pleased to send you a full sized package of Thermogene on receipt of your professional card, addressed to Thermogene Bureau L 28, Haywards Heath, Sussex.



THERMOGENE proved relief for

- Rheumatism
- Bronchitis
- Lumbago
- Neuralgia
- Sciatica
- Chest Colds
- Sore Throats
- Sprains
- Muscular Pains
